# CONSERVATION OF WORLD RESOURCES

THE Materials Policy Commission, established by President Truman on January 22, 1951, to make a long-range study of the materials problem of the United States, having regard to the needs and resources of friendly nations, was also charged with assisting the formulation of materials policy. The Commission was assisted by a comprehensive staff, as well as by a panel of the National Research Council and by numerous industrial firms, universities and other bodies. The work of the Commission has now been made available in a comprehensive report* running to five volumes, of which the first, entitled "Foundations for Growth and Security", embodies the bulk of the findings and recommendations, constituting a summary and broad analysis of the whole problem. With the fourth volume, "The Promise of Technology", it is the part of the report of most interest to the scientific worker, though the technologist will also be concerned with the second and third volumes, dealing with the outlook for key commodities and energy sources, respectively. The fifth volume presents a few of the basic studies prepared to assist the Commission.

The report of this Commission, known from its chairman, Mr. W. S. Paley, as the Paley Commission, was sent to Congress on July 1, 1951, and the National Security Resources Board was asked by President Truman to study the Commission's seventy-eight specific recommendations. A special body was set up by that Board to submit suggestions for implementing those recommendations as well as to assist in continuing the review of materials and energy policies and programmes. Originally the proposals of the National Security Resources Board were to be forthcoming within sixty days; but this task proved too great for the original time limit Nevertheless, the report of the Materials Policy Commission seems likely to result in definite action by the United States Government.

One of the most interesting features of the report is, however, the way it endorses an opinion expressed earlier in the year in "Facts and Figures for the Chemical Process Industries" by E. W. Pehrson, of the United States Bureau of Mines, that, from a mineral point of view, the United States are a 'have-not' nation in several indispensable minerals, and that for some of these the United States cannot hope to improve their position significantly through increased domestic output. Pehrson, in this article, listed thirty-eight important natural raw materials, and showed that in only nine of these are the United States self-sufficient, and for twelve they produce only ten per cent or less of their needs. The Paley Commission, in the first volume of its report, lists the production and reserves of twenty-two key materials in the free world, on all of which the United States are already substantially reliant or likely to become more reliant. Furthermore, with but 6·3 per cent of the world's population, the United States use 45 per cent of the world's minerals and are responsible for 50 per cent of the world's industrial output.

---

* Resources for Freedom. (A Report to the President by the President's Materials Policy Commission.) Vol. 1: Foundations for Growth and Security. Pp. viii+184. 1.25 dollars. Vol 4: The Promise of Technology. Pp x+228. 1.75 dollars. (Washington, D.C.: Government Printing Office, 1952.)

During the first fifty years of this century, the population of the United States has doubled, while the national output increased five times. While the consumption of agricultural products of all kinds, including food, increased two and a quarter times, the consumption of minerals, including fuels, increased sixfold. By 1950, in comparison with 1900, the output of coal had increased two and a half times, of copper three times, of iron ore three and a half times, of zinc four times, of natural gas twenty-sixfold, and of crude oil thirtyfold. This trend is expected to continue. It is estimated that by 1975 the demand for minerals as a whole will be twice as heavy as in 1950, though it is difficult to forecast the increased demand for any particular material.

To readers of the report outside the United States the most interesting feature, however, in its analysis of the materials situation is not the realization by the United States of the worsening relationship between their requirements and their means of satisfying them, but rather the outlook revealed by the Commission. There is official recognition that supplies are not inexhaustible, that even the United States must learn to be less wasteful of their natural resources of minerals, great as they are, and must accept the necessity of re-using the products of those resources many times over, and improve their techniques for the discovery and development of mineral resources. The Paley Commission points out that by making fuller use of known resources either by the avoidance of wastes, the exploitation of materials of lower grade or quality, or the utilization of waste products, the supplies of domestic materials can be expanded. This is largely a matter of expanding technology, though new physical knowledge may also be required.

Both factors contribute to the improvement which could result by shifting from the use of scarce to more abundant materials, or the more economical use of materials which comes when they are used under conditions having closer regard alike to their intrinsic properties and to the purpose to be served. Whatever advantage can be drawn from the synthesis of new materials to relieve existing shortages, the recovery of valuable materials from waste products or scrap, the prevention of corrosion and the reduction of losses in storage or transport depend on technological skill and scientific knowledge. Furthermore, they may also determine the capacity of the United States for dealing with what the Commission describes as the real threat in their materials problem.

This threat does not relate to absolute shortages but is due to the insidiously rising real costs—the hours of human work and amounts of capital required to bring a pound of industrial material or a unit of energy into useful form. During most of the twentieth century these real costs of materials have been declining, and this decline has assisted in raising standards of living in the United States. The Paley Commission believes that this trend has now been retarded, sometimes stopped and even reversed.

The central challenge of the materials problem in the United States is accordingly to meet expanding demands with expanding supplies, while averting a rise in real costs per unit. This question of costs is manifestly likely to be more difficult to overcome than in the past. Only in chemicals have real costs apparently declined faster in the past decade than in the previous four; and whereas wholesale prices of commodities in general advanced about 105 per cent between 1940 and 1950, that of zinc rose 119 per cent, petroleum 149 per cent, farm products 152 per cent, lead 157 per cent and lumber 218 per cent. Other materials, including aluminium, iron ore, nickel, sulphur and copper, rose less than the general average. But the rate of technological progress, which could help to counteract this situation, depends largely on the supply of scientifically trained personnel and the expansion of the fundamental scientific knowledge upon which technology is based; here the Paley Commission states that available evidence shows that the prospective flow of scientific men and engineers from the universities is alarmingly below apparent needs.

The Commission accepts the view that the United States have been less assiduous in increasing the store of fundamental knowledge than in applying such knowledge in industry, and that fundamental research in the United States should be more in balance with the expenditure of effort on applied research and development. It does not believe, however, that the United States Government has a philosophy of research commensurate with its present responsibilities for the allocation of financial support. At no point in the government organization can a comprehensive picture be obtained of the pattern of technological activity financed by the Government or an appraisal of that pattern.

In general terms, the Commission formulates six main tasks for technology: the fostering of new techniques for discovery; the utilization of new materials; the broader application of the principle of re-cycling; the handling of low concentrations of useful materials; the development and more economic use of renewable resources, such as solar energy; and the use of more-abundant materials to lessen or eliminate the use of a scarce material. These are dealt with in a subsequent chapter in the first volume, but detailed discussion is reserved for the fourth volume, in which specific problems are indicated. Here we can only consider the Commission's further judgment of the United States resources of trained man-power and their direction, which are examined in the chapter on "Government and Materials Research".

The United States are estimated to have roughly 625,000 scientific workers and engineers, of whom some 76,000 scientists and 59,000 engineers are engaged in research—nearly 60 per cent in industrial laboratories, about 20 per cent in government laboratories and 20 per cent in educational institutions, scientific foundations, and the like. As already indicated, the Commission concurs in the view that there is likely to be an acute shortage of technical man-power in the immediate future, and it recommends that both industry and the government should give the maximum support to programmes for advanced training consistent with the number of young scientific workers willing and able to continue their work. It also recommends that the appropriation of the National Science Foundation should be increased to the limit of 15 million dollars which Congress inserted into its basic Act, and that Congress should re-examine the bases upon which it set this limit so low.

The most pressing need, however, is for better co-ordination. The Commission believes that establishment of an active co-ordinating body is essential for shaping and executing a comprehensive, effective national policy of materials research. Such an organization would estimate and appraise the impact of technology and other forces upon supply. It would, for example, revise continually estimates of reserves in the light of new discoveries and the development of new uses and methods; estimate annually requirements of supplies at least ten years into the future on the basis of scientific and technological developments, as well as data on domestic production and consumption, and imports and exports; report potential shortages of important materials far enough in advance to permit corrective action; and maintain an up-to-date list of the materials research and development projects that should be undertaken. For such projects that cannot normally be assumed by industry, it would consult with the appropriate advisory bodies and, if necessary, bring the problem before the President or Congress. Such an organization would necessarily occupy a high place in the structure of the Federal Government and maintain close relations with the National Science Foundation and many other government agencies as well as with industry. The Commission recommends that the National Security Resources Board should be directed to provide such a co-ordinating service.

Whatever action may be taken on the Paley Commission's report in the United States cannot affect its value as a record of a reasonable appraisal of the situation over the next twenty-five years. Moreover, although in the lineage of Vannevar Bush's "Science, the Endless Frontier" and the Steelman report on "Science and Public Policy", it does more than record the view that the United States should be increasingly concerned with the conservation of resources: it asserts that the problem is one for the free world as a whole, and in which international co-operation is indispensable. The major premise of the report is, in fact, that the overall objective of a national materials policy for the United States should be to ensure an adequate and dependable flow of materials at the lowest cost consistent with national security and with the welfare of friendly nations. The Commission recommends that increasing emphasis be given under the United States programmes of technical assistance to under-developed areas for geological survey, preliminary exploration, and advice on mining technology. Support for these programmes should be increased to as much as four million dollars a year; but the extension of technical assistance in these fields should be accompanied by assurances to the United States that the recipient country will promote conditions favourable to developing such resources as may be discovered.

This objective inquiry has thus summoned the United States to conserve natural resources and co-ordinate them along with those of the other free nations to the ends of common growth, common safety and common welfare, almost simultaneously with Prof. A. V. Hill's reference to this question of world resources and world population in his presidential address to the British Association. Prof. Hill emphasized the challenge of the present situation to the responsible use of knowledge and the combined resources of science, humanity and statesmanship. The Paley Commission affirms its belief in the principle of growth and in private enterprise as the most effective means of performing industrial tasks in the United States; but it believes also that the destinies of the United States are inextricably bound up with those of the free world. There is much technical detail of wide interest to be found in these reports, but there is nothing more encouraging or more widely welcome than the evidence they contain of this spirit of co-operation and of readiness to approach the common problem of raising the standards of living of the free world as a whole, responsibly and imaginatively, with all the resources which science and technology can put at the disposal of statesmanship.

## THE SOLAR SYSTEM

### The Origin of the Earth

By Prof. W. M. Smart. Pp. viii+239+8 plates. (Cambridge: At the University Press, 1951.) 12*s*. 6*d*. net.

PROF. W. M. SMART has written this book for the general educated reader, who, in the first part, will find an admirably descriptive account of the solar system, which is complete in itself. The material is presented so as to lead up to the conclusion that the uniformities of orbital and rotational motions in the solar system are so pronounced as to make it very probable that the whole system must have come into being as the result of a single cosmical process. There are exceptions to these uniformities, the most striking being the existence of retrograde satellites. But there is a rational explanation; it is significant that the retrograde satellites are mainly to be found at the outermost fringes of the planetary systems concerned. To quote Prof. Smart: "There is perhaps a little justification for the suggestion that the satellites not conforming to the majority rule may have been originally minor planets which, through the interplay of planetary and other attractions, have been captured by the parent planets".

Having decided that the solar system originated as the result of a single cosmical process, the next question is: When did this happen? The second part of the book is devoted to the answer to this question, and an obvious starting-point is the age of the earth. Prof. Smart recalls the nineteenth-century controversy between Kelvin and the geologists, and he then gives an excellent résumé of the main facts of radioactive and nuclear phenomena, leading up to a clear account of the radioactive method of determining the age of the earth's crust, which is tied down to something between two and four thousand million years. He then passes on to an account of the astronomical evidence which leads to estimates of the ages of the moon, sun and universe. The evidence from these phenomena of the expansion of the universe is outlined, leading to the conclusion that "we are left with a time scale of a few thousand million years within which the universe has reached its present development from an initial state of high concentration. The evidence from the lengthening of the day as a consequence of tidal friction leads to the conclusion that about 4,000 million years ago the moon's centre was but 8,000 miles from the earth's centre, and that then the period of orbital revolution of the moon was equal to the rotational period of the earth, both being about 4 hours". The further suggestion seems to be unavoidable that the moon had then just been formed from the earth, from which it follows that the age of the moon is about 4,000 million years at most.

As regards the age of the sun, Prof. Smart indicates how current ideas of the source of stellar energy lead to the conclusion that the sun's age "must then be much less than 8,000 million years". I feel that in this part of his book Prof. Smart may have produced an impression in the general reader's mind which is rather too dogmatic. He gives an admirable account of the known thermo-nuclear reactions which may have been effective in the life-history of the sun. But I think he could have made it clearer that our knowledge of these processes is probably incomplete and that other nuclear processes, of which at present we are ignorant, may have been effective. Until the method of synthesis of the more complex nuclei is understood, it is probably imprudent to be dogmatic. But having said this much, I hasten to add that the general reader will find a fascinating and well-written account of those thermo-nuclear reactions which have been studied and are now well understood.

There remains the question of the exact mechanism of the cosmical process whereby the solar system was formed. The answer really is that we do not know, and in the third part of the book all that Prof. Smart can do is to give an account of the various theories that have been advanced. He records the conclusion that "the scientific search for an answer to our final question has thus failed, up to date, to reach a solution agreeable to astronomers other than those perhaps who individually are concerned with the formation of a particular theory". A very sound and salutary conclusion !

The high standard of presentation is only what one expects from the Cambridge University Press. The book is excellently illustrated.

W. M. H. GREAVES

# PREHISTORY OF UGANDA

**The Pleistocene Geology and Prehistory of Uganda**
Part 2: Prehistory. By Dr. C. van Riet Lowe. (Geological Survey of Uganda, Memoir No. 6.) Pp. x+113+54 plates. (Entebbe: Geological Survey of Uganda, 1952.)

PROF. C. VAN RIET LOWE, of the University of the Witwatersrand, Johannesburg, has won a great reputation among archæologists for the work he has accomplished on the prehistory of South Africa. What then could be more fortunate than the collaboration of a man who knows as much as he does of the prehistory of the subcontinent with a colleague like Mr. E. J. Wayland, the director of the Geological Survey of Uganda—a man whose knowledge of his subject is unrivalled and who shares Prof. Lowe's love for prehistory ! Part 1 of Memoir No. 6 of the Geological Survey of Uganda has yet to appear, and in it Mr. Wayland will deal with the Pleistocene geology of the Uganda area ; it is to be hoped that he will not delay too long in publishing the fruits of his researches. Meanwhile, and happily, Part 2 ("Prehistory") of the Memoir has appeared, the result of some months of field- and museum-work in Uganda carried out in 1939 by Prof. Lowe, who worked at Mr. Wayland's sites with him and collaborated very closely. The work is exactly what one could have hoped for—a straightforward and lucid account of the Stone Age cultures of Uganda based on the geological and archæological investigations of Mr. Wayland.

It is perhaps to be regretted that the author was unable, as he states, to examine an earlier work on the area—Mr. T. P. O'Brien's "The Prehistory of the Uganda Protectorate"—while he was working in the country. One questions whether a most understandable desire to avoid entering the lists of East African prehistoric controversialists really does excuse the ignoring of this book ; for though O'Brien was not a geologist, he did have geological advice, including much kind help from Mr. Wayland, and had some experience in typology—and he did produce an impressive volume. It was always clear that his presentation of the story was open to criticism ; in this case, for example, it would seem that Prof. Lowe does not agree with all his conclusions, such as the dating of the Kafuan culture ; but it would have been a great help to prehistorians who have not worked in Uganda to have had the criticisms of the work of Prof. Lowe's predecessor from the pen of one who does know the country.

The memoir opens with a historical review—necessarily mainly an account of Wayland's connexion with Uganda. While not going into details, the geological setting is here given and, a little later, there is a diagrammatic section of the Kagera river valley near Nsongezi showing terraces and the 'M', 'N' and 'O' horizons. There are chapters on the various cultures, starting with the Kafuan and reviewing the African Chellean, the African Acheulean, the Sangoan, and the Upper and Epi-palæolithic cultures and concluding with the Neolithic. In dealing with the Magosian culture, in the publication of which I was proud to be associated with Mr. Wayland in 1932, Prof. Lowe regrets that as all the material was sent to Cambridge he can only summarize the descriptions given in the paper referred to. There are thus no illustrations of the Magosian industry in this book—a notable lack in such a definitive work on the prehistory of the country. Yet reproduction of the original drawings or a choice re-drawing of the specimens could easily have been arranged. A brief but excellent summary and conclusions, with a useful table of climatic and geological correlations and, later, a bibliography, complete the text of 113 pages. Commenting on the surprising absence of any expression of the 'Capsio-Aurignacian complex' in Uganda, the author suggests that this may have been due to the lack of any fine-grained material such as flint, obsidian or indurated shale suitable for the manufacture of blade-and-burin industries. I have always felt that early man was very much at the mercy of physical Nature and feel sure that, as prehistorians discussing distribution maps, we often pay too little attention to this kind of circumstance. Lastly come fifty-four full quarto pages of illustrations of stone industries. These are well-chosen and very well drawn, many of them from the gifted pen of Mrs. Leakey—and it is no easy matter to interpret specimens of fairly crude industries when they are made from coarse-grained materials lacking the clearly defined flake intersections of flint and similar materials.

Altogether Prof. van Riet Lowe is to be heartily congratulated on having accomplished so much in his visits to Uganda (none of them very long), on having written a clear and much-needed account of the industries of the country founded on sound geological premises, and on having made available for study in the illustrations a large number of stone implements of various ages and cultures. M. C. BURKITT

# 'MAXWELL'S SPOT' IN COLOUR VISION

New Means of Studying Color Blindness and Normal Foveal Color Vision

With some Results and their Genetical Implications. By G. L. Walls and R. W. Mathews. (University of California Publications in Psychology, Vol. 7, No. 1.) Pp. iv+172. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1952.) 2.50 dollars.

THE storms that periodically affect the world of colour show few signs of abating, and a fresh disturbance from the west, indeed from as far west as California, is heralded by this monograph. Dr. G. L. Walls is already well known as the author of "The Vertebrate Eye and its Adaptive Radiation", but the present work is in no sense a staid text-book. On the contrary, it is a trenchant criticism of many orthodox views and many orthodox workers, and perhaps we should be grateful that at least two British men of science in this field, Dr. W. S. Stiles and Dr. F. H. G. Pitt, emerge relatively unscathed.

For once, however, it is not the three-component theory of colour vision that is under attack. At the outset, the authors make it clear that they are staunch supporters of this theory, and, while their main theme concerns defective colour vision, it is their views on the yellow macular pigment that will probably create the greatest interest. A yellow pigment is believed by many authorities on vision to occupy the central macular area of the retina, and variations in its density are commonly regarded as a major cause of individual differences of colour perception and colour matching. The present authors do not actually deny the existence of the pigment, but they do deny that it plays the important part that is frequently attributed to it.

A subjective demonstration of the macula is obtained when a uniform area of light such as the sky is viewed through a filter which transmits mainly at the far red and far violet ends of the spectrum. A diffusely defined reddish area is seen projected against the sky, and, as the gaze is directed from one part of the sky to another, so the spot follows the direction of view. It quickly disappears owing to local adaptation of the retina, but is restored to view if the filter is momentarily removed and then replaced. Sometimes the spot can be seen, without the aid of a filter, projected on a material dyed with a dichroic dye, although such dyes are normally avoided both because of their apparent spottiness and their marked change of colour with quality of the lighting.

James Clerk Maxwell studied this spot in some detail, and it is often referred to as 'Maxwell's spot'. An obvious and commonly held explanation was absorption of the blue radiation by the yellow macular pigment, and it is this explanation that Walls and Mathews flatly reject. They have been to considerable trouble to discover a filter which shows the effect as clearly as possible, and, with the aid of an experimental Wratten filter, detailed structure within the spot can be observed. The structure varies considerably from observer to observer and even between the right and left eyes of a given observer, but most often a central red spot subtending about $\frac{1}{4}$° is seen, and then an annular clearing of the same colour as the background, surrounded by a further red zone the diameter of which is some 3–4°. Occasionally, a tiny pip of the colour of the background is located at the centre of the central spot, an effect I can see in my left eye using Walls's filter, but not in the right.

Walls and Mathews point out with some logic that a yellow pigment impregnated in the retinal tissue could scarcely account for the structure of Maxwell's spot, since the retina is thinnest in the central $\frac{1}{4}$° of the fovea in just the area where the blue absorption should be greatest. They therefore attribute the phenomenon to variations in distribution of the retinal colour receptors, and they point in particular to the recent experiments in foveal tritanopia (which they call tetartanopia) as evidence that the blue receptors are missing in the foveal centre.

A number of other arguments are assembled to demolish the macular hypothesis, including the discovery that one group of colour-defectives, the deuteranopes, are unable to see the Maxwell spot. The latter half of the monograph is, in fact, mainly devoted to a description of the spots seen by colour-defectives and to a discussion of the observation as a colour vision test.

There is much here that deserves detailed study, and the analysis is undoubtedly made more difficult by the fact that in some respects both a yellow pigment and absence of blue receptors could produce rather similar effects. It does no harm for orthodoxy to be subject to the fierce criticism that we have here, but not all the arguments are equally valid. Many people would probably give greater weight to the histological arguments if reference had been made to Polyak's work. Then the authors criticize the use of data derived by calculation from the C.I.E. colorimetric system in place of direct experimental observations, yet their own neutral-point determinations were calculated on the C.I.E. chromaticity chart.

Perhaps the main misinterpretation, however, is in attributing colour-matching differences to differences in receptor distribution. Two different physical stimuli that have the same colour would remain a match however much the proportions of red to green to blue receptors were changed in the area of the retina viewing the two lights. The appearance of the lights would change, but they would still match. On the other hand, if the spectral sensitivities of the receptors were altered, or if a colour filter were introduced in the two beams, the match would break down.

Actually, colour matches differ from one observer to another very much as if a yellow filter of differing density had been introduced, hence the argument for the yellow macular pigment.

Yet difficulties do remain, and we can still be grateful to the authors of this monograph for their ruthless exposure of some of the fallacies of the pigmentary theory of Maxwell's spot without necessarily accepting all their arguments and conclusions.

W. D. WRIGHT

# TEXT-BOOK OF PLANT PHYSIOLOGY

## Principles of Plant Physiology

By James Bonner and Arthur W. Galston. (A Series of Biology Texts.) Pp. x+499. (San Francisco: W. H. Freeman and Co.; London: Bailey Bros. and Swinfen, Ltd., 1952.) 5.50 dollars; 47*s*.

DESPITE (or perhaps because of) the rapid progress during the past twenty years in the elucidation of plant physiology, text-books in this field of natural knowledge have remained notoriously few and far between. The appearance of a new one is thus an event of unusual interest.

This new volume, originating chiefly from the California Institute of Technology, is distinguished especially by the excellence of its treatment of the more biochemical aspects of the activities of the plant, and there are admirable chapters on photosynthesis, carbohydrate metabolism, respiration, nitrogen metabolism and enzyme action. The capacity and enthusiasm of the authors are, however, by no means exhausted by their labours on nutrition and metabolism, as is shown when they proceed, in the last third of the book, to give a stimulating and authoritative treatment of growth and development, in which the plant hormones, tissue culture and photoperiodism receive especial attention.

In general the information provided is thoroughly up to date, and, though references are not cited in the text, a short list of sources is appended to each chapter. The book as a whole is written at a level approximating to that of a general degree course in botany, but in biochemical and some other aspects the standard of treatment is nearer to that of a special course. Omissions that may be noted include a failure to attempt an adequate explanation of root pressure, or to mention frequently observed phenomena such as guttation, nastic movements, haptotropism or nutation. Minor objection could be taken to a preliminary statement on p. 11, which might be interpreted to mean that the oxygen of photosynthesis originates from carbon dioxide—the correct position on this is of course clearly indicated later in the chapter—and also to a slight uncertainty in the text as to whether or not the authors intend photosynthesis to be reckoned as a part of the metabolism of the plant.

In contrast with most other text-books on plant physiology, this one is copiously illustrated by means of drawings, diagrams, cartoons and graphs, to a total of 218. Many of these are excellent and some decidedly novel, such as that in which the familiar Askenasy apparatus is depicted as seen obliquely from above. But a few of the illustrations fall below the high standard set by the text. Fig. 11–9, purporting to illustrate the legume root nodule, is decidedly crude. The diagrams referring to plasmolysis fail to accord with the text in that they show no overall shrinkage in the size of the cell. The seedlings portrayed in Fig. 14–4 and stated to be "beans" seem more likely to be those of a cucurbit.

These minor criticisms do not detract significantly from the assessment of this new work as a notable achievement. It is written in a lucid and interesting style, and is printed in a large, easily read type. A first reading has yielded only a single misprint. In so far as the rather high price permits of it, this text-book should be in the hands of all students reading for a general or special degree in botany.

G. BOND

# PLANT RESPIRATION

## Respiration in Plants

By Prof. Walter Stiles and Prof. William Leach. (Methuen's Monographs on Biological Subjects.) Pp. vii+172. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1952.) 10*s*. 6*d*. net.

THIS little book was first published in 1932 and no monograph of plant respiration has appeared during the succeeding twenty years. It has therefore carried a heavier burden than perhaps even its authors anticipated, and, meanwhile, much has happened to the subject it describes. The foundations of the study of plant respiration were firmly laid about the start of the century, so it would be too much to say that the progress of the past twenty years has been revolutionary; but it has advanced to new levels and depends on different tools.

In preparing the third edition it has not been found necessary to alter the plan of the book, or to rewrite the first three of its four chapters, though a number of important additions have been introduced. The pages of text have been increased from 108 to 142, and 21 of the new pages are in the last chapter, which has been extensively rewritten. This is a fair reflexion of the present emphasis on the study of intermediate stages and chemical mechanisms.

The description of so complex a branch of metabolism within such narrow limits necessarily assumes a great deal of background knowledge on the part of the reader—perhaps about the amount commonly assumed in advanced lectures. It also necessitates the making of statements—such as that the end-products of aerobic respiration are the same as those of hexose combustion—without much evidence or discussion. It is presumably for the same reasons that one might be led to suppose that virtually the whole energy turnover of anaerobic respiration may be usefully transferred. To keep such difficulties within bounds, the authors have limited their choice of topics, and have in general succeeded in giving good grounds for the opinions they have adopted. While it would be difficult always to agree with them, it is good to note the caution with which they approach controversial matters. It is refreshing to find in so brief an account more than one idea of the fate of pyruvic acid and a reluctance merely to assume the identity of anaerobic respiration and alcoholic fermentation.

The changes noted in this new edition are all for the good; and, even when setting the first edition within the framework of its time, the new edition seems a better book and likely to be even more useful to students than its predecessor.

W. O. JAMES

# 'KRILIUM' AND SYNTHETIC SOIL CONDITIONERS

By Prof. J. H. QUASTEL, F.R.S.

Biochemistry Department, McGill University, Montreal

THE announcement of a synthetic soil conditioner, for the improvement of soil structure on a wide scale, was first made at a meeting of the American Association for the Advancement of Science held in Philadelphia on December 29, 1951, where a symposium on the improvement of soil structure by the application of organic matter took place. The papers read at this symposium have been published[1], and I have given a summary of them[2]. The present article is intended to give some account of the development and properties of soil conditioners.

## Soil Organic Matter and Soil Structure

The organic matter of soil plays an essential part in securing in soil the structure that is required for high fertility. The maintenance of the supply of organic matter to arable soils is, indeed, a matter of the greatest economic importance, for productive capacity is largely dependent upon it. It is a well-known fact that an arable soil regularly supplied with farmyard manure has an improved and more stable structure than the same soil that has not received organic additives. A more friable crumb structure resistant to disintegration by water is produced.

The organic matter of soil is primarily derived from the decomposition products of plants and from the products of autolysis of the immense numbers of micro-organisms which develop at the expense of substances of plant origin. A dynamic equilibrium exists in the soil between the numbers of bacteria, protozoa, yeasts and fungi, etc., that inhabit the soil and the organic matter being continually supplied by the decaying animal and vegetable tissues. Soil, therefore, normally contains a wide range of substances commonly classed as metabolites of animal and plant tissues. The speeds of change of these substances may be very great, the rates depending on the temperature, hydrogen ion concentration, aeration, availability of water and mineral content of the soil. A number of substances, derived from animal, plant or microbiological life, are, however, relatively resistant to breakdown, and these substances make up for the most part what is commonly known as organic matter. Such substances have the physical and chemical properties which together help to determine the structure and to influence the fertility of a soil.

Among the most characteristic of the products making up the soil organic matter is the black colloidal material having high hydrophilic power known as humus. This is a complex mixture of substances which was once thought to be formed solely from the cellulose in soil but which is, in fact, a natural system varying in composition and consisting largely of various derivatives of lignins, proteins and celluloses. This organic matter greatly influences the structure of a soil, and therefore the air–water relationships upon which the fertility of a soil depends.

The structure of a soil refers to the grouping or clustering of soil particles into aggregates or crumbs that at once influence water-movement, aeration and heat transfer. The granules that make up a soil of good structure may have a tremendous internal surface like that of a highly porous sponge, and it is in this large surface area that many of the biochemical and chemical changes take place that so markedly affect fertility. It is here where develop micro-organisms which convert organic nitrogenous compounds into the nitrate required by the plant roots, where metallic ions required by the plant are held by the soil in a base-exchangeable, or dissociable, form, where oxygen is dissolved and carbon dioxide is generated influencing local acidity and the metabolism of the plant root.

Aggregating substances are found uniformly distributed in soil crumbs. These consist[3] of organic compounds resulting from the decomposition of fresh organic matter and of a group of substances, including oxides of iron and aluminium, fats, waxes and resins, which are less efficient than the former as soil aggregators. It is well known that bacterial slimes and fungal mycelia play an important part in soil aggregation and the resistance of soils to erosion.

It is now known that among humus constituents are the polyuronides, substances related to the sugars and existing in a polymerized form. Forsyth[4] has, for example, isolated from soil a polysaccharide fraction containing uronic acid units. These are widely distributed in plants, composts and soils. The quantity of polyuronide present in soil varies with the type of soil[5], and there is evidence that the more fertile the soil the greater is the quantity of polyuronide present. Polyuronides include such well-known substances as pectic acid, alginic acid and a variety of bacterial polysaccharides. They compose the plant gums that are found in soils containing decaying vegetable matter. Bacterial polysaccharides such as the levans and dextrans also have marked aggregating effects on soils[6,7].

## Alginic Acid and Soil Structure

The large effect of a polyuronic acid, such as alginic acid, in increasing the water-holding power and crumb-stability of a soil was first shown by Quastel and Webley in 1947[8] in work carried out during 1941–45 in the Agricultural Research Council Unit of Soil Metabolism at the Rothamsted Experimental Station, Harpenden. These investigators used a manometric method of assessing the availability of oxygen to living cells, such as those provided by micro-organisms and plant roots, present in soils. The technique made it possible to investigate rapidly the immediate effects of the addition of various forms of organic matter on water-holding power and crumb-stability of soil. It was speedily found that the incorporation into soils of a variety of substances may greatly increase the amount of water that can be added to a soil before the availability of oxygen, defined as the aeration factor, falls. Sodium alginate, in particular, greatly increases both the water-holding power of a soil and its crumb-stability. Results

Table 1. AERATION FACTORS OF SOILS CONTAINING ALGINATE AND OTHER SOIL CONDITIONERS (Quastel and Webley, ref. 8)

| | Percentage water content per dry weight of soil | | | |
|---|---|---|---|---|
| | 25 | 37·5 | 50 | 62·5 |
| | Aeration factor values* | | | |
| Standard soil alone (a heavy clay) | 82·7 | 48·6 | 29·4 | 14·9 |
| + 0·1% sodium alginate | 88·4 | 76·4 | 42·7 | 17·2 |
| + 1·0% sodium alginate | 97·4 | 96·3 | 67·9 | 39·0 |
| Garden soil | 101·0 | 83·2 | 72·0 | 21·7 |
| + 1·0% sodium alginate | 108·4 | 112·0 | 123·4 | 96·0 |
| Standard soil alone | 86·4 | 55·1 | 27·0 | 16·0 |
| + 1% cellulose acetate | 97·1 | 89·2 | 58·6 | 31·7 |
| + 1% methyl cellulose | 91·7 | 88·8 | 53·7 | 21·5 |
| + 1% carboxymethylcellulose | 100·4 | 94·3 | 52·6 | 25·6 |
| + 2% farmyard manure (dried and ground) | 86·2 | 69·6 | 32·5 | 12·6 |
| + 2% horse dung | 104·0 | 107·5 | 83·7 | 76·1 |
| + 2% ground peat | 88·2 | 68·1 | 36·5 | 18·5 |
| + 2% extract of peat | 100·5 | 94·8 | 56·9 | 24·5 |
| + 2% extract of garden soil | 109·4 | 123·5 | 86·8 | 35·3 |

* Optimal aeration is given by aeration factor = 100

showing the effect of adding alginate to a standard soil depleted of organic matter are given in Table 1. It is seen that the addition of 1 per cent sodium alginate increases the aeration factor of a poor soil to that found for a fertile garden soil. The effect of the alginate rapidly increases to a maximum with increase of concentration. Even a garden soil, with a fairly high content of organic matter, showing good aeration at a high water-content, is affected by addition of alginate so as to improve the hydrophilic properties of the soil (Table 1).

## Soil Conditioners

Not only is a polyuronide effective in improving soil structure; cellulose esters such as cellulose acetate, methyl cellulose and carboxymethylcellulose will also improve the air–water relationships in soil (Table 1).

These are substances which may be termed soil conditioners. They improve the structure of a soil by increasing the water-holding power and the soil crumb-stability. This improvement of structure enables more oxygen to become available to the cells, micro-organisms or plant roots, present in soil, at the water contents that the cells need for their metabolism. The increased stability of the soil crumbs diminishes soil disintegration by weathering, etc., and hence diminishes soil erosion. Soil conditioners are not plant nutrients. They yield nothing of service to the plant itself. But, by altering the soil structure, they make more oxygen and water available to the plant roots.

The addition of farmyard manures greatly improves the air–water relationships and crumb-stability of soil, and so does the addition of sewage sludges, composts and refuses generally in proportion to the amount of organic matter present. Extracts of soils and peats may be also very effective (see Table 1) in accordance with their content of organic matter.

These observations make it clear that the commonly occurring forms of organic matter in soils and manures greatly improve the hydrophilic properties and crumb-stability of soils. Yet the practical importance of such substances is greatly dependent on the rate at which they decompose in soil and lose their improving properties. That the addition of alginate to a soil will improve the yield of a crop, grown under glass, was shown by Quastel and Webley[8] and confirmed by Owen[10] and by Hedrick and Mowry[11] (see Table 4); but it soon became certain that the fact that the polyuronide breaks down fairly rapidly in soil militates against its use on a wide scale as a soil conditioner. Again, relatively large quantities are required for the improvement of soil structure (perhaps 5–10 tons per acre) and they may cause harmful effects due to the liberation of cations which have to be added to the polyuronic acid to preserve neutrality.

It was my objective to find a substance, or substances, which would have the improving effects of alginate on soil structure but which would be relatively stable in soil. For use on a large scale, as a substitute for the organic matter of manures and composts, such substances would have to be, weight for weight, more effective than alginate, and without harmful effects on micro-organisms, plants or animals. The advantages of these substances for the improvement of fertility in soils relatively poor in, or depleted of, organic matter would be enormous.

Thanks to the recent discoveries of the scientific staff of the Monsanto Chemical Company, with whose investigations in the field of soil conditioners I have been associated, such substances are now available.

## Synthetic Soil Conditioners

Hedrick and Mowry, of the scientific staff of the Monsanto Chemical Co., using initially the manometric technique adopted by Quastel and Webley, and later a modification of the wet-sieving technique of Yoder[12], began the screening of a large number of substances, most of which were synthesized in the Monsanto laboratories, to see if any had improving effects on soil structure. They soon found that only certain water-soluble polymeric electrolytes of high molecular weight were effective at the extremely low concentrations required by practical considerations. One of the most active substances was made by the hydrolysis of polyacrylonitrile to what is predominantly a sodium salt of a polyacid. Other substances that showed excellent effects were also polymers of nearly related structure. These substances had very great improving effects on soil aeration and soil aggregation[11]. A few typical results are shown in Table 2.

Table 2. AERATION FACTORS OF SOILS TREATED WITH POLYELECTROLYTES (Hedrick and Mowry, ref. 11)

| Chemical added to standard soil (sandy loam) | Concentration (percentage) | Aeration factors | | | |
|---|---|---|---|---|---|
| | | 25% water | 37·5% water | 50% water | 62·5% water |
| Standard soil alone | — | 83 | 55 | small | small |
| Sodium alginate | 1·0 | 108 | 106 | 73 | 20 |
| Sodium alginate | 0·1 | 118 | 85 | 28 | small |
| Pectin | 1·0 | 86 | 77 | small | small |
| Lignin | 1·0 | 90 | 67 | small | small |
| *CRD*-186 | 1·0 | 130 | 99 | 63 | 30 |
| *CRD*-186 | 0·1 | 128 | 92 | 66 | 40 |
| *CRD*-189 | 0·1 | 113 | 99 | 72 | 35 |

The two materials on which most work was carried out were *CRD*-189, the sodium salt of a hydrolysed polyacrylonitrile, and *CRD*-186, another carboxylated polymer used as a partial calcium salt. Both these polymers are polyanions, that is, they contain recurring carboxyl groups along the carbon chain.

These polymers have a very great effect upon crumb (or aggregate)-stability and upon soil aeration. A comparison of the effects of preparations of

Table 3. PARTICLES < 0·25 mm. AGGREGATED INTO WATER-STABLE AGGREGATES > 0·25 mm. BY TREATMENT WITH *CRD*-186

(Hedrick and Mowry, ref. 11)

| Soil | Percentage aggregation | | |
|---|---|---|---|
| | Untreated | 0·02% *CRD*-186 | 0·1% *CRD*-186 |
| Paulding clay | 26 | 29 | 63 |
| Sacramento clay | 8 | 25 | 47 |
| Miami silt loam | 7 | 48 | 96 |
| Cherokee silt loam | 7 | 34 | 94 |
| Pond loam | 1 | 38 | 87 |
| Renville loam | 5 | 13 | 57 |
| Barboursville sandy loam | 11 | 78 | 86 |

*CRD*-186 and *CRD*-189 with those of several other substances on the aeration values of a sandy loam is shown in Table 2. *CRD*-186 and *CRD*-189 gave better aeration values at levels of 0·1 per cent in soil than any of the other materials at 1 per cent. This effect of *CRD*-186 occurs with a large variety of soils. The aggregate stability, as measured by wet-sieving technique, was greatly increased by application of the polymers to the soil, the quantity of large crumbs being increased with a higher rate of application of the polymers. Results of laboratory applications of *CRD*-186 to a number of structurally deficient soils are shown in Table 3. Very pronounced improvement in the workability of all soils treated with *CRD*-186 and *CRD*-189 took place. They became crumbly and friable at high water contents.

Although the primary effect of the polyelectrolyte is on aggregate stability, the percolation-rate through a treated soil may show a hundred-fold increase over an untreated soil. The moisture equivalent of a soil is also improved, and evidence from experiments on the wilting of plants has indicated that all the increase in water held by the soil is available for plant growth. Treatment of soil with the polyelectrolyte results in a reduction of the rate of surface evaporation.

Crumbs of soil treated with *CRD*-186 have remained stable under constant perfusion with water and air for 32 months at 76° F., indicating negligible biological breakdown of the soil conditioner in this period. The untreated crumbs broke down in a few minutes under the same conditions.

An important question concerning the action of the synthetic soil conditioners was whether they affect adversely plant and animal life in the soil. The Warburg evaluation technique indicated that the polymers are not toxic to yeast or bacteria in the soil; moreover, the processes of nitrification are not disturbed. Spectroscopic analyses of kidney beans, wheat and radish plants grown in treated and control soils have indicated that nutrients and trace elements are not rendered unavailable in any way. Nor are the polymers toxic to earthworms, which have appeared in greater numbers in the more friable and well-aerated soil. Rats and chicks have been fed with relatively large doses of *CRD*-186 and *CRD*-189 with no apparent ill effect.

Table 4. EFFECT OF *CRD*-189 AND ORGANIC FERTILIZERS ON GROWTH OF RADISHES IN MIAMI SILT LOAM (Hedrick and Mowry, ref. 11)

| Treatment | Dosage (per cent) | Average radish weight factor |
|---|---|---|
| None | — | 1·0 |
| *CRD*-189 | 0·05 | 1·7 |
| *CRD*-189 + artificial fertilizer* | 0·05 | 3·4 |
| Sodium alginate | 1·0 | 0·04 |
| Sodium alginate + artificial fertilizer* | 1·0 | 2·6 |
| Commercial compost | 1·0 | 1·1 |
| Activated sewage sludge | 1·0 | 0·6 |
| Rotted cow manure | 1·0 | 2·3 |
| Peat | 1·0 | 1·1 |

* Artificial fertilizer is 0·1 per cent N.P.K. (6-10-4)

The effects of application of *CRD*-189 and of other substances to a silt loam on the growth of radishes are shown in the results of Hedrick and Mowry, given in Table 4. It will be noted that alginate in the presence of added artificial fertilizers gives excellent growth, though alone it induces little or no growth owing to its mobilization of available nitrogen due to its breakdown in the soil. The synthetic polymer shows no such inhibitive effect.

## Crop Yields

According to Allison[13] the application of *CRD*-186 and *CRD*-189 at rates of 0·025 per cent and 0·1 per cent to several saline and alkali soils from the western United States produce high water-stable aggregations, with considerable increases in permeability of soils. Crop yields were favourably affected. Sweet corn was grown on treated and untreated soils; whereas the untreated soils gave poor stands of corn owing to heavy crust formation, full stands were obtained on the treated soils. The quality of corn was excellent and yields were good despite the prevailing high temperatures during the experiments.

Further experiments indicated that administration of *CRD*-186 facilitated removal of salt and exchangeable sodium after irrigation of the soils, a property of importance in soil reclamation.

Martin, Taylor, Engibous and Burnett[14] found also that application of the conditioners to various soils greatly improved water-stable aggregation and such related properties as porosity and permeability. Crop yields, particularly those of corn, oats and carrots, were considerably increased. Some of their results with sweet corn and beet are shown in Table 5.

Table 5. EFFECT OF *CRD*-186 ON AGGREGATION AND SWEET CORN AND BEET YIELDS ON PAULDING CLAY

(Martin, Taylor, Engibous and Burnett, ref. 14)

| Treatment | Aggregation (particles >0·25 mm.) (%) | Sweet corn | | Red beets | |
|---|---|---|---|---|---|
| | | height (in.) | increase over untreated (%) | weight per 30-ft. row (lb.) | increase over untreated (%) |
| Untreated | 45 | 12·1 | — | 6·7 | — |
| 0·05% *CRD*-186 | 85 | 21·3 | 76 | 7·7 | 15 |
| 0·15% *CRD*-186 | 94 | 24·4 | 102 | 8·7 | 30 |

## Control of Soil Erosion

Equal in importance to the experiments showing the effects of soil conditioners on the improvement of crop yields on various soils are those demonstrating the remarkable effects of conditioners in the control of soil erosion. Work by Weeks and Colter[15] has shown that surface soil can be satisfactorily stabilized to the erosive action of rainfall by treating the surface with the soil conditioner. The permeable film produced by the conditioners not only stabilizes the soil, but also prevents run-off. The effect was much the same as that due to the application of a high rate of straw mulch. Addition of half to one pound of conditioner to 100 sq. ft. provided satisfactory protection to the soil. One set of results on the effects of artificial rainfall on experimental plots showed that erosion equal to a loss of 50 tons of soil per acre was reduced to a loss of 3 tons per acre by application of the soil conditioner.

## 'Krilium'

'Krilium' is the trade mark adopted by the Monsanto Chemical Company for substances such as *CRD*-186 and *CRD*-189 sold as soil conditioners. The advent of these conditioners heralds a new phase in agricultural science, of equal importance perhaps with that brought about by the first application of the artificial fertilizers. The possibilities of improvement of fertility in the semi-arid wastes of many parts of the world, which have suffered through neglect of proper cultivation or lack of application of organic matter, are very obvious. But apart from the important economic consequences of the administration to suitable soils of the synthetic soil conditioners, it is clear that these substances afford most valuable material for further studies of the relationship between organic matter and soil fertility.

# SCIENTIFIC CENTENARIES IN 1953

By JOAN M. EYLES

WHILE science, in the modern sense, is often taken to date from about 1600, a year marked, for example, by the publication of Gilbert's "De Magnete", its roots are to be found far back in earlier ages. No one would deny the right of the Greeks to have some mention in a history of science, and few would omit the name of Plato, who is said to have died in 347 B.C., 2,300 years ago. Many biologists, and geologists, too, have heard of Anaximander, who died two hundred years before Plato, in 547 B.C. To include, in this annual review, the names of men who flourished before the Christian era certainly requires a rather optimistic reliance on the accuracy of historical chronology. Our justification must be that, if absolute accuracy be demanded, it might become necessary to omit the names not only of such men, but also of natural philosophers who lived many centuries later. With this apology, we return to Anaximander (c. 611–547 B.C.), a citizen of Miletus, and pupil and friend of Thales, who was not only interested in astronomy and geography, but also believed that the first animals were generated from moisture, being thus the first teacher of the doctrine of abiogenesis. He also taught that the ancestors of men were of aquatic origin.

Plato (428–347 B.C.) must be regarded with mixed feelings. His attitude towards physical science, which he thought should be discussed as idealized by the mind rather than as presented by the senses, was called by Sir James Jeans a major disaster for physics. Others admire him for the immense stimulus he gave to the development of mathematics. He insisted on the value of mathematics in the development of logical thought, and over the entrance of his Academy was inscribed, "Let no one enter who is unacquainted with geometry". Although his interest in astronomy redeemed it from the reproach of atheism and thus made it respectable, his opinion that the perfection of the universe required planetary motion to be circular dominated astronomical thought for centuries, until the time of Kepler.

Passing over the Dark Ages, now being illuminated by the questing beams of historians, we come to the thirteenth century A.D., when the founding of a school of science in Oxford can be attributed to Robert Grosseteste, who was born at Stradbroke, Suffolk, about 1173, and died in 1253. Grosseteste studied at Oxford, and later lectured there, ultimately becoming chancellor of the University. About 1224 he was appointed rector of the school established by the Franciscans. Here one of his pupils was Roger Bacon, who said of his master, "One man alone, our Lord Robert, knew the sciences", and it was probably due to the early influence of Grosseteste that Bacon plunged so deeply into scientific studies. Grosseteste himself was one of the earliest of the experimental scientists, and was particularly interested in optics, which he considered to be the basic science. His writings include a discussion of vision, a treatise on the rainbow, and another on comets. He was made Bishop of Lincoln in 1235, an appointment which he held until his death on October 9, 1253.

Coming to more modern times, three men who died in 1553 must be mentioned here. They are Reinhold, the mathematician and astronomer, Fracastoro, the physician, and Servetus, who earned a niche in medical history for his remarks on the minor or pulmonary circulation. Erasmus Reinhold (1511–53) became professor of mathematics at Wittenberg, a university founded in 1502 and closely linked with Luther and the early days of the Reformation. Reinhold, a friend and colleague of Rheticus, who was the first disciple and staunch supporter of Copernicus, applied himself to recalculating to a greater degree of accuracy the tables given by Copernicus in his "De Revolutionibus", and these were published in 1551 as the "Prutenicae Tabulae" (so called in honour of Albert, Duke of Prussia, Reinhold's patron). These tables were well received at their first appearance, and were only supplanted by the "Tabulae Rudolphinae" of Kepler, published in 1627. Reinhold died on February 19, 1553, at Saalfeld, his birthplace, where he had fled in a vain attempt to escape the plague. A text-book on surveying, including mine surveying, which he had written, was published posthumously at Saalfeld in 1574. This was in use as a standard work in Germany for very many years (see *Nature*, 67, 42; 1902).

Girolamo Fracastoro (1483–1553) was a Veronese physician who studied at Padua for some years. The fact that Copernicus was a fellow student adds interest to his astronomical work, "Homocentrica". This is an elaborate and somewhat obscure attempt to offer a new planetary system. In it he made the important observation that comets' tails are always turned away from the sun. When, in 1517, certain excavations revealed fossil shells, Fracastoro's comment that they must be remains of once living creatures earned him a place in the history of geology. His fame, however, rests on two medical books. In one, a poem, "Syphilis sive Morbus Gallicus", he described the disease which came to be known by the title of the poem; and, in his later and more important work, "De Contagione", he classified for the first time modes of infection and gave detailed descriptions of a number of fevers, including typhus.

A younger contemporary of Fracastoro was the unfortunate Spaniard, Miguel Servet y Reves (1509–53), better known as Michael Servetus, who was burnt to death at the stake, at Geneva, by Calvinists for the heretical opinions expressed in his "Christianismi Restitutio", a copy of which was tied to his waist. It was in this book that Servetus described the passage of the blood through the lungs. His account could have attracted little attention at the time, for, of the edition of about a thousand copies, half were burnt with an effigy of Servetus by the Catholic Inquisitor at Vienne on June 17, 1553, and the other half, which had been sent to Frankfurt, were destroyed at the request of Calvin some months after Servetus's death on October 27. It was well over a century before anyone directed attention to his contribution to physiology.

Two naturalists born in 1553 were Thomas Moufet and Prospero Alpino. Moufet (1553–1604), the son of a Scottish haberdasher, was born in London and educated at Cambridge. He studied medicine and later became a fashionable physician. He is remembered for the "Theatrum Insectorum", the first British work devoted to insects, which, however, did not appear until thirty years after his death. It was based on the work of Thomas Penny; but the manuscript, which survives in the British Museum, has many excellent drawings by Moufet. Alpino, another physician, born at Marostica in the Republic of Venice on November 23, 1553, studied at Padua and took his doctor's degree there in 1578. He spent three years in Egypt, and afterwards published several works on the natural history of that country, the best known being his "De Plantis Aegypti Liber" (1592). He enriched the botanical garden at Padua with Egyptian plants.

No outstanding scientist seems to have died in 1653, but two men born in that year have some claim to fame. J. Conrad Peyer, a Swiss zoologist, has his name commemorated in Peyer's patches, the intestinal glands which he figured in 1677, though he was not the first to describe them. He was also the author of a monograph on the compound stomach of ruminants. Peyer died at Basle in 1712.

To have been deaf and dumb until the age of seven, and even after that age always to lack a normal voice and ear, would seem handicap enough in life without inviting further embarrassment by taking up the study of the physics of sound. Yet that was the choice of Joseph Sauveur, born at La Fleche on March 24, 1653. He was a student of the popular Rohault, and was elected to the Royal Academy of Sciences, Paris, in 1696. Although he has been described as the founder of acoustics, it has recently been shown (Lloyd, Ll. S., *Notes and Records Roy. Soc.*, 3, 149; 1941) that much of his work on harmonics had been anticipated by contributors to the *Philosophical Transactions*. He died in 1716.

Before noting bicentenaries, one cannot pass without remark the fact that in 1703, two hundred and fifty years ago, occurred the death of the famous Robert Hooke and the almost equally celebrated mathematician John Wallis.

The year 1753 is an epic one in the annals of natural history in Britain, for it was in the course of that year that Parliament passed "An Act for the Purchase of the Museum or Collection of Sir Hans Sloane and of the Harleian Collection of Manuscripts, and for providing one General Repository for the better reception and more convenient use of the said Collections", that is, virtually, for the foundation of the British Museum. Sloane had died on January 11, 1753, in his ninety-second year, and it was his wish that his enormous collections, which included 40,000 books, as well as manuscripts, coins, and botanical, zoological and mineralogical specimens from all over the world, should pass to the nation. He therefore instructed his trustees to offer them to the King or to Parliament for the sum of £20,000, which he believed to be less than a quarter of their true worth. If the offer was refused then other countries were to be approached, and he named the Royal Academies of Sciences at St. Petersburg, Paris, Berlin and Madrid, in that order. George II showed little interest in the offer when approached by Sloane's trustees, remarking, with good reason, that there was not £20,000 in the Treasury. Parliament, however, urged on by Speaker Onslow, passed the Act referred to above. To raise the necessary sum it was agreed to hold a national lottery, which was intended to produce £100,000. Although the lottery was successful in the latter aim, the traffic in tickets by the jobbers and gamblers who handled the business became a public scandal.

Sloane, the son of a Scot, was born in Ulster in 1660. As a student of botany and medicine in London he became friendly with John Ray and Robert Boyle. He continued his studies in France, and returned to London in 1684 with many rare plants and seeds. In 1687 he went as physician with the Duke of Albemarle to the West Indies. Here, during a stay of some fifteen months, he made an extensive collection of plants, animals and minerals. His collections grew steadily as the years passed, and he purchased or acquired by bequest those of other collectors. Sloane was elected a Fellow of the Royal Society in 1685, and became secretary in 1693. In many ways he did good work for the Society, and in 1727 he succeeded Sir Isaac Newton as president, only resigning fourteen years later, when he felt his advancing years no longer permitted him to discharge his duties satisfactorily He then retired to his country house in Chelsea, where his museum and belongings were removed, and where he died. His statue by Rysbrack still stands in the Chelsea Physic Garden, and the monument over his grave in Chelsea churchyard has been more fortunate than the church in escaping war damage.

Three days after Sloane, on January 14, 1753, another famous Fellow of the Royal Society died. This was Bishop Berkeley (1685–1753), the philosopher, who, like Sloane, was born in Ireland. Berkeley's philosophical works are well known, as well as his controversy with the mathematicians over the method of fluxions. A different aspect of his character is revealed by his cherished scheme to found a college in the Bermudas, where the English youth of the Plantations could study side by side with "the young American savages". Berkeley was actually successful in persuading Parliament to vote him £20,000 to promote his proposals; but, although he immediately crossed the Atlantic with his wife, and then spent three years in Rhode Island awaiting funds, he eventually despaired of receiving the money and returned to England in 1731. He died quite suddenly a few months after settling in Oxford, and was buried there in Christ Church.

Three other scientists who died in 1753 call for brief mention. Nicholas Fatio de Duillier (1664–1753) was a Swiss mathematician who spent much of his life in England, and was elected a Fellow of the Royal Society in 1688. He was prominent in the Newton–Leibniz controversy, being the first to accuse Leibniz of plagiarism. He demonstrated to the Royal Society the use of jewelled bearings for watches, and also wrote on navigation. Becoming involved with a group of religious fanatics, in 1707 he appeared in the pillory at Charing Cross for publishing prophecies likely "to terrify the Queen's people". After some years abroad he retired to Worcestershire, where he died on April 24 in his ninetieth year.

Georg Wilhelm Richmann, one of science's martyrs, was born at Pernau in 1711, and became professor of experimental philosophy at St. Petersburg in 1745. He deduced a formula for calculating the temperature of mixtures, which was used by Wilcke in his experiments on the melting of snow. Richmann met his end in an unusual way. An enthusiastic student of electric phenomena, he was killed in the summer of 1753 during a thunderstorm by a flash of lightning which passed through his body from a lightning collector with which he was experimenting. The strange manner of his death was made known in two communications to the *Philosophical Transactions*.

Thomas Melvill (1726–53), a Scot, was only twenty-six when in 1752 he communicated a paper to the Edinburgh Philosophical Society in which he described the examination through a prism of flames into which different salts had been introduced. These experiments establish him as one of the pioneers of spectrum analysis. He died in December of the following year at Geneva.

The stars of 1753 seem to have shone favourably for the birth of inventors, for six men born in that year whom we notice all had a strong bent towards practical science. The best known of them is Sir Benjamin Thompson, Count Rumford, who led a varied and colourful life. Born in Massachusetts on March 26, 1753, he arrived in England in 1776, his Royalist sympathies having made it advisable for him to leave America. In the War of Independence he served as an officer in the British Army, but at the end of the war, in 1783, he returned to England again. Soon afterwards he set out to visit Europe. In 1784 he entered the service of the Elector of Bavaria, and, becoming his principal adviser, he carried out many social reforms. It was during this period that he made in Munich his famous experiments on heat. He had been knighted by George III in 1784, and seven years later was created a Count of the Holy Roman Empire, when he chose to commemorate in his title the Massachusetts township (now Concord) with which he had close associations. Returning to London in 1798, he applied himself enthusiastically to drawing up proposals for founding a public institution "for diffusing the knowledge and facilitating the general introduction of useful mechanical inventions and improvements". These proposals led to the founding of the Royal Institution in 1799. In his house in Brompton Row (a little east of Brompton Oratory, in what is now Brompton Road) he installed the many improvements in heating to which he had devoted so much of his time. The house was freely exhibited to visitors from all classes of society, and for several years attracted curious sightseers. Its furniture included beds disguised by day as elegant sofas, built-in cupboards, and hinged panels which could be raised to form writing-tables near the fire or window. Rumford spent his last years in France, where he died at Auteuil at the age of sixty-one.

Another somewhat unusual character born in 1753 was Charles, third Earl Stanhope. Elected a Fellow of the Royal Society at the age of nineteen, he devoted much of his income to experiments in natural philosophy. He made two calculating machines, now in the Science Museum at South Kensington, and constructed the first iron printing press. The latter, together with his invention of stereotyping by a plaster process, he presented to the Clarendon Press in 1805, and they were in use for some years. Stanhope died in 1816. A man in a very different walk of life to the noble earl was Samuel Crompton (1753–1827), inventor of the spinning mule which did so much to raise the status of the cotton industry. Other contemporaries were Edward Troughton (1753–1835), the renowned maker of astronomical instruments, who received the Copley Medal of the Royal Society in 1809, and William Nicholson (1753–1815), who with Sir Anthony Carlisle was the first to construct a voltaic pile in Britain, and with it observed the electrolytic decomposition of water. He was also the founder and editor of *Nicholson's Journal*, one of the first of the independent scientific journals in Britain. We must also mention F. K. Achard (1753–1821), the German chemist who discovered a commercial method of extracting sugar from the sugar-beet, so laying the foundation of an industry which rapidly became of considerable economic importance.

In 1853, geological science suffered two losses in the deaths of C. L. von Buch (born 1774) and H. E. Strickland (born 1811). Von Buch had been a pupil of Werner at Freiberg and an intimate friend of Humboldt. He made many valuable contributions to geology, in particular a description of the Canary Islands, which he visited in 1815. He also made important observations on the change of sea-level along the Swedish coast, compiled the first geological map of Germany, and made notable contributions to palæontology. Von Buch reached the ripe age of seventy-nine; but Strickland was only forty-two when he was killed by a train while making geological observations in a railway cutting near Retford. He was the author of a number of geological and ornithological papers, and in 1850 was appointed deputy reader in geology at Oxford, during the illness of Buckland. Strickland was one of the founders of the Ray Society, and edited for the Society the "Bibliographia Zoologiæ et Geologiæ" based on the manuscripts of Agassiz, though on account of his untimely death the fourth volume was completed by his father-in-law, Sir William Jardine. Strickland was also joint author of a classic memoir on the dodo.

French scientists lost several of their number during 1853, the best known being Dominique François Jean Arago, physicist and astronomer, born near Perpignan in 1786. At the age of eighteen he became secretary to the Observatory in Paris, and two years later accompanied Jean Baptiste Biot to Spain in order to assist him in completing the meridional measurements begun by Delambre. After Biot had returned to Paris, Arago became involved in the most fantastic adventures, which included imprisonment in a fortress, escape in a fishing boat, and capture by a Spanish corsair. Eventually he arrived back in Paris, still in possession of the records of his survey, which he had preserved through all his vicissitudes. Soon after his return he was elected to the Academy of Sciences at the remarkably early age of twenty-three, and about the same time Napoleon appointed him as one of the astronomers of the Royal Observatory. Arago carried out notable researches on the polarization of light. He also discovered the "magnetism of rotation", which was not interpreted until Faraday discovered electro-magnetic induction. Arago received the Copley Medal of the Royal Society in 1825 and died on October 2, 1853. His compatriot, Auguste Laurent (1808–53), a brilliant young chemist who died a few months before, on April 15, had led a very different life from that of the accomplished and successful Arago. Always struggling against poverty, and apparently ostracized by his French colleagues, some of his experimental work was carried out in a damp cellar while he worked as assayer to the Mint. He is credited with a number of discoveries in the field of organic chemistry. He died of consumption, and his famous "Méthode de Chimie" was published posthumously. Another organic chemist, Leopold Gmelin (1788–1853), perhaps the best known of a distinguished German scientific family, died two days before the unfortunate Laurent. He was professor at Heidelberg, and the author of the great "Handbuch der Chemie", translated into English (1848–72) for the Cavendish Society by Henry Watts.

Other deaths in the same year were those of C. J. Doppler (born 1803), the Austrian physicist who discovered the principle named after him, K. J. B. Karsten (born 1782), the German mineralogist, and M. J. B. Orfila (born 1787), the celebrated toxicologist. In America the deaths were reported of Sears Cook Walker (born 1805), astronomer, and William Beaumont (born 1785), physiologist. The latter, an American surgeon, for many years made observations on the stomach of a French-Canadian trapper who had suffered a severe gunshot wound. The persistent opening in the wall of his stomach permitted Beaumont to make experiments which threw considerable light on the nature and flow of the gastric juice.

A number of particularly distinguished men were born in 1853, including four who received Nobel Prizes. Wilhelm Ostwald, born at Riga on September 2, held a professorship of chemistry at the Baltic Polytechnical School of Riga during 1883–87, and then became professor of physical chemistry at Leipzig. When he retired in 1905, at his own request, in order to devote himself to research, he was nominated by the Emperor of Germany as the first exchange professor with the United States. In 1909 he received the Nobel Prize for chemistry. His contributions to physical chemistry were numerous, and too well known to need detailing here; but it is worth recalling that in the industrial field he developed the process for producing nitric acid by the catalytic oxidation of ammonia, which became the main source of Germany's supply of nitric acid during the First World War. Ostwald died on April 4, 1932.

A contemporary of Ostwald's, who worked with him for a time at Leipzig, was Ernst Beckmann (1853–1923), who became director of the laboratory for applied chemistry there in 1897, a position he held until 1912. The Beckmann thermometer and Beckmann freezing-point apparatus for the determination of molecular weights are well known.

An outstanding figure of the period under review was the Dutch physicist, Hendrik Antoon Lorentz, born at Arnheim on July 18, 1853. At the age of twenty-five he was appointed professor of theoretical physics at Leyden, and occupied the chair there with great distinction for forty-five years. The Lorentz transformation, made known in 1903, became the basis of the theory of special relativity. With Zeeman, he was awarded the Nobel Prize for physics in 1902. He was a Foreign Member of the Royal Society, and received the Rumford Medal in 1908 and the Copley Medal in 1918. He died at Haarlem on February 4, 1928.

Another eminent Dutchman, only a few months younger than Lorentz, was the genial Heike Kamerlingh Onnes (1853–1926). Born at Groningen, he passed several years at Heidelberg under Bunsen and Kirchhoff. Appointed professor of experimental physics in Leyden in 1882, he founded the famous Cryogenic Laboratory, where he achieved his great triumph, the liquefaction of helium, in 1908. Like Lorentz, he was awarded a Nobel Prize for physics (1913), and was a Foreign Member of the Royal Society. A fellow student of Onnes at Heidelberg in 1872 was W. F. Hillebrand (1853–1925), the American geochemist, who after joining the U.S. Geological Survey in 1880 became specially distinguished for his analyses of rocks and minerals. He made many analyses of the mineral uraninite between 1882 and 1892, and was puzzled by the presence in it of an inert gas, afterwards identified by Ramsay in 1895 as helium. Later, his highly skilled analyses of radioactive minerals were used in determinations of the age of the earth by Holmes and others.

A distinguished Italian mathematician, M. M. G. Ricci (1853–1925), who developed the tensor calculus, also comes into this period.

In the biological sciences two men must be mentioned. Albrecht Kossel (1853–1927), trained as a physiologist, devoted his researches to chemical subjects and became one of the leaders in the then new science of biochemistry. He was professor of physiology at Heidelberg during 1901–23, and did notable work as director of the Institute for Protein Investigation. He was awarded the Nobel Prize for Medicine in 1910, and died at Heidelberg on July 6, 1927.

No admirer of the work of Pasteur will have forgotten his devoted young assistant Emile Roux (1853–1933), who was so closely connected with the renowned researches on anthrax and rabies. With Alexandre Yersin he discovered the diphtheria toxin, an achievement leading to the discovery of the antitoxin by Emil von Behring in 1890. In 1904, Roux succeeded Duclaux as director of the Institut Pasteur in Paris. He died just before his eightieth birthday, on November 3, 1933, and received a national funeral. Roux had been elected a Foreign Member of the Royal Society in 1913, and received the Copley Medal in 1917.

In conclusion, it seems worth reminding readers that at the anniversary meeting of the Royal Society in November 1853, the president, the Earl of Rosse, informed the Society of a memorial made to the Government bearing some two hundred signatures, including those of many Fellows of the Society, requesting a building for the housing of scientific societies in the metropolis. As a result of this petition, Burlington House was eventually made available to the Royal and other societies, after a site at South Kensington had been refused by men of science on account of its inconvenience.

# GEO-MORPHOLOGY OF $F_2$-REGION IONOSPHERIC STORMS*

By DR. D. F. MARTYN, F.R.S.
Radio Research Board, Australia

DURING the International Polar Year of 1932–33, Appleton and Ingram[1] established a correlation between magnetic storms and temporary reductions of $F_2$-region electron densities at high latitudes. At moderately high latitudes, too (Slough, England), they found that $F_2$-region perturbations were associated with magnetic storms; but here the perturbation was sometimes an increase followed by a decrease of $F_2$-maximum electron density. At equatorial latitudes Berkner and Seaton[2] showed that the normal tendency was for $F_2$-electron densities to increase during magnetic disturbance.

On the basis of these facts, Appleton and Piggott[3] have proposed a system of classification of ionospheric storms which bears a superficial resemblance to that adopted by Birkeland for magnetic storms (for example, 'negative polar storm', 'positive equatorial storm'). On this method of classification certain anomalies appear; for example[3], "Washington (lat. 38·5° N.; long. 77° W.) mostly behaves like an auroral-zone type of station, whereas Burghead (lat. 58° N.; long. 3° W.) and Leningrad (lat. 60° N.; long. 30° E.) are predominantly non-auroral type medium-latitude stations, although all three lie on the same magnetic latitude".

This tentative classification of Appleton and Piggott's is based on the study of noon values of $F_2$-electron densities. Martyn[4] has already pointed out that there is a pronounced diurnal (local time) variation in $F_2$-region parameters during magnetic disturbance. This is found to be big enough to produce inconsistencies if Appleton and Piggott's mode of classification be followed. For example, if midnight instead of noon values be taken, auroral observatories show an increase of $F_2$-electron densities.

A satisfactory method of classification of ionospheric storms almost necessarily presupposes the existence of a plausible theory of their occurrence. Until 1950 it was generally supposed that such storms were due to local impact of particles from the sun, which in high latitudes heated the ionosphere, so reducing electron densities, and in low latitudes contributed to the ionization in some unexplained way. In that year Martyn[5] put forward the hypothesis that disturbances of the $F_2$-region associated with magnetic activity were due in all cases (save possibly 'great' magnetic storms) not to direct particle bombardment, but to the effect of an electrostatic field which spreads over the earth from the intense current systems set up in the auroral zones during all magnetic storms. This field, if it has the magnitude and phase necessary to produce the solar diurnal ($S_D$) current system in the ionosphere, will, it is found, produce the observed perturbations of the $F_2$-region by causing electron (and ion) drifts in accordance with concepts previously advanced[6] to explain tidal phenomena in the ionosphere.

Using this theory as a preliminary hypothesis, an extensive study has been made, during the past three years, of the geo-morphology of $F_2$-ionospheric perturbations associated with magnetic storminess. On this basis it was logical to examine both $S_D$ ($f^0F_2$ and $h'F_2$) and $D_{st}$ ($f^0F_2$ and $h'F_2$) using the methods and terminology developed by Chapman for the corresponding magnetic variations; namely, in the case of the ionospheric $D_{st}$ (disturbance, storm-time), to measure time from the beginning of the sudden or gradual commencement of the corresponding magnetic storm.

Using this procedure the following conclusions have been reached: All major perturbations of the $F_2$-region, save those associated with the relatively small travelling disturbances[7] of unknown origin, are associated with magnetic storms. There is no evidence that such storms travel from the polar zones, with travel-times of the order of hours or days, as has been suggested from time to time. The ionospheric storm at all latitudes begins, either simultaneously with, or in a time less than one hour after, the commencement of the corresponding world-wide magnetic storm. The effect of a magnetic storm on the $F_2$-region depends markedly on the season. In summer, the general tendency of a storm is to lower electron densities, and to raise the heights at which

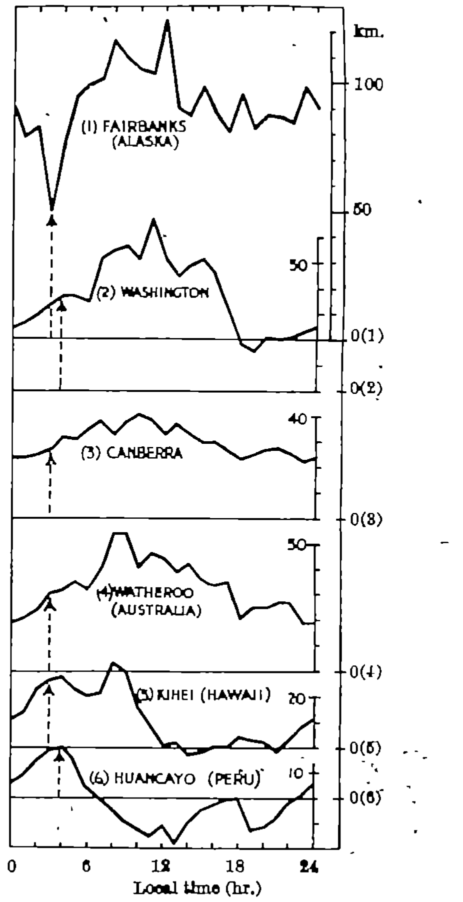

Fig. 1. $S_D(h'F_2)$ average diurnal variation of $h'F_2$ (minimum equivalent height of $F_2$-region) for five International magnetically disturbed days each month minus same variation for five International quiet days each month, for:

(1) Fairbanks, magnetic latitude ($\Phi$) = 64·7° N., April 1944–Dec. 1948.
(2) Washington ($\Phi$ = 50·3° N.), Jan. 1941–June 1948.
(3) Canberra ($\Phi$ = 44·0° S.), March 1937–June 1948.
(4) Watheroo ($\Phi$ = 41·7° S.), Jan. 1944–Dec. 1948.
(5) Kihei ($\Phi$ = 20·9° N.), March 1946–Dec. 1948.
(6) Huancayo ($\Phi$ = 0·6° S.), Jan. 1942–Oct. 1948.

The scale unit is 10 km. in each case.

---

* Substance of papers presented at the recent meetings of the International Scientific Radio Union and of the Mixed Commission on the Ionosphere, at Sydney and Canberra, Australia.

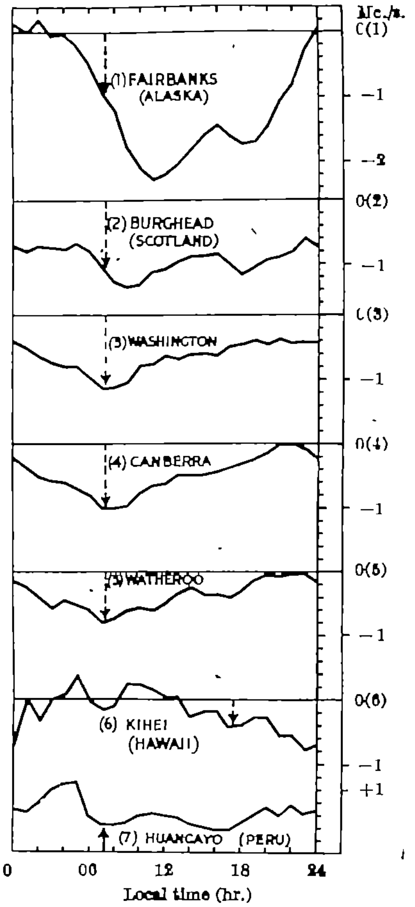

Fig. 2. $S_D(f^{\circ}F_2)$ average diurnal variation of $f^{\circ}F_2$ (critical penetration frequency of $F_2$-region) derived as for $h'F_2$ in Fig. 1 for

(1) Fairbanks (see Fig. 1).
(2) Burghead (Φ = 60·7° N.), Jan. 1943–Dec. 1946.
(3) Washington (see Fig. 1).
(4) Canberra (see Fig. 1).
(5) Watheroo (see Fig. 1).
(6) Kihei (see Fig. 1).
(7) Huancayo (see Fig. 1).

The scale unit is 0·2 megacycle per second in each case.

the maximum densities occur. In winter the densities are reduced in the morning hours, and raised in the afternoon hours.

There is a general tendency for electron densities to be lowered on the average at high latitudes and raised at low latitudes. However, as mentioned above, this statement has to be taken in conjunction with the local time at which such densities are studied. For example, at local midnight, electron densities are above average at high latitudes and below the average in tropical latitudes not too near the magnetic equator (for example, Hawaii, Fig. 2).

The $S_D$ (local time) variation is large and predominantly diurnal (Figs. 1 and 2). Densities are lowest in the mornings and highest in the evenings. The phase of the diurnal variation advances by about four hours as one passes from auroral to equatorial latitudes. At Fairbanks (Alaska) minimum densities (and greatest heights) occur at 11 hr. local time; in equatorial zones at about 07 hr.

There is no evidence that any magnetic storm affects the northern and southern hemispheres differently, when due allowance is made for the seasonal effect described above. The initial effect of any magnetic storm on the $F_2$-region depends markedly on the local time of commencement. If the storm commences at a time when the local $S_D(f^{\circ}F_2)$ curve is at its highest point (say 22 hr. at temperate latitudes), the initial disturbance is a decrease of $f^{\circ}F_2$ (that is, the variation initially follows the $S_D(f^{\circ}F_2)$ curve). If, on the other hand, the storm commences at, say, 10 hr., the initial effect is an increase in $f^{\circ}F_2$. It is suggested that the anomalous result found by Appleton and Piggott[3] for Washington is due to the inclusion of a preponderance of storms commencing in the (local) evening hours in their data. When allowance is made for this bias, Washington is found to have the appropriate characteristics of a temperate-latitude station. This effect is shown for Watheroo in Fig. 3, which exhibits the departure of $f^{\circ}F_2$ from normal during the first three days of magnetic storms which commenced between (*A*) 08 and 11 hr. local time, and (*B*) 20 and 23 hr. local time. (In group *A* are included 17 storms, in *B* 11 storms.) It will be seen that on Appleton and Piggott's classification Watheroo would be classified as a temperate-latitude station on the basis of group *A* storms, and as an auroral station on the basis of group *B* storms.

It appears that $F_2$-region ionospheric storms, like magnetic storms, have a unitary character, and may be regarded as manifestations of a single world-wide phenomenon. The local effects produced by this single phenomenon, which it is suggested is the electrostatic field of the $S_D$ current system, depend markedly on local time and season.

The theoretical (Chapman) diurnal, seasonal and latitude characteristics of the $F_2$-region are normally perturbed by solar tidal electric fields, along lines previously reported[4]. It appears that the phase of the additional electric field present during magnetic storms is such as to increase these perturbations at high latitudes, and to reduce them at low latitudes. This is specially obvious at Huancayo, where the normal daily departures of the $F_2$-region from 'Chapman' behaviour are large, leading to noon

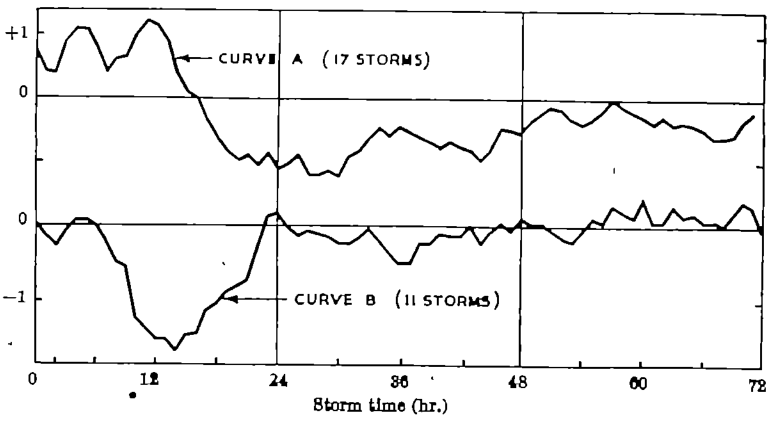

Fig. 3. $D_{st}(f^{\circ}F_2)$ at Watheroo. Hourly values of $f^{\circ}F_2$ for first three days of magnetic storms minus corresponding hourly values for magnetically quiet days, for (*A*) storms commencing between 08 and 11 hr. local time and (*B*) storms commencing between 20 and 23 hr. local time

minima of ionization density, and abnormally rapid pre-dawn reduction of these densities. During magnetic storms these anomalies are removed, and the diurnal variation of $F_2$-region electron densities in the vicinity of the magnetic equator approximates more closely to that anticipated for a simple 'Chapman' region.

This work is published by permission of the Radio Research Board of the Commonwealth Scientific and Industrial Research Organization. I am indebted greatly to Miss B. Hardwick, who has supervised the reduction into appropriate form of ionospheric data from co-operating observatories.

# OBITUARIES

## Mr. H. C. Sampson, C.I.E.

HUGH SAMPSON, whose death at the age of seventy-four occurred on November 29, was an authority on tropical agriculture. His knowledge was gleaned during service in many countries. Born in Simla and educated at Bedford School and the University of Edinburgh, he joined the Transvaal Department of Agriculture in 1903; but after a couple of years he accepted the post of agricultural expert to the Madras Court of Wards. The great renaissance of Indian agriculture was just beginning, and Sampson was one of the first officers to join the newly constituted Indian Agricultural Service. For the next fifteen years he worked in Madras, first as deputy director, with headquarters at Tinevelly, and later as director. His work during this period led to marked improvement in the agricultural methods of the Madras Presidency. He was the first to admit the difficulties that held back progress. Among these were the limitations caused by debt and the system of tenure, and he always, therefore, advocated a cautious approach and preached the necessity for the thorough investigation of natural methods before attempting to discard or alter them. In spite of these hindrances, he was able to effect improvements in the seed supply and modifications in the types of agricultural implements. A notable example was the introduction of a long-stapled American Upland cotton which he introduced from Cambodia after a visit he had made to Indo-China.

In 1923 Sampson resigned from the Indian Agricultural Service and went to Nyasaland as cotton specialist under the Empire Cotton Growing Corporation. He worked there for three years and was successful in laying the foundations of the excellent experimental work that has been carried out in this Protectorate, and in sorting out the mixed cottons that were then grown, initiating modern plant-breeding methods and a proper seed supply.

In 1927 he joined the staff of the Royal Botanic Gardens, Kew, as economic botanist, a post that had been newly created with the connivance of the Empire Marketing Board. He retired from Kew in 1938, but during his term of office he visited the Caribbean Colonies and wrote reports on them for the Empire Marketing Board. He was instrumental in organizing the dispatch of planting material of several new economic crops to various Colonies where prospects seemed suitable. Perhaps the most notable of these was the introduction of tung oil into Nyasaland and Swaziland. His 'magnum opus' was the publication of a *Kew Bulletin* entitled "The Cultivated Crop Plants of the British Empire and the Anglo-Egyptian Sudan", a work that entailed an immense amount of labour and which remains a standard work of reference.

Sampson had a likeable character. His quiet voice, whimsical manner and kindliness endeared him to all his associates. He had the satisfaction in retirement of knowing that the work he had done during those early days in India has had a lasting effect, and one imagines that his memory is still green and respected in the Madras Presidency. G. EVANS

## Dr. J. Henderson Smith

JOHN HENDERSON SMITH, who died on November 28, graduated from Baliol College, Oxford, in 1898, proceeded to Edinburgh, where he took his medical degree in 1903, and then returned to Oxford as Philip Walker Student in pathology. Later, he was appointed bacteriologist to the Lister Institute. Here he did some promising work on immunology; in one of his early investigations, published in 1907, he demonstrated that the concentration of anti-toxin in the blood at any time depends on the route of introduction. Later, in conjunction with Brooks, he studied the influence of the dose of antigen on the output of the antibody and on its time of appearance; the results were published in 1912. All this work was characterized by cleanness and accuracy of experimental technique, and by careful and critical examination of the results; he seemed to have the prospect of a very promising career in his subject.

Then, unfortunately, he was struck down with tuberculosis, and although he made gallant attempts to continue his work he had to give it up; in 1916 he left the Institute.

Henderson Smith refused, however, to abandon scientific work. Fortunately the Rothamsted Experimental Station was beginning to expand and had brought plant diseases within its ambit. Its policy was to bring in young people each well trained in some pure science which he or she could apply to the problems of the Station; in connexion with the new developments, it was desired to find someone well grounded in human or animal pathology who could introduce new ideas and methods into the study of plant pathology. Henderson Smith was attracted to the work; by 1919 he had recovered sufficiently to join the staff, and the healthy surroundings and the devoted care and attention of his wife enabled him to stay out his full term of service with no further serious trouble. He retired on reaching the age limit in 1940.

Henderson Smith's first investigations at Rothamsted were on the growth-rate of fungal hyphæ, but he soon turned to more fundamental studies of the killing of fungus spores by phenol; these proved to be a valuable contribution to the general theory of disinfection. Plant virus diseases were then coming into prominence and he turned over to them: his work soon attracted attention, and following a request from the Imperial Mycological Conference of 1929 that virus diseases should be more fully studied, the Empire Marketing Board provided funds for a research team under his leadership. The work included the nature of the cell inclusions—the so-called X-bodies,—the concomitant bacteria in virus diseases, and the size of the viruses.

When W. B. Brierley left Rothamsted in 1932 to occupy the chair of agricultural botany in the University of Reading, Henderson Smith was appointed to succeed him as head of the Department of Mycology; it continued to expand and to attract able young people, becoming one of the most vigorous at Rothamsted. He served as president of the Association of Applied Biologists, and was also president of the Virus Section of the 1939 International Congress of Microbiology.

'H. S.', as he was always affectionately called, enjoyed much quiet esteem among his colleagues. Under his wife's watchful care he had to be cautious in all matters pertaining to health, but this did not restrict his interests. Like his wife, he was well read; in addition, he was a recognized authority on book plates, of which he was a discriminating collector, and an ardent and competent player of golf and of bridge. He never sought popularity, but his courage and his persistent determination to go on with his work in spite of threatened ill-health won him much respect from those who knew him well.

E. John Russell

## Dr. Franz K. Nagelschmidt

Franz Nagelschmidt, a pioneer of physical medicine, died on October 4 in Manchester. He was born in Berlin on January 29, 1875. He studied medicine, but soon became also interested in physics, for he thought that the many advances in modern experimental physics taking place at the end of the past century could be utilized for medical purposes. He went first to Copenhagen to work with Finsen, the founder of light therapy. He then returned to Berlin and established a light treatment institute at the Charité, where he installed the first X-ray unit for therapeutic purposes in 1903. In 1904, he founded a light treatment institute in Breslau, where he applied radium rays for the first time for treatment. In 1906, he settled in Berlin and founded the Finsen Clinic, of which he was in charge until 1933. Here he developed diathermy—the name was coined by him, and generally adopted, for the creation of heat inside the tissue by external application of electric currents, his best-known discovery. He also designed and introduced an ultra-violet lamp without water cooling. This lamp, the prototype of modern ultra-violet lamps, carried his name for several years. In 1911, he designed an apparatus to produce 'electro-rhythmic current' for electrical vibration treatment. In 1912, he invented the neon lamp, originally for medical purposes.

In 1933, Dr. Nagelschmidt left Germany for Great Britain, where he was immediately made an honorary consultant of physiotherapy at the Jewish hospital in London. In 1934, he had been awarded the "Golden Key" of the American Congress of Physical Therapy for "outstanding service to the science of physical medicine". In 1936, he qualified in Edinburgh as a medical practitioner and settled in Manchester as honorary consultant in physiotherapy at the Jewish hospital. He also founded a private therapeutic institute where he practised physiotherapy and carried out research until about three hours before his death.

Nagelschmidt was a man of many talents and many interests, in art as well as in science. In spite of all his achievements, he was a very modest man. This modesty made him call all the therapeutic establishments installed by him after his teacher Finsen, and this may explain why the scientific world knows the name of Finsen, who first conceived light therapy, much better than the name of Nagelschmidt, who developed it and who added all the other forms of physiotherapy to it. It may also account for the fact that few honours were bestowed on this great man.

W. Roman

We regret to announce the following deaths:

Mr. E. G. Dymond, reader in natural philosophy in the University of Edinburgh, on October 26, aged fifty-two.

Prof. M. G. Evans, F.R.S., professor of physical chemistry in the University of Manchester, on December 25, aged forty-eight.

Prof. A. H. Jameson, emeritus professor of civil engineering in the University of London (King's College), on December 23, aged seventy-eight.

Prof. E. Allison Peers, Gilmour professor of Spanish in the University of Liverpool, and author, under the pseudonym "Bruce Truscot", of books on the functions of universities in present-day Britain, on December 21.

# NEWS and VIEWS

## A Further Cœlacanthid Fish

On December 22, 1938, a fish of Crossopterygian type was taken by trawl-net, at a depth of about 40 fathoms some miles west of East London. The animal was unquestionably alive when caught. It was 1,500 mm. in total length and weighed 127 lb. The colour was a bright metallic blue which faded to brown with preservation. Miss Courtenay-Latimer, curator of the East London Museum, took charge of the catch, and eventually Prof. J. L. B. Smith, now research professor of ichthyology in Rhodes University, Grahamstown, was able to examine it (*Nature*, 143, 455; 1939). Prof. Smith immediately named it *Latimeria chalumnae* gen. et sp. nov., as a tribute to Miss Latimer. This discovery naturally aroused great interest, although, in spite of Miss Latimer's care, much disintegration of parts had occurred. Until then, only fossil records of cœlacanthid fishes, believed to have been extinct for about fifty million years, had been available. Further details of this fish were published in *Nature* (143, 748; 1939) by Prof. Smith.

Now comes a report of a further catch. This second fish was reported as having been caught on December 20 off the island of Anjouan in the Comoro group, two hundred miles west of Madagascar. It was reported to be about 5 ft. long and to weigh about 100 lb. On December 29, the fish was received by Prof. Smith, who had flown to the island to retrieve it and to take it to Rhodes University for further study. Preliminary reports suggest that Prof. Smith is very satisfied with the state of preservation of the fish, and he has named it *Malania anjouanae*, as a tribute to Dr. Malan, the Prime Minister, who had placed an aeroplane at Prof. Smith's disposal. It is of interest to note that the fish was caught in 20 m. of water by an Arab, using a line, and that the islanders claim that two or three such fish are caught each year in the same region and sold in the local market. Further details will be awaited with considerable interest.

## University of Leeds

AT a meeting of the Court of the University of Leeds on December 17, the vice-chancellor, Dr. C. R. Morris, commenting on the difference of opinion as to whether national service should be done before or after embarking on university work, said that while war service in general encourages the development of the intellectual life, there is evidence that national service in peace-time is inimical to it and ability and personality are not developed in the same way. As regards research in universities, he said that, while there may be some research which it would be wrong for universities to undertake, the great increase in the extent of university research in recent years is an advance in the right direction. The national interest requires full use of the highly trained and expert man-power to be found in university departments, and this would require the provision of more money for the maintenance of departments. It has been, he said, a cardinal point of policy with the University of Leeds also to maintain a strong and numerous teaching staff in relation to students, and experience is showing without doubt that this policy is right. Dr. Morris referred to disappointments in progress with halls of residence: more progress has been made with accommodation for women than for men during the past two or three years. The construction of the new refectory and staff house is well advanced and work on the Rayon Building for the Department of Textile Industries is expected to begin in March or April.

## *British Chemical Abstracts*

A QUESTION was asked by Sir W. Wavell Wakefield in the House of Commons on December 16, inquiring whether the Government intends to give any effective support to prevent the termination of the arrangements for the publication of *British Chemical Abstracts*. In reply, Mr. A. E. H. Molson said that the Lord President of the Council was informed of the difficulties that had arisen in regard to the publication of *British Chemical Abstracts*, and that when the question was referred to his predecessor the latter had asked for the advice of the Royal Society. Certain recommendations have recently been received from the Royal Society, designed to ensure the continued publication of these abstracts. These recommendations are at present being examined as a matter of urgency, in consultation with the chemical industry.

## Studies on Primates

THE two recent parts of Vol. 122 of the *Proceedings of the Zoological Society* (Part 1, May; Part 2, August, 1952) contain, *inter alia*, interesting and valuable contributions to our knowledge of the Primates, living and fossil. The former part has a paper by W. C. Osman Hill, Annie Porter and Margaret D. Southwick on the natural history and parasites of the tarsier, *Tarsier carbonarius*, based on studies of two females and one male which were kept alive in the Society's gardens for 692, 957 and 1,043 days, respectively. During these times careful daily records were kept of their behaviour, including the sexual cycle and their reactions to various situations and conditions. The paper also includes an account of their ailments and treatments and a detailed study of their endoparasites. W. C. Osman Hill also describes fully the external features and visceral anatomy of the rare and almost unstudied African olive colobus monkey, *Procolobus verus*. The identity and relationships of a number of the members of the Colobidae are not satisfactorily established, and this study, with its comparative treatment, is a step towards that end. During 1949–51 the British–Kenya Miocene Expedition collected a considerable amount of fossil hominoid material, which is reported upon by Prof. W. E. Le Gros Clark in Part 2. He has been able to add important details concerning five species belonging to the genera *Proconsul* and *Limnopithecus*. The same part also contains an extensive monograph by Dr. A. J. Haddow on the African red-tailed monkey, *Cercopithecus ascanius schmidti*. This is a most meticulous account of the identification, synonymy, biology, ecology and distribution of this species based on the examination of 143 specimens and on countless observations in field and laboratory. It is a more complete study of any African monkey than has been published heretofore, and clears up some of the confusion that exists in this important group of animals.

## Fakes and Forgeries in Museum Objects

IN a paper on "Fakes and Forgeries in Museums" (*Museums Journal*; September 1952), Dr. H. J. Plenderleith, of the Research Laboratory of the British Museum, gives some interesting examples of how the scientific worker can help scholarship in the detection of deception. The methods used are naturally those mainly associated with non-destructive testing. Among many interesting tests, he relates the study of a Greek bronze which could not be sectioned. A coin of known date and composition from Delhi was used as control; it showed certain surface features of decay. When sectioned, however, it revealed a crystalline structure with evidence of inter-crystalline oxidation and even a copper-rich area arising from the secondary reduction of cuprite. Micro-cracks were revealed in the brittle interior and an internal granulated condition at the deepest points of attack. The same tests applied under the base of the Greek bronze yielded results which indicated its genuineness. Such micro conditions would be impossible to fake. The patina of the bronze was, however, olive green in colour, easily detached and showed no foundation of cuprite. These suspicious observations were confirmed by X-ray diffraction. It was therefore clear that, although the bronze was genuine, the patina had been faked.

## Newton's "Principia"

IN the March issue of *Scripta Mathematica*, a quarterly journal devoted to the philosophy, history and expository treatment of mathematics (Yeshiva University, 20th and Northampton Streets, Easton, Pa.), an article is published under the title "A Survey of the Number of Copies of Newton's Principia in the United States, Canada, and Mexico". The survey was inspired by the late Dr. David Eugene Smith and has been carried out by Frederick E. Brasch, a consultant in bibliography, of Stanford University, California. The article directs attention to the Western trend of scientific progress and to the distribution of books—a symbol of this progress. The author rightly maintains that Newton's "Principia" is one of the great books which have laid the foundation of modern mathematics and astronomy and have influenced many aspects of the physical sciences as well as various phases of philosophy and religion. A brief outline of Newton's life is followed by a more detailed study of the "Principia" and its publication, with special reference to the third edition. An interesting section is devoted to the annotated and corrected editions of the "Principia" and includes an account of the so-called folio size copies of the third edition. In the statistical survey with which the article concludes, some seventy-two copies of the "Principia" and their locations are mentioned with appropriate references and comments. The whole forms an interesting and instructive piece of research both from the bibliographical and cultural points of view.

## Plant Growth Regulators

The rapid expansion of our knowledge of the natural plant growth substances and the almost unprecedented success of the practical application of closely related synthetic chemical homologues in agriculture and horticulture have brought with them the usual terminology difficulties, which have unfortunately been aggravated by careless and ambiguous usage, particularly by workers in applied fields of research. Plant physiologists in general have been conscious of the need for a review of this terminology and for authoritative definitions based on modern knowledge and ideas on action and function in the plant. This need has perhaps been felt most strongly in the United States, where an American Society of Plant Physiologists study committee, composed of four leading workers in this field of research (H. B. Tukey, F. W. Went, R. M. Muir and J. van Overbeek), has, for the past two years, been drawing up a new classification to embrace all 'chemical regulators' in plants. They have rightly appreciated that the system should be of world-wide application and have invited comment on their draft scheme from plant physiologists in Great Britain. It is hoped that their final recommendations will be universally acceptable. Their task is no light one since, for example, there are some who might even oppose the use of the term 'regulator' for the many compounds that merely act as cell poisons albeit below the lethal threshold. However, when finally framed and accepted, it should be rigidly applied by all. We must remember, however, that no matter how well it may suit our present needs it cannot be more than an interim classification, and will need further revision as we increase and deepen our knowledge of the exact function and mode of action of these compounds in cell and tissue.

## Water Problems in Dutch Agriculture

A lecture entitled "Lack of Water in a Land of Water", delivered in the international language under the auspices of the British Esperantist Scientific Association, was given by Dr. G. F. Makkink, of the Central Institute for Agricultural Research, Wageningen, on October 21 at University College, London. Dr. Makkink dealt with the problems facing agriculture in the Netherlands as a result of low rainfall combined with the excessive porosity of the soil and also as a result of the ingress of salt water. This latter factor occurs not only by seepage through the dykes but also at the sea-locks and (in dry seasons) by penetration of salt water up the estuaries. He stated, for example, that the sea-locks at Amsterdam admit daily 21 × $10^5$ kgm. of salt into the Zuider Zee, and that during a dry season 24 × $10^7$ kgm. of salt may enter the estuaries daily and not return; during 1949 salt water penetrated 45 km. up the Waal River and threatened the economy of important areas. Dr. Makkink concluded by outlining the ambitious programme of works which is being undertaken not only to reclaim the land out to the arc of the Frisian Islands but also partially to divert the Rhine waters into the Zuider Zee and thus form a huge reservoir of fresh water for agriculture and for use in the battle against the intrusions of sea water.

## National Central Library, London: Report for 1951–52

The thirty-sixth annual report of the executive committee of the National Central Library, London, covers the year ended February 29, 1952 (pp. 22; published by the Library), and records an increase of the Treasury grant-in-aid from £25,000 to £27,250 for 1951–52; of this, £1,000 was to compensate for the discontinuance of the Carnegie United Kingdom Trust's contribution. Contributions from libraries of all types, adult class organizations and individuals increased by 40 per cent to £5,210. The Carnegie United Kingdom Trust has agreed to the merging in the Library's general account of the separate fund for the Union Catalogue of Periodicals in University Libraries. Total issues of books from or through the Library increased from 94,220 during 1950–51 to 98,308; for the Scottish Central Library the corresponding figures are 12,616 and 15,708, and for the Irish Central Library for Students, 11,959 and 12,089. Total applications increased by 9·3 per cent, and 69·37 per cent were dealt with successfully, compared with 65·3 per cent during 1950–51. Issues to university libraries increased by 26·09 per cent, and those to outlier libraries, libraries of government departments, industrial and research organizations, and educational and cultural bodies also increased. University libraries lent 38,962 volumes under the national system. Loans made to foreign libraries remained at a high level (1,589 books to thirty-seven countries); but books borrowed from foreign libraries increased from 584 to 885 books from eighteen countries. The report refers to the need for extra funds for union cataloguing and the development of the outlier library system, as well as to progress in the union cataloguing of Russian books and periodicals available in Britain, and to the increased activities of the British National Book Centre in re-allocating 'unwanted' books and periodicals between British libraries and between libraries in Britain and those abroad. The reconstructed building of the National Central Library was opened by the Earl of Elgin in June 1952.

## Physics of Particle-Size Analysis: Conference in Nottingham

The Institute of Physics is arranging a conference on "The Physics of Particle-Size Analysis", to be held in the University of Nottingham during April 6–9, 1954. It is anticipated that the various sessions will cover not only such fundamental physical processes as the fluid dynamics and the optics of particles and systems of particles, but also accounts of other phenomena encountered in particle-size analysis such as the aggregation and dispersion of particles in a fluid. Arrangements will be made also for a discussion on automatic methods of counting and sizing, to which great attention is being given at the present time. Although the conference will be primarily concerned with the physical principles of particle-size analysis, the development of new instruments and their use will receive attention, particular interest being attached to the systematic comparison of different methods of particle-size analysis. Papers describing original work are invited for reading and discussion at the conference, and synopses of such contributions should be sent before February 3 to the honorary secretary of the conference, Mr. R. L. Brown, at the Institute of Physics, 47 Belgrave Square, London, S.W.1.

### Static Electrification: Conference in London

THE Institute of Physics has arranged a conference on static electrification, which will be held at Bedford College, London, during March 25–27. Prof. F. A. Vick, of the University College of North Staffordshire, Stoke-on-Trent, will give the opening lecture, and the other sessions will each take the form of an introductory survey, followed by specialized papers and discussion. The introductory surveys will be given by Dr. P. S. Henry (general principles of the generation and dissipation of static electricity), Mr. E. S. Shire (electrostatic machines) and Mr. H. W. Swann (harmful static electrification). The more specialized papers will be available as pre-prints to those attending the conference, and the proceedings of the conference will later be published by the Institute. Further information can be obtained from the conference secretary, Mr. N. Clarke, at the Institute of Physics, 47 Belgrave Square, London, S.W.1.

### University of London

THE title of reader in the University of London has been conferred on the following: Dr. N. A. Barnicot, in physical anthropology, in respect of the post held by him at University College; and Dr. J. M. Coulson, in chemical engineering, in respect of the post held by him at the Imperial College of Science and Technology. The degree of D.Sc. has been conferred on Mr. Harold Barnes.

### Announcements

M. JULES BAILLAUD, honorary director of the Pic du Midi Observatory and honorary astronomer of the Paris Observatory, has been elected a member of the Astronomy Section of the Paris Academy of Sciences in succession to the late B. Lyot.

ON the occasion of his retirement from the post of research professor in agriculture in the University of Sydney, Prof. W. L. Waterhouse has been elected an honorary life member of the Royal Agricultural Society of New South Wales, in recognition of his outstanding investigations on cereals.

DR. F. A. FOX, formerly deputy director of the British Welding Research Association, has been appointed superintending scientist in charge of the Chemical and Physical Research Laboratories, Australian Government Department of Supply, Maribyrong, Melbourne.

THE following have been appointed to senior lectureships in the University of Sheffield: Dr. J. S. D. Bacon (biochemistry) and D. R. Wood (pharmacology).

MR. P. ARTHUR WELLS, deputy secretary of the Royal Sanitary Institute, has been appointed secretary of the Institute in succession to Dr. J. W. Dudley Robinson, who has recently retired (see *Nature*, October 25, 1952, p. 693). Mr. Wells also becomes secretary of the Royal Sanitary Institute and Sanitary Inspectors Examination Joint Board and secretary of the National Nursery Examination Board. Previously he has been director of education to the International Wool Secretariat and general secretary of the Society of Dyers and Colourists.

THE Scottish Branch of the Science Masters' Association will hold its annual meeting at the Heriot-Watt College, Edinburgh, during April 7–10, with the principal of the College, Dr. H. B. Nisbet, as president. Other speakers will include Prof. G. F. Marrian, Dr. Neil Campbell, Dr. D. B. McIntyre, R. M. Sillitto, N. G. Matthews, G. Barclay and W. W. Fulton. Visits will be arranged to various places of scientific interest in the neighbourhood, and there will be exhibitions by members of the Association, publishers and manufacturers of scientific apparatus. Further details can be obtained from the organizing secretary, J. Turpie, Trinity Academy, Edinburgh 6.

A JOINT meeting of the Hospital Physicists' Association and the Industrial Radiology Group of the Institute of Physics is to be held at the Royal Institution, Albemarle Street, London, S.W.1, on January 16, at 7 p.m., and January 17, at 9.30 a.m., to discuss "Radiation Protection". Particulars can be obtained from the joint honorary secretary of the Industrial Radiology Group of the Institute of Physics, B. R. Byrne, Railway Executive, Research Department, Ashford Works, Kent.

THE Aslib Aeronautical Group of technical librarians and information officers serving the aircraft industry will hold its second annual conference at the College of Aeronautics, Cranfield, during March 27–30. Technicians and librarians from Europe, America and the British Commonwealth will be contributing papers, and all who are interested in promoting the efficient exchange of aeronautical information are welcome to attend. Further information can be obtained from the secretary of the Group, Mr. C. W. Cleverdon, College of Aeronautics, Cranfield, Bletchley, Bucks.

A DAVID ANDERSON-BERRY Silver-Gilt Medal and a sum of £100 is being offered by the Royal Society of Edinburgh to the person who, in the opinion of the Council, has recently produced the best work, published or unpublished, on the therapeutical effect of X-rays on human diseases. Applications, which should be accompanied by relevant papers on the work, must be sent to the General Secretary, Royal Society of Edinburgh, 22 George Street, Edinburgh 2, before March 31.

THE Medical Research Council is offering a number of fellowships in clinical research, tenable in the United Kingdom during the academic year 1953–54, which are open to suitably qualified medical graduates who desire to prepare themselves for a career in clinical research. The fellowships will be awarded for one year in the first instance, renewable annually up to a maximum of three years, and will carry a stipend of £850 a year, with annual increments of £75. Applications must be sponsored in each case by the head of the appropriate department in the candidate's university or medical school. Application forms can be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, London, S.W.1, to whom they must be returned not later than March 1.

# TEACHING OF ACOUSTICS

A DISCUSSION on the teaching of acoustics, under the joint auspices of the Acoustics Group of the Physical Society and the Education Group of the Institute of Physics, was held at the offices of the Institute in London on November 19, 1952, Mr. W. West, chairman of the former Group, presiding.

Dr. R. W. B. Stephens, in introducing the subject, said that acoustics has for long been somewhat neglected in schools and universities of Great Britain. This state of affairs is unfortunate; for the study of vibrations is fundamental to the whole of physics, and acoustics is probably the best vehicle for illustrating wave motion, as it provides a means of actually observing the nature of the motion as distinct from inferring it—for example, as in the case of light. In schools, a reason for the somewhat scanty attention to the subject most probably arises from the very crowded syllabus and from the fact that, viewed from the aspect of passing the General Certificate Examination (ordinary level), it has a limited value. It has been the practice for some time for only one or two questions to be set, and these in general have been modifications on a very restricted theme, which must have brought about a tendency to limit the teaching of the subject to the consideration of the few types of questions which are likely to occur. It is evident, thought Dr. Stephens, that examiners cannot escape criticism, for in the wording of questions more attention might be directed to the physics of a problem rather than making it a problem in algebra and a substitution in a formula.

In college and university there is the tendency to restrict the teaching of acoustics and regard it perhaps somewhat as an applied subject which by modern standards puts it on a lower academic plane, compared with theoretical nuclear physics. In point of fact, however, modern acoustical theory uses all the tools of mathematical physics. The treatment of acoustics as a Cinderella subject is somewhat unfortunate, as apart from academic considerations (and these are widespread, for basic acoustic theory and techniques permeate into the fields of aeronautics, applied mechanics, light electrical engineering, rheology, etc.) there is also the impact of the subject on modern everyday life which is made increasingly evident—to mention a few examples—by the problems arising from noise and vibration in aircraft, flats, factories, etc.; design of concert halls; development of electronic musical instruments, etc.

Dr. Stephens then gave the results of a questionnaire on this subject circulated to universities by the Acoustics Group. It appears that most universities think that a course is desirable, and most do give their students a specialized course of ten to fifteen lectures. There are seven postgraduate courses in all, and a number have facilities for research.

Mr. E. Nightingale, as a schoolmaster of long experience, admitted that in schools the subject does not receive anything like the attention it deserves. This is due partly to the greatly expanding physics syllabus, and partly to the fact that many teachers are afraid of the subject unless they are musically minded. Also, one must face the fact that, in the early stages, the subject does not lend itself to practical work mainly owing to the necessity for quiet in many of the experiments. This leads to the complete exclusion of the subject at this stage and to an inadequate and sketchy treatment in the sixth form. In the old days, when 'heat, light and sound' was an examination subject for the School Certificate, acoustics received far more adequate treatment than at present.

The teaching of acoustics, continued Mr. Nightingale, can be begun informally quite early by means of a useful talk on the meaning of frequency, overtone and harmonic, illustrated by simple experiments on the piano and the violin or 'cello. There is also great scope for a series of formal lessons illustrated by simple experiments of the 'sealing wax and string' type. These can give a far better training in basic physics than any number of spectacular experiments using boxed-up apparatus of the push-button type. The mathematical theory of wave motion must be left largely to the sixth form, when the necessary mathematical equipment should be available. But the fundamental ideas of frequency, period, wavelength, the equation $V = n\lambda$, the simple treatment of resonance and beats, the dependence of quality on overtones, can all be taught in the pre-Certificate course.

Mr. Nightingale then illustrated some simple experiments within the capabilities of a secondary school and showed—on a tape record—what could be done on a piano.

Dr. E. G. Richardson pointed out that acoustics is now firmly established as a subject for special study and research in four British universities, mainly with the aid of the University Grants Committee and of certain government institutions, which are anxious to have available personnel trained in the subject. Though this is good so far as it goes, the facilities in acoustics compare unfavourably with some other countries. In both the United States and Germany there are university departments or whole institutes devoted to this subject. (In the United States a number are called applied physics, but they are really acoustics plus electronics or radio waves, and the same combinations are found in Germany.) In some other European countries there are acoustics departments attached usually to technological universities, but in other countries acoustical work is done in government institutes with but a slender attachment or none to a university faculty.

Four types of students in universities require instruction in sound. Physicists certainly do, but more restricted courses are also given to architects, electrical engineers and musicians. Until he gets into the special honours school, the physics student gets little sound, but in fifteen lectures enough can be done to prepare the student for a post in industry or to start postgraduate research. There is no doubt, said Dr. Richardson, that nowadays a student could scarcely undertake experimental research in sound without a good working knowledge of electronics. In the days of Rayleigh and Lamb, hydrodynamics was the handmaid of acoustics. The pendulum has swung too far in the direction of making acoustics a branch of radio communication, which Dr. Richardson thinks is undesirable except for electrical engineers.

In the general discussion that followed, Mr. W. A. Mercer gave details of courses he is giving to honours physicists in the University of Southampton; he divides the subject into classical and modern acoustics, devoting more time to the latter. Drs. H.

R 299

Lowry and W. H. George spoke of the difficulties of teaching sound to music students, and the latter spoke also of the new M.Sc. course in the University of London, while Mr. S. R. Humby amplified previous speakers' comments on the teaching of wave motion to sixth-form schoolboys. At the conclusion of the discussion, experiments suitable for demonstrations were inspected.

# PHYSIOLOGY OF THE HOST–PARASITE RELATIONSHIP IN FUNGI AND BACTERIA

THE annual plant-pathological meeting of the British Mycological Society, which was held on October 17 in the Physics Lecture Theatre of Birkbeck College, London, took the form of a symposium on the physiological relationship of host plant and parasite. Nine papers were read dealing with various aspects of this wide problem.

Prof. W. Brown (Imperial College of Science and Technology, London), who introduced the discussion, dealt primarily with the type of facultative parasite which is relatively non-specialized and which characteristically brings about a distinct rotting and killing of the host tissue. This is probably the simplest of all types and the one most open to investigation, as the effects arising are localized to the neighbourhood of the parasite and can, to a large extent, be reproduced *in vitro*. It is logical, therefore, to begin by attempting to elucidate the mechanism of the more generalized parasites and to proceed from there to the more specialized types, as illustrated by the obligate but also by many facultative parasites.

Events which take place before the parasite has penetrated the outer wall of the host and the act of penetration itself are of considerable interest and practical importance, and the physiology of these stages could be further clarified. It is, however, when entry has taken place that the most interesting relationships develop. The tissue-destroying agents are metabolites excreted by the parasites, and, though it is not safe to ignore any of these, chief attention has been paid to pectolytic enzymes and organic acids. With some fungi, such as *Botrytis cinerea*, pectin-dissolving enzymes appear to be the sole agents. The study of this parasite and of others which act similarly, for example, *Pythium* spp., *Bacterium aroideae*, has thus become largely enzymological, with special reference to the conditions which govern enzyme secretion, and to the detailed differences in behaviour (such as selective action on various cell walls and constituents of cell walls, relation to *p*H and to various retarding and inhibiting agents, etc.) which are shown by the pectolytic enzyme systems of various parasites and saprophytes.

The part played by contact stimulation (thigmotropism) in the physiology of obligate parasites was discussed by Dr. S. Dickinson (Cambridge). It has been shown that the latter (rusts, powdery and downy mildews) respond to a contact stimulus by division of their nuclei, such stimulation being given on contact with stomatal guard cells, cuticle of epidermis, mesophyll wall and perhaps even outer layer of the protoplast. Thigmotropism is therefore a primary factor in obligate parasitism, a view which accords with recent American work in this field. It is suggested that this particular response to contact stimulation is the chief distinguishing characteristic between obligate and facultative parasites, and that in other ways, for example nutrition, they do not materially differ.

Dr. S. E. Jacobs and Mr. A. H. Dadd (Imperial College of Science and Technology, London), dealing with the leafy-gall organism (*Corynebacterium fascians*) and its behaviour on a wide range of host plants, showed that diffusible antibiotic substances are present in seeds of some of these host species. An inverse relation was discovered between percentage of seedling infection and the degree of inhibition of the bacterium brought about by exudates from seed. The inhibitory substance, when present, could be removed by soaking the seeds, but this treatment did not lead to increased infection; it had the reverse effect, possibly because of simultaneous removal of diffusible nutrients. Extracts of crushed seeds, especially after being allowed to undergo a certain amount of bacterial decomposition, stimulated growth of the parasite and increased the pathogenicity of all pathogenic strains, but failed to stimulate non-pathogenic strains to attack the host. These effects were likewise obtained by use of various chemical substances.

Mr. J. E. Crosse (East Malling Research Station) outlined the annual cycle of the bacterial canker disease of cherry caused by *Pseudomonas mors-prunorum*, an over-wintering canker phase on the bark alternating with an over-summering leaf-spot phase. Infections of the bark take place in the autumn and mainly through the scar-wounds which arise at leaf-fall. Experiments with concentrated inocula gave a much higher percentage infection of a resistant as compared with a susceptible variety than was normally encountered in the field. This disparity was traced to the fact that in the autumn the parasite was more abundant on the leaves of the susceptible than of the resistant variety. As the infective bacteria are washed down by rain, the concentration of inoculum in the infection drops is likely to be higher in the susceptible variety.

A series of inoculation experiments, carried out with a range of concentrations of inoculum and at four dates during the leaf-fall period, showed clearly that the concentration of inoculum necessary to give 50 per cent infection was higher with the resistant variety. Resistance to canker under field conditions was thus a compound of two factors, a lower prevalence of the parasite on the leaf surface and a higher threshold concentration of inoculum required for infection. As a result, the conditions necessary for successful invasion were less often realized at ports of entry on the resistant variety. Infectivity of leaf scars had also been shown to vary with the date at which inoculum was applied; but the precise relationship had not yet been worked out.

Dr. P. S. Nutman (Rothamsted Experimental Station) discussed the interaction between leguminous plants, in particular clover, and strains of the nodule-forming organism. 'Effective' or symbiotic strains produced a limited number of nodules which were large and which fixed nitrogen; 'ineffective' or parasitic strains gave nodules in abundance, but these remained small because of early degeneration of their growing-points and they did not fix nitrogen. Incompatibility between the clover plant and a bacterial strain which was normally effective was also shown in certain nutritive states of the former, and the same appearances resulted as with an atory. He took samples under water in the infralittoral and littoral zones during high water, by diving, "using nothing but glasses, flippers and a belt with pieces of lead fixed to it". Eight weeds were chosen, and one sample of *Gelidium corneum* yielded the astonishing number of 2,818 animals per gram of dry weed, including 600 Nematodes and 1,864 specimens of *Lasæa rubra*. Observations under water, using a modified frogman apparatus, were also made by Mr. R. Bainbridge, who describes the swimming habits of *Calanus* and *Sagitta*.

The necessity to control the bacterial contamination of mould-free phytoplankton cultures led Mr. C. P. Spencer to experiment with the antibiotics penicillin and streptomycin, the former being the more effective in keeping the culture pure. Miss B. Ross studied the changes in chemical composition at various ages of *Himanthalia elongata*, and found that any estimate of the chemical composition at different seasons should be correlated with the size of the vegetative buttons and thongs. Cultures of sixteen species of the smaller marine algæ, including seven flagellates, were prepared by Mr. R. W. Butcher, whose paper is illustrated by coloured figures of all the species. Finally, the first number of Vol. 31 concludes with an interesting account by Dr. D. P. Wilson of the aquarium and sea-water circulatory system at the Plymouth Laboratory.

In the second number, Dr. H. G. Vevers describes improvements in his apparatus for photographing the sea floor, whereby the camera is set at 1 m. from the ground and records an area of 50 cm. × 50 cm., thus producing better definition. As the result of his surveys, Dr. Vevers estimates that near Looe there is a population of *Ophiothrix fragilis* at least two miles long and half a mile broad, at a density of 392,000 per acre. North-west of the Eddystone the population is even greater and reaches 1·3 million per acre. In both cases, tidal streams probably bring suspended food to the crowded beds, and the scavenging work of these brittle stars, whether of detritus or of sinking matter, must be considerable.

Dr. R. B. Pike has worked on the biology of the prawn *Pandalus bonnieri*, which is a diœcious species living in deep water. Breeding occurs from the end of October for from six to eight weeks, and the young leave the berried female from February to April in the following year, metamorphosing in June. Sexual maturity is reached in eighteen months. The maximum life-span is four years; but few live beyond three years in the Clyde area.

Dr. J. S. Alexandrowicz studied the muscle receptor organs in the Paguridæ, and Mr. Graham Hoyle the response mechanism in the Ascidians, *Phallusia mammillata* and *Ascidiella aspersa*. Prof. J. E. Harris has kept records of the breeding condition of dogfish supplied to the University of Bristol from the Ilfracombe area, and concludes that spawning starts in November and continues until July. A Fulbright scholar from Miami, Mr. R. F. Hutton, has named a cercaria from the cockle, *Cercaria fulbrighti*, and gives a full description of it and other parasites from this lamellibranch.

To the biological indicators of water movements in the English Channel (*Sagitta* and *Muggiæa* spp.), Dr. L. H. N. Cooper suggests adding the boar fish, *Capros aper* (L.), the occurrence of which coincides with that of *Muggiæa kochi*, indicating movement of water from the south-west area of the continental slope towards Plymouth, after a period of strong south-west winds succeeded by calm weather. Hydrographical observations are recorded by Dr. W. R. G. Atkins and Miss P. Jenkins, and on the reaction of marine animals to ultra-violet light in conjunction with echo sounders by R. E. Craig and I. G. Baxter, who hope that further work will produce results of practical importance to the fishing industry.

In their first paper in a series on the vitamin A and carotenoid content of invertebrates, Mr. L. R. Fisher and Drs. S. K. Kon and S. Y. Thompson describe an investigation of the various Crustacea from the British coasts, particularly the Euphausiids, *Meganyctiphanes norvegica* and *Euphausia superba*, the krill upon which some whales feed. These contained large quantities of vitamin A, 90 per cent of which was in their large eyes, together with a high proportion of their astaxanthin. No carotene was present. The vitamin A concentration was lower in decapods, absent in the copepod *Calanus finmarchicus*, amphipods, isopods and *Cladocera*. By consuming krill, a baleen whale may take in one ton of vitamin A, to be stored in the liver, which would yield about 2,000,000 I.U.

The volume ends with the report of the Council of the Marine Biological Association. It is pleasant to note that for the first time the Association will be able to have a vessel specially built as a research ship. Membership has increased by 47 to 659.

N. B. Eales

## PATTERNS OF SPRING MIGRATION

IN 1950 and 1951 the British bird observatories exchanged information about the occurrences of selected species of birds. A study of this collated information by R. K. Cornwallis appears to throw some light on the pattern of migration to and through the British Isles in spring (*British Birds*, 45, No. 9; September 1952).

The simple conception of this pattern of spring migration is one of a south-to-north movement. The birds, it is assumed, enter England at points along the south coast and proceed northwards until they either reach their breeding-grounds in Britain, or, if they do not remain to breed, strike north-west to Iceland or north-east to Scandinavia from our northern coasts. This is often assumed in ornithological writings to be what happens, though the subject is a neglected one.

Not all the facts, however, appear to fit this simple pattern. For example, certain birds which breed in Scandinavia and occur in Britain both as summer residents and as passage migrants were recorded on spring migration in 1950 in greater numbers at the more northerly bird observatories, the numbers decreasing regularly with each more southerly observatory in turn (pied flycatcher, garden warbler, lesser whitethroat, common redstart).

It is common, too, when waves of birds are recorded at the east-coast observatories, for these to occur on approximately the same date at all of them and not progressively later at the more northerly stations (redstarts, pied flycatchers, fieldfares and ring ouzels). Moreover, the greatest numbers of some birds are often observed, particularly at east-coast stations, on dates when British breeding birds of the same species have already started nesting, even when the breeding-ground lies farther north than the observatory.

A fourth fact is that at Gibraltar Point the direction of diurnal migration in the spring, as well as in the autumn, is almost invariably to the south-west. At Cley it is from east to west. In north Lincolnshire it is more orthodox, being north-west along the south bank of the Humber, but at Spurn both northward and southward movements are seen.

The most likely explanation of these facts seem to be that, as well as receiving migrants in accordance with the simple south–north pattern, the British Isles also receive "drift-migrants" which, aiming for their Scandinavian breeding-grounds, are drifted westwards across the North Sea by the wind.

It is likely that drift of this kind affects nocturnal migrants much more than it does diurnal ones, for they, presumably, must rely for navigation principally on "preferred direction" and not on coastal and other "guiding-lines", and are therefore more likely to be sent off-course by the invisible forces of wind-drift. The directions of diurnal migration at Cley and Gibraltar Point, however, seem to indicate that some diurnal migrants are also subject to drift of the same kind.

Drift-migration of this type explains the coincidence of dates on which "waves" of birds are recorded as reaching the east coast, and also explains the movements after British breeding birds are already nesting; these later movements are composed of quite different, probably Scandinavian, breeding populations.

T. H. HAWKINS

# AFFINITY: A NEW GENETIC PHENOMENON IN THE HOUSE MOUSE

## Evidence from Distant Crosses

IT is generally assumed that at the first meiotic division the orientation of each bivalent towards the poles of the cell is at random, and consequently that (apart from viability disturbances) genetic linkage is the basis of all departures from Mendel's Law of Independent Assortment. Exceptions to random orientation are known in, for example, *Sciara*[1,2], certain scale insects[3], the Ascomycete *Bombardia lunata*[4], and *Drosophila melanogaster*[5]. Analogous phenomena in Heteroptera have been described and discussed by Dr. C. D. Darlington[6].

In the last two cases, the region of the chromosome responsible for the preferential orientation was shown to be the neighbourhood of the centromere, as might in general be expected, since it is the centromere which normally directs the orientation and movement of the chromosome on the spindle.

If the respective centromeres of more than one chromosome simultaneously show non-random segregation, the loci lying on *different* chromosomes may appear to belong to the same linkage group. The strength of the apparent linkages will depend both on the degree of preferential orientation of the centromeres and on the strength of the true linkages between the loci concerned and their centromeres. Such quasi-linkages will not show the type of arithmetical regularities which characterize true linkage and which reflect the linear order of the linked loci on the same chromosome.

The purpose of this communication is to suggest an interpretation along these lines of anomalous segregation ratios which were obtained by various workers many years ago from distant crosses in the mouse. It is hoped that the hypothesis advanced here will, if confirmed, be of some genetic and evolutionary interest.

The main body of data to be considered resulted from a cross performed by Gates[7] between a male 'Japanese' waltzer (a domesticated variety of *Mus bactrianus*) and a female European laboratory mouse (*Mus musculus*). The phenotypic frequencies in the backcross progeny departed strikingly from Mendelian expectations, as can be seen from the accompanying table. In addition to the marked loci shown, segregation also occurred at the pink-eye locus. But since it made no contribution to the statistical disturbance, the data are presented here after combining the pink-eyed with the non-pink-eyed classes.

PHENOTYPIC RATIOS DERIVED BY GATES FROM AN *M. musculus* × *M. bactrianus* CROSS

First cross:
$♀\frac{pdb{+}{+}}{pdb{+}{+}} \times ♂\frac{{+}{+}{+}sv}{{+}{+}{+}sv}$
Backcross
$F_1♀♀\frac{pdb{+}{+}}{{+}{+}{+}sv} \times F_1♂♂\frac{pdbsv}{{+}dbsv}$

| Backcross progeny | | | | Comparison of observation with expectation calculated on the basis of 'polar' affinity. Complementary genotypes added | |
|---|---|---|---|---|---|
| | | | | Observed | Expected |
| ++*sv* | 117 | *db*++ | 86 | 203 | 199·7 |
| ++*s*+ | 77 | *db*+*v* | 85 | 162 | 176·6 |
| +++*v* | 85 | *dbs*+ | 83 | 168 | 172·8 |
| ++++ | 81 | *dbsv* | 88 | 169 | 162·9 |
| +*bsv* | 77 | *d*+++ | 90 | 167 | 167·0 |
| +*bs*+ | 73 | *d*++*v* | 86 | 159 | 147·7 |
| +*b*+*v* | 79 | *d*+*s*+ | 67 | 146 | 144·5 |
| +*b*++ | 59 | *d*+*sv* | 56 | 115 | 127·8 |
| | | | | 1,289 | 1,289·0 |

*d* = dilute, *b* = brown, *s* = pied, *v* = waltzing

The fit to expectation is very poor. $\chi^2_{(15)}$ is 36·170, and if we eliminate the eight degrees of freedom relating to the equivalence of complementary genotypes, we have $\chi^2_{(7)} = 26{\cdot}432$ ($P < 0{\cdot}001$). Gates noted that the ratios were disturbed and also that the single-factor ratios were good. He directed attention to the marked excess of the *bactrianus* combination of characters, and as an interpretation he postulated an "association system"—"a definite tendency on the part of the chromosomes to associate together according to parental grouping, thus distorting the theoretical proportions". His meaning is not entirely clear for the following reasons: (1) the parental chromosomes no longer exist as such after crossing-over; each chromosome enters a gamete as a patchwork of material derived from both parents; (2) he remarks, "The chromosomes of the female parent, as representative of the fancy mouse, do not seem to group together as strongly as those of the Japanese parent . . .". This casts doubt on whether he intended to refer to meiotic phenomena at all; and (3) earlier work to which he refers as exemplifying "association systems" in fact relates to superior viability of non-recombinant gametes in species hybrids, and not to the mode of gamete formation.

Gates's phrase 'association system' did, however, suggest the present hypothesis, which may, in fact, be no more than a development of his intended meaning. It is that, at the first meiotic division in the hybrid, *musculus* centromeres tend to go to one pole and *bactrianus* centromeres to the other. Sir Ronald Fisher has suggested to me that the term 'affinity' be adopted for this phenomenon. It could result from an attraction of centromeres of like origin either for each other (which I shall term 'mutual affinity'), or for some polar element of the cell ('polar affinity').

On the hypothesis of 'polar affinity', the best-fitting assumptions are that the segregation of *d* is completely polarized, and that *b*, *s* and *v* are polarized with intensities, calculable from their respective frequencies of segregating to the same pole as *d*, namely, 54·46 per cent, 53·61 per cent and 53·06 per cent. On the basis of other work[8], these loci have been assigned to separate linkage groups, and their mutual relations in Gates's data are incompatible with true linkage.

The expected numbers calculated on these assumptions are shown in the table. $\chi^2$ measuring goodness of fit is 14·013 and has eleven degrees of freedom, four having been used in the estimation of four parameters. If we eliminate the eight degrees of freedom corresponding to the equivalence of complementary genotypes, we have $\chi^2_{(3)} = 5{\cdot}274$ $(0{\cdot}2 > P > 0{\cdot}1)$. Hence the fit is judged to be satisfactory. An even closer concordance between observation and expectation can be attained if the affinity is assumed to be of the 'mutual' type. Indeed, a simplified model of mutual affinity can be devised which will reduce the $\chi^2_{(7)}$ of 26·432 $(P < 0{\cdot}001)$ to a $\chi^2_{(6)}$ of 2·406 $(P > 0{\cdot}8)$.

There are two other bodies of data derived from *M. musculus* × *M. bactrianus* crosses which are suitable for testing this hypothesis[9,10]. In both, the wild variety of *M. bactrianus* was used. Since Gates's data indicate that *d* is very close to its own centromere, the most relevant and informative quantities are the frequencies of recombination between *d* and the other segregating genes.

It turns out that the segregations of *d* with *a* and with sex are compatible with independent assortment; but, as expected, apparent linkage between *d* and *b* appears in these data too. The actual recombination frequencies, however, exhibit some remarkable incongruities. Female hybrids of the *M. musculus* × wild *M. bactrianus* cross show significantly more recombination (53·3 ± 2·3 per cent, from Green's data) both than female *M. musculus* × Japanese waltzer hybrids (45·5 ± 1·4 per cent, from Gates's data), and than their male *M. musculus* × wild *M. bactrianus* counterparts (40·8 ± 2·4 per cent, from Little's and Green's data combined). However, sex differences in crossing-over are not unusual in the mouse, and it is a commonplace that chiasma formation is suppressed in distant crosses to a greater or less extent according to the degree of genetic disparity between the parental forms. The Japanese waltzer has been split off from the wild form for many centuries, a period of time in which considerable genetic divergence between the two groups could occur.

Dr. C. D. Darlington has suggested to me a possible variant interpretation of these data according to which the Asiatic and European forms differ by a reciprocal translocation. But it is likely that such an interchange would be associated with substantially reduced fertility, at least in the female hybrids, in contrast with the exceptionally high fertility reported by both Gates and Green.

It is intended to publish in due course a full account of the theoretical deductions from the *M. musculus* × *M. bactrianus* crosses, together with a discussion of the evolutionary significance and possible physical basis of the phenomenon. In spite of repeated efforts, it has not yet been possible to obtain stocks from which to produce hybrid material suitable for applying cytological and further genetic tests to this theory.

I am indebted to many people for criticisms and suggestions, especially to Dr. A. R. G. Owen and Mr. N. T. J. Bailey for statistical help and advice, to Sir Ronald Fisher, Prof. J. B. S. Haldane and Dr. C. D. Darlington for helpful discussions, and to Dr. E. B. Ford for his continual interest and encouragement, and for his strenuous attempts, as yet unhappily unrewarded, to obtain live specimens of *M. bactrianus* for me. I am in receipt of a research training grant from the Medical Research Council, and I wish also to express my gratitude to the Agricultural Research Council for the provision of facilities.

## Evidence from within Laboratory Stocks

OVER a period of a few years, I have observed, in data produced for other purposes, an association between *W* (dominant pied) on chromosome III, and *Sd* and *fi* (Danforth's short tail and fidget) on chromosome V of the house mouse. Sir Ronald Fisher, on receiving privately from Mr. Donald Michie, of the Genetics Laboratory, Oxford, his interpretation of the findings of Gates[1] and others, realized that here might lie an explanation of this association, and proposed the term 'affinity' for the phenomenon.

Affinity, or an effective attraction between like centromeres, is proposed by Michie as producing the quasi-linkages observed by Gates and others in backcross progeny from the $F_1$ of crosses between two sub-species of *Mus*. (It is not intended to discuss here whether this attraction is direct—between centromeres only, or indirect—between centromeres and differentiated poles of the dividing cell.) That such an attraction of centromeres might also operate within a colony of a species (namely, *Mus musculus*) now became apparent to Sir Ronald Fisher and myself. The principle of affinity within a species, if it can be established as of more or less general application among plants and animals, has some important aspects. One is that, without the use of sub-specific hybrids, which has several disadvantages, it facilitates both identification of centromere markers and calculation of the positions of centromeres on their chromosomes. Affinity observable within a species has, also, an evolutionary significance.

In order to establish this principle, I have planned a method of manipulating the genetic material available, involving chromosomes III and V, in order to show various kinds of segregation of their centromeres, and in order to calculate the position of the centromere on chromosome V. I have also searched for and found, from experiments designed for other purposes, data which appear to show segregation of centromeres in other chromosomes.

A satisfactory demonstration of affinity, from unprepared material, is not easily made. There are several reasons for this. One is the expected disappearance of quasi-linkage on inbreeding, or on using stocks of which the centromere genotype has not been tested or fixed by inbreeding. Another is the difficulty of distinguishing not only quasi-linkage of high recombination value from independence, but also of distinguishing these two from reversal of the linkage, which can theoretically occur; from unprepared material it is not always possible to calculate which of these kinds of quasi-linkage will occur, or to calculate exactly their expected frequencies. Reversal can be defined (in the terms of real linkage) as the segregation in one linkage phase of centromere markers known to be ancestrally in the opposite phase. It gives a formal linkage value greater than 50 per cent. This value is always $1-y$, where $y$ is observed in the absence of reversal. An example is given below. A third reason is the difficulty of repeating striking results.

It is obviously desirable to have material from which repetitions can be made by workers who may wish to confirm my results. The best material, namely, segregating inbred lines and linkage groups, is fortunately available or is being constructed in this department as part of Sir Ronald Fisher's plan for the systematic detection of linkage and for accurate mapping. At his suggestion I have made up crosses between inbred lines and backcrossed to multiple recessives, in order both to discover new quasi-linkages, and to recognize them in material from which they can at any time be reproduced. As a result of this work, which is still in progress, a quasi-linkage has been obtained sufficiently striking to seem worthy of publication. Using the convention of real linkage, this may be represented as follows:

*Sd* ex line 4 × *Ca* (Caracul) ex line 10

One $\frac{Sd\ +}{+\ Ca}$ male × several $\frac{++}{++}$ females

| | ++ | *Ca* | *Sd* | *CaSd* | Total | Recomb. value | Linkage $\chi^2$ |
|---|---|---|---|---|---|---|---|
| *fz* | 18 | 10 | 6 | 13 | 47 | 65·96% | 4·7872 |
| + | 23 | 10 | 8 | 13 | 54 | 66·67% | 6·0000 |
| Total | 41 | 20 | 14 | 26 | 101 | 66·34% | 10·7872 |

The datum is divided into *fz* (fuzzy) and 'not *fz*', because this factor is also segregating as a backcross and, although fuzzy itself is quite unmistakable, *Ca* presents some difficulty of classification in the presence of *fz*. However, the two sets of data manifestly agree well.

A new cross between lines 4 and 10 has been set up in the hope that these lines are sufficiently inbred to allow repetition of these results.

It is encouraging, although not unexpected, that similar, if less striking, data have already been reported. Dunn, Gluecksohn-Schoenheimer and Bryson[2] give the following table:

| Cross | ++ | *Ca* | *Sd* | *CaSd* |
|---|---|---|---|---|
| +/*Sd* +/*Ca* × ++ | 50 | 33 | 35 | 43 |

The authors do not say from which parent the dominants of the double heterozygote came, but it seems probable that they were in repulsion, since *Sd* (which is here described for the first time) is not stated as occurring in a Caracul stock. The recombination value calculable on these data is 57·76 per cent, and the linkage $\chi^2$ is formally just significant at 3·8820. Dunn and his associates draw no conclusion from the data other than that "It (*Sd*) is probably not linked with Caracul (*Ca*)".

That the association between *Sd* and *Ca* apparent in these two bodies of data is not easily interpreted as real linkage, even on the basis of unusually strong interference, is indicated by the fact that another, comparatively large, body of repulsion data from this department shows almost perfect independence of *Sd* and *Ca*:

| Cross | ++ | *Ca* | *Sd* | *CaSd* | Total | Recomb. value | Linkage $\chi^2$ |
|---|---|---|---|---|---|---|---|
| $\frac{Sd\ +}{+\ Ca}$ × ++ | 60 | 65 | 56 | 62 | 243 | 50·21% | 0·0029 |

These results are in good accord with the theory of affinity.

A fuller account of observation and theory will be submitted later to *Heredity*.

# ENZYMATIC BREAKDOWN AND SYNTHESIS OF ACETOACETATE

By DR. JOSEPH R. STERN, DR. MINOR J. COON* and MISS ALICE DEL CAMPILLO

Department of Pharmacology, New York University College of Medicine, New York

ACETOACETATE and other β-keto-acids can contribute acetyl groups for citrate synthesis or sulphanilamide acetylation. Thus, cleavage of the β-keto-acid must yield acetyl coenzyme A. In pigeon liver[1] and yeast extracts[2] the reaction requires the presence of adenosine triphosphate and coenzyme A (CoA).

The formation of acetyl coenzyme A has now been directly demonstrated in extracts of pig kidney incubated with acetoacetate, adenosine triphosphate, and coenzyme A, in the presence of magnesium ions ($Mg^{++}$) and reduced glutathione. In all these cases, acetyl coenzyme A may be formed via the following reactions:

Acetoacetate + CoA + ATP ⇌ acetoacetyl CoA + adenosine-5-phosphate + pyrophosphate (1)

Acetoacetyl CoA + CoA ⇌ 2 acetyl CoA (2)

Reaction 1 would be analogous to the adenosine triphosphate–coenzyme A–acetate reaction, the mechanism of which has recently been elucidated by Lipmann and his collaborators[3].

As pigeon liver extracts can also catalyse the synthesis of acetoacetate[4] by a reaction involving two molecules of acetyl coenzyme A[5], it is possible that such synthesis in liver occurs by a reversal of reaction 2 (cf. Lynen *et al.*[6]) coupled with the action of a specific acetoacetyl coenzyme A deacylase (reaction 3):

* Research Fellow, United States Public Health Service

$$\text{Acetoacetyl CoA} + H_2O \rightarrow \text{acetoacetate} + \text{CoA} \qquad (3)$$

The acetoacetate synthesizing system has been purified seven-fold from ox liver extract using an assay (cf. Table 3) with acetyl phosphate, coenzyme A, and phosphotransacetylase as a source of acetyl coenzyme A[6]. The partially purified system synthesizes acetoacetate from acetyl coenzyme A (Table 1). It does not, however, cleave acetoacetate, in the presence of adenosine triphosphate and coenzyme A, to acetyl coenzyme A, and hence does not catalyse reaction (1)

TABLE 1. ACETOACETATE SYNTHESIS FROM ACETYL COENZYME A

The complete system contained tris(hydroxymethyl)aminomethane–hydrochloric acid buffer, pH 8·1, 30 micromoles; magnesium chloride, 8 micromoles; acetyl coenzyme A, 2·9 micromoles; ox liver ethanol fraction (27 mgm. protein). Volume, 3 0 ml.; temperature, 25°. The yield of acetoacetate is only 40 per cent of that expected from the liberation of sulphydryl (that is, coenzyme A), presumably as a result of acetyl coenzyme A deacylase activity. Acetyl coenzyme A was prepared chemically by the method of Wilson (ref. 7)

| Time (min.) | Sulphydryl liberation (micromoles) | Acetoacetate synthesis (micromoles) |
|---|---|---|
| 0 | 0 | 0 |
| 40 | 3·20 | 0·64 |

Another mechanism of formation of acetoacetyl coenzyme A has been suggested by experiments with enzyme preparations obtained from pig heart extracts by fractionation with ammonium sulphate and ethanol. These experiments, in which the formation of acetyl coenzyme A was followed through its reaction with oxalacetate to form citrate in the presence of an excess of condensing enzyme[8], support the occurrence in heart of the following sequence of reactions. (Similar reactions have been postulated independently by D. E. Green and co-workers[9].)

$$\text{Succinate} + \text{CoA} + \text{ATP} \rightleftharpoons \text{succinyl CoA} + \text{ADP} + \text{P} \qquad (4a)$$

$$\text{or}\quad \alpha\text{-Ketoglutarate} + \text{CoA} + \text{DPN}^+ \rightarrow \text{succinyl CoA} + CO_2 + \text{DPNH} + \text{H}^+ \qquad (4b)$$

$$\text{Succinyl CoA} + \text{acetoacetate} \rightleftharpoons \text{succinate} + \text{acetoacetyl CoA} \qquad (5)$$

$$\text{Acetoacetyl CoA} + \text{CoA} \rightleftharpoons 2\ \text{acetyl CoA} \qquad (6)$$

$$2\ \text{Acetyl CoA} + 2\ \text{oxalacetate} \rightleftharpoons 2\ \text{citrate} + 2\ \text{CoA} \qquad (7)$$

The basic observation is that heart extracts, or the enzyme fractions therefrom, synthesize little or no citrate from acetoacetate, coenzyme A, adenosine triphosphate, and oxalacetate, unless succinate is also present. Table 2 *A* shows that, in addition to succinate, citrate synthesis from acetoacetate and oxalacetate requires coenzyme A, adenosine triphosphate, and magnesium ions. The condensing enzyme was not limiting in the enzyme fractions employed. As previously observed by others[10], it has been found that two molecules of citrate are formed for each molecule of acetoacetate disappearing. Acetoacetate can be replaced by β-ketovalerate, β-ketohexanoate and β-ketoisohexanoate, in order of decreasing activity, but not by β-ketooctanoate or β-ketoadipate (Table 2 *B*). β-Hydroxybutyrate, butyrate, hexanoate and octanoate (tested with coenzyme I and II as hydrogen acceptors) and acetate are not active in this system.

TABLE 2. CITRATE SYNTHESIS FROM ACETOACETATE AND OTHER β-KETO ACIDS

(*A*) The complete system contained tris(hydroxymethyl)aminomethane–hydrochloric acid buffer, pH 7·5, 100 micromoles; potassium adenosine triphosphate, 10 micromoles; coenzyme A (85 per cent pure, obtained from the Pabst Laboratories, Milwaukee, Wisconsin, through the courtesy of Dr. A. Frieden), 0·1 mgm. (about 0·1 micromole of pure coenzyme A); magnesium chloride, 8 micromoles, reduced glutathione, 10 micromoles; potassium acetoacetate, 100 micromoles; potassium succinate, 100 micromoles; potassium oxalacetate, 20 micromoles; crystalline condensing enzyme, 5 units; 1ig heart enzyme fraction (6 mgm. protein) obtained by fractionation with ammonium sulphate and ethanol. Volume, 1·66 ml., incubation, 60 min. at 38°

(*B*) The complete system was the same as in (*A*) except that 100 micromoles of each β-keto-acid was added as indicated. The heart-enzyme fraction was similar to that used in (*A*) and contained 14 6 mgm. of protein

| *A* | | *B* | |
|---|---|---|---|
| Components | Citrate synthesis (micromoles) | Acetyl donor | Citrate synthesis (micromoles) |
| Complete system | 3·18 | None | 0 |
| No acetoacetate | 0 | Acetoacetate | 5·41 |
| No succinate | 0·03 | β-Ketovalerate | 1·66 |
| No adenosine triphosphate | 0·05 | β-Ketohexanoate | 0·93 |
| No coenzyme A | 0 05 | β-Ketoisohexanoate | 0·26 |
| No magnesium ions | 0·04 | β-Ketooctanoate | 0·02 |
| No oxalacetate | 0 | β-Ketoadipate | 0 |
| No condensing enzyme | 3·22 | | |

In the absence of oxalacetate, addition of stoichiometric amounts of acetoacetate, coenzyme A and adenosine triphosphate, together with magnesium ions and a reducing agent (glutathione or hydrogen sulphide), to the heart enzyme fractions results in the accumulation of acetyl coenzyme A provided succinate is also present. The acetyl coenzyme A was identified after deproteinization by its reaction with oxalacetate, in the presence of crystalline condensing enzyme, to form citrate and by paper chromatography[11]. Also, when β-ketovalerate (or β-ketohexanoate) is incubated with the heart fractions in the presence of the complete system minus oxalacetate, and neutral hydroxylamine is added later to trap thiol esters, the formation of acetohydroxamic and propionohydroxamic acids (or acetohydroxamic and butyrohydroxamic acids) can be demonstrated by chromatographic methods[12].

Reaction *4a* is catalysed by the system discovered by Kaufman[13] which is present in the heart fractions employed in this work. In heart acetone powder extracts, which do not contain α-ketoglutaric dehydrogenase, the succinate – coenzyme A – adenosine triphosphate system can be replaced by α-ketoglutarate, coenzyme A, and coenzyme I, in activating acetoacetate breakdown to acetyl coenzyme A, provided a purified α-ketoglutaric dehydrogenase fraction is added. α-Ketoglutaric dehydrogenase catalyses reaction *4b*[14].

Unlike liver, heart extracts do not synthesize acetoacetate in the presence of the acetoacetate assay system. However, they synthesize appreciable amounts of acetoacetate when succinate is added (Table 3). This synthesis apparently proceeds by reversal of reactions (6) and (5) coupled with the action of a succinyl coenzyme A deacylase (reaction 8[15]) present in the extract, thereby regenerating coenzyme A and allowing it to function catalytically.

$$\text{Succinyl CoA} + H_2O \rightarrow \text{succinate} + \text{CoA} \qquad (8)$$

In some heart fractions, the yield of acetoacetate in the presence of succinate is further increased by the addition of a purified succinyl coenzyme A deacylase from heart. Indeed, succinyl coenzyme A deacylase activity is so limiting in heart fraction III (Table 3) that both succinate and deacylase fraction are required for acetoacetate synthesis.

The free energy change of reaction (6) can be estimated from the energy content of the acyl

TABLE 3. ACETOACETATE SYNTHESIS WITH HEART ENZYMES
The acetoacetate assay system contained tris(hydroxymethyl)ammomethane–hydrochloric acid buffer, pH 8·1, 150 micromoles; magnesium chloride, 4 micromoles; potassium chloride, 50 micromoles; coenzyme A, 0 1 mgm., obtained from the Pabst Laboratories, Milwaukee, Wisconsin, through the courtesy of Dr A. Frieden (about 0·1 micromole of pure coenzyme A); lithium acetyl phosphate, 50 micromoles, L-cysteine, 20 micromoles; and 10 units of a partially purified phosphotransacetylase preparation from *Strep. haemolyticus*. Potassium succinate (100 micromoles) and a purified succinyl coenzyme A deacylase preparation (1·1 mgm. protein) from pig heart were added as indicated. The heart extract (5·6 mgm. protein) was made from pig heart acetone powder. Fraction 1 (11·8 mgm. protein) was an ammonium sulphate fraction (0 4–0 6 saturation) of the heart extract Fraction 2 (9·2 mgm. protein) was obtained from fraction 1 by precipitation with ethanol (20–40 per cent) at – 15°. Fraction 3 (6·1 mgm. protein) was equivalent to fraction 2 but made from an extract of fresh heart. Volume, 2·0 ml.; incubation, 60 min. at 38° (25° for fraction 3)

| Additions to assay system | Micromoles of acetoacetate formed | | | |
|---|---|---|---|---|
| | Heart extract | Fraction 1 | Fraction 2 | Fraction 3 |
| None | 0 (0)* | 0 06 | 0·22 | 0 |
| Succinate | 0·39 | 0·77 | 0·90 | 0 |
| Deacylase | 0·05 | 0·14 | 0·12 | |
| Succinate + deacylase | 0 47 (0·27) | 1·51 | 1·60 | 0·54 |

* Values in parentheses are for pig kidney extract

mercaptide bond of acetyl coenzyme A[8] (approximately 12,000 calories) and the calculated free energy of hydrolysis of acetoacetate[14] (16,000 calories). For the synthesis of acetoacetyl coenzyme A, $\Delta F \simeq 28{,}000 - 24{,}000 = +\ 4{,}000$ calories. This corresponds to an equilibrium constant of about $10^{-3}$. In heart, the equilibrium of reaction (6) can be shifted in favour of synthesis through coupling with reactions (5) and (8) when succinate is present. In liver, which does not catalyse reaction (5), this shift of equilibrium may be accomplished by the action of a specific acetoacetyl coenzyme A deacylase.

The occurrence of a reversible coenzyme A transfer from succinyl coenzyme A to acetoacetate (reaction 5) has important implications. If, as seems likely, acetoacetyl coenzyme A is generated by fatty acid oxidation, this process would result in phosphorylation at the substrate-level by reversal of reactions (5) and (4*a*).

We wish to thank Prof. Severo Ochoa for his interest in this work. We are indebted to Dr. S. Kaufman and Dr. C. Gilvarg for purified preparations of α-ketoglutaric dehydrogenase and succinyl coenzyme A deacylase from pig heart. The work was supported by grants from the United States Public Health Service, the American Cancer Society (recommended by the National Research Council Committee on Growth), the Williams–Waterman Fund of the Research Corporation, and by a contract between the Office of Naval Research and New York University College of Medicine.

# ELECTRON MICROSCOPY OF MITOCHONDRIA AND CYTOPLASMIC DOUBLE MEMBRANES

By DR. FRITIOF S. SJÖSTRAND
Department of Anatomy, Karolinska Institutet, Stockholm

## Ultra-Structure of Rod-shaped Mitochondria

BY means of an improved technique using a modified Spencer No. 820 rotary microtome[1] and specially polished razor blades[2], it has been possible to obtain tissue sections sufficiently thin to study the structure of tissue cells in sections at a resolution of better than 30 A.

A second factor of importance in this connexion is the improvement of the osmium fixation technique through the modifications recommended for electron microscopy by Pallade[3].

A third factor is represented by the demonstration by Hillier[4] of the deteriorating effect of removing the embedding medium by solvents exhibiting considerable surface forces when evaporating. To study the structure of the cells at a high resolution it is therefore necessary to avoid the removal of the embedding medium, although this means subjecting the sections to a high beam intensity.

The mitochondria have been studied at a resolution of about 30 A. in the retinal rods of the guinea pig eye, in the excretory cells of the mouse pancreas and (in collaboration with J. Rhodin) in the proximal convoluted tubules of the mouse kidney[5].

A similar structure has been revealed in all these cases, and the presumed identification of certain structural components as mitochondria in the retinal rods was based on the characteristic ultra-structure and was later confirmed by supravital staining with janus green *B*[6].

In all three kinds of cells the mitochondria are rod-shaped and lined by an outer double membrane. In the interior of the mitochondria there is a great number of transversally oriented inner double membranes with different spacings in the different types of cells studied. The outlines of these double membranes also differ in cells of different tissues, being rather irregular in the rod inner segment mitochondria. Fig. 1 illustrates the tubular cell mitochondria of the mouse kidney and Fig. 2 the rather similar appearance of the retinal rod mitochondria in the rod inner segment from the guinea pig.

The dimensions of the outer and the inner membranes are identical as measured in the electron micrographs. For the mitochondria of the proximal convoluted tubule cells, the mean total thickness is 160 A. This figure is the mean value of 1,200 measurements on twenty-five different mitochondria. The thickness of the two constituent single membranes is 45 A., and the space in between the single membranes measures 70 A.

The mitochondria of the retinal rods are located in the inner segment, where the long slender mitochondria are tightly packed, and the whole aggregation of mitochondria forms the so-called ellipsoid.

The double character of the membranes observed in the mitochondria does not depend upon a diffraction phenomenon, as the pictures represent close-to-focus pictures in through-focus series, and the two constituent single membranes exhibit

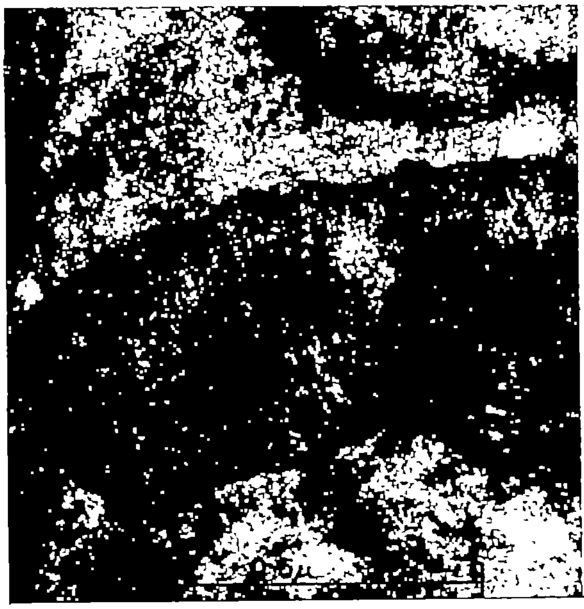

Fig. 1

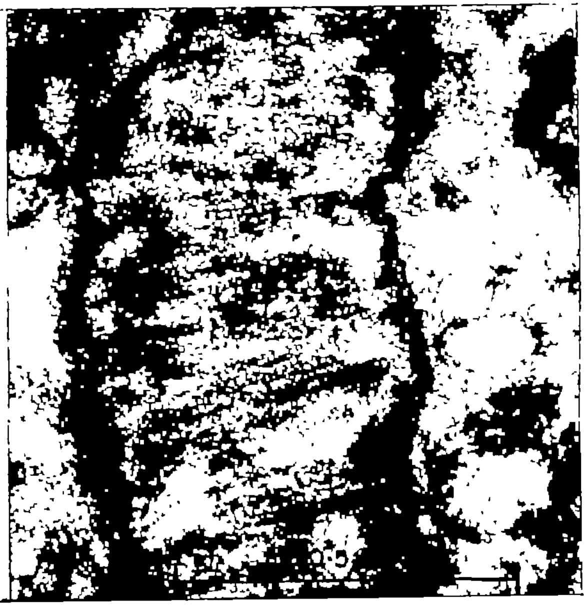

Fig. 2

Fig. 1. Part of a rod-shaped mitochondrion from the proximal convoluted tubule of mouse kidney; in the upper right corner a part of a cell nucleus with the double nuclear membrane and in the upper left corner a part of a cell granule. Along the lower side of the mitochondrion some intracellular cytoplasmic membranes are seen. Ultra-thin section. Magnification, × 97,000

Fig. 2. Part of a mitochondrion from the inner segment of retinal rod of a guinea pig eye. The transversally oriented double membranes are more irregularly arranged than in the tubular cells, due to the more irregular outlines when observed in a direction parallel to the long axis of the mitochondrion. Ultra-thin section. Magnification, × 90,000

sufficient deviations from a parallel course to demonstrate a certain mutual independence. On the other hand, the variations regarding the spacing are sufficiently small to justify considering the two membranes as parts of the same structural element.

Another possibility would be that the double appearance was due to a single membrane oriented obliquely to the direction of the electron beam and with an enhanced contrast along the cut margins of the membrane in the upper and the lower surfaces of the section. This is excluded by, among other conditions, the fact that the spacing is independent of the thickness of the sections.

Experience with osmium fixation shows that it is an excellent electron stain for protein membranes[7].

It has tentatively been assumed that the double membranes represent two membranes of mainly protein character separated by a double layer of lipid molecules. This assumption is supported by the dimensions measured, 45 A. representing a reasonable thickness for a protein membrane and 70 A. corresponding to the thickness of a double layer of, for example, mixed myelin sheath lipids[8]. ## Systems of Double Membranes in the Cytoplasm of Certain Tissue Cells

Recent developments of the technique for making ultra-thin sections for electron microscopy[1] have made it possible to study the ultra-structure of tissue cells at high resolution (better than 30 A.) with the topography of the structural elements preserved.

A rather highly developed system of double membranes was first observed in the cytoplasm of the excretory cells of the mouse pancreas preserved by freeze-drying and embedded directly after drying in *n*-butyl-methacrylate (Fig. 3). Suspecting that the striking organization might be an artefact due to a stepwise advance of freezing through the cell, osmium-fixed material was analysed. The same systems of double membranes were observed in this material (Fig. 4). These circumstances constitute good evidence that the double membranes are real structures and do not represent fixation artefacts, the osmium fixation and the freeze-drying acting according to quite different principles.

The double membranes are oriented mainly parallel to the cell membrane, and up to about forty double membranes may be observed in the space between the cell membrane and the nucleus.

Such a structure might produce an anisotropy of the cytoplasm. A preliminary polarization optical analysis of the living pancreas cells in the living mouse has revealed an anisotropy of the cytoplasm, negative with respect to a direction perpendicular to the cell surface and with the optical axis parallel to this direction. This anisotropy might well correspond to a system of membranes oriented parallel to the cell surface. The polarization optical analysis is still incomplete.

The electron microscopic observations on freeze-dried and osmium-fixed material thus seem to be confirmed by the polarization optical analysis on living cells.

The mean total thickness of the double membranes is 530 A. when measured on frozen-dried material and 600 A. when measured on osmium-fixed material. The mean distance between the centres of the two constituent single membranes is 370 A. and 360 A.

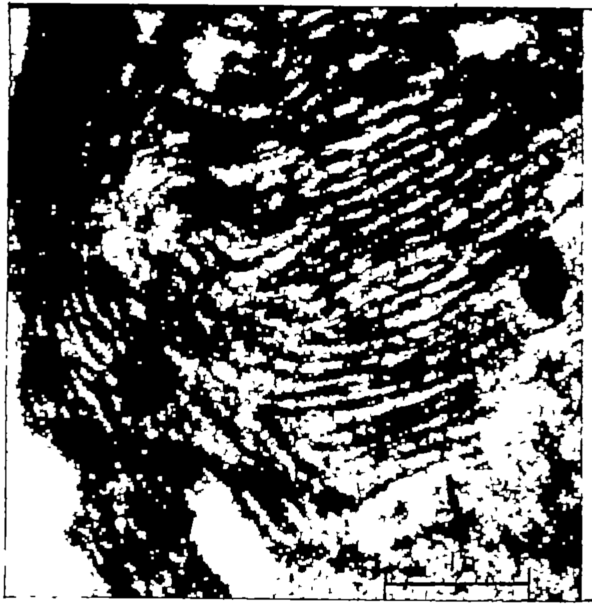

Fig. 3

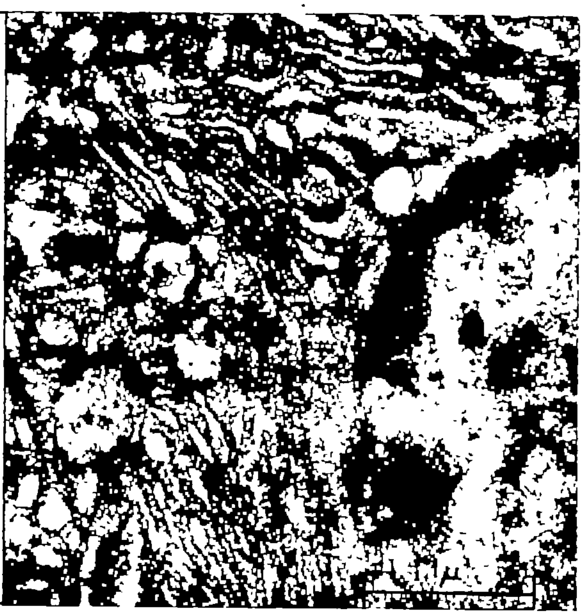

Fig. 4

Fig. 3. Cytoplasm of mouse pancreas excretory cell; fixation by freeze-drying. A characteristic pattern of double membranes. Thin section. Magnification, × 18,000

Fig. 4. Cytoplasm and part of the nucleus of a mouse pancreas excretory cell; buffered osmium fixation. A system of double membranes similar to those in Fig. 3 is shown. In the upper part of the picture several double membranes with wide spaces separating the two constituent single membranes are seen. Thin section. Magnification, × 22,000

for frozen-dried and osmium-fixed material, respectively. The calculated mean thickness of the single membranes is 160 A. (frozen-dried) and 240 A. (osmium-fixed), and the width of the space between the two membranes of the double membrane is 210 A. (frozen-dried) and 120 A. (osmium-fixed). These figures are preliminary, as each is based on only sixty to eighty measurements.

The double membranes appear coarser after osmium fixation than after freeze-drying, presumably due to osmium-stained components with a close topographical relation to the membranes or to the precipitation of proteins at the membranes.

Intracellular double membranes have also been observed in the cells of the proximal convoluted tubules of mouse kidney[2], and in the epithelium of mouse intestines. In the kidney tubular cells the intracellular membranes occur in the basal cell zone and divide the cytoplasm into compartments containing the mitochondria. The total mean thickness of these double membranes is 270 A. (mean value of 600 measurements on twenty-five membranes), the thickness of the constituent single membranes 80 A., and the width of the space between the single membranes 110 A.

These figures show a distinct difference in dimensions between the intracellular cytoplasmic membranes of the pancreas and of the kidney cells. They also differ in regard to the effect caused by the osmium fixation. The double membranes of osmium-fixed pancreas cells often appear deformed, with the two constituent single membranes separated by more-or-less wide spaces. The double membranes may even appear as wide tubules. As the double membranes do not show this appearance in frozen-dried material, it seems reasonable to assume that the wide spaces are due to the osmium fixation causing a swelling of the double membranes.

The double membranes of the tubular cells of the kidney and of the epithelial cells of the intestines have not been observed to exhibit that deformed pattern. On the contrary, the distance between the constituent single membranes of these double membranes is fairly constant.

The double membranes of the pancreas cells thus differ considerably from the double membranes in the kidney and intestinal cells both in dimensions and variability of the spacing. It therefore seems justified to assume that we are dealing with rather different intracellular double-membrane structures.

The intracellular cytoplasmic membranes seem to correspond to the coarse cytoplasmic fibrils first observed by J. Hillier[3] in liver cells in connexion with his work on improving the sectioning technique and recently described by Bernhard, Gautier and Oberling[4] in liver, pancreas and salivary gland cells.

Double-membrane structures have also been observed as an important structural element of the mitochondria[5] and in the outer segments of the retinal rods of guinea pig and perch eyes[1].

The following interpretation of the observations is proposed. The two constituent single membranes represent membranes of mainly protein nature and the space between represents a multilayer of lipid molecules, partially dissolved during the embedding. This tentative interpretation seems justified, at least for the intracellular double membranes of kidney and intestinal cells. The structural organization of the double membranes of the pancreas cells, on the other hand, may well be more complex.

The intracellular cytoplasmic membranes may represent a fundamental principle of organization of the cytoplasm. [Aug. 22.

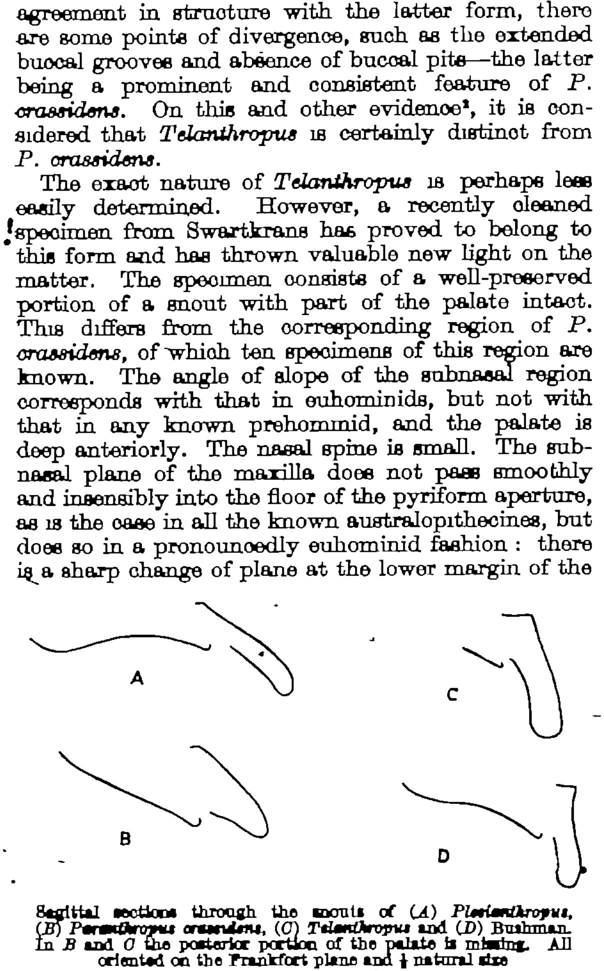
## The Nature of *Telanthropus capensis*

THE type mandible of *Telanthropus capensis* was found in the Swartkrans excavation in April 1949 by me. Dr. R. Broom and I published a preliminary description in this journal[1]. In this note the opinion was expressed that this form is "intermediate between one of the ape-men and true man". This conclusion has been somewhat sceptically received by most workers, who consider, in view of the fact that the same excavation has yielded numerous remains of the ape-man *Paranthropus crassidens*, that the specimen is more likely to be a small and slightly aberrant *P. crassidens* than a new type of man.

Hitherto the known specimens of this form comprised only the almost complete mandible containing five molars, $P_3$ belonging to the left side of the same mandible and the proximal end of a radius. The teeth are small compared to the *P. crassidens* homologues—especially $M_1$. The length and breadth values for $M_1$, respectively, fall 5·4 and 3·8 standard deviations from the corresponding means for $M_1$ of *P. crassidens*. The ascending ramus and corpus mandibulæ heights are appreciably lower than those of *P. crassidens*. Although the molars show general agreement in structure with the latter form, there are some points of divergence, such as the extended buccal grooves and absence of buccal pits—the latter being a prominent and consistent feature of *P. crassidens*. On this and other evidence[2], it is considered that *Telanthropus* is certainly distinct from *P. crassidens*.

The exact nature of *Telanthropus* is perhaps less easily determined. However, a recently cleaned specimen from Swartkrans has proved to belong to this form and has thrown valuable new light on the matter. The specimen consists of a well-preserved portion of a snout with part of the palate intact. This differs from the corresponding region of *P. crassidens*, of which ten specimens of this region are known. The angle of slope of the subnasal region corresponds with that in euhominids, but not with that in any known prehominid, and the palate is deep anteriorly. The nasal spine is small. The subnasal plane of the maxilla does not pass smoothly and insensibly into the floor of the pyriform aperture, as is the case in all the known australopithecines, but does so in a pronouncedly euhominid fashion: there is a sharp change of plane at the lower margin of the pyriform aperture. The bony plate inside the nasal aperture is almost at right-angles to the subnasal plane. The left canine socket is intact except for the outer wall and is too small to accommodate even the smallest lower canine root of *P. crassidens*. The smallest upper canine root of the latter form is much too large for this socket. This probably means that in *Telanthropus* both the crown and root of the canines were reduced in size, whereas in *P. crassidens* the crown had been reduced but not the root. From the various fragments of $P^3$ preserved on both sides, it seems that this tooth was still three-rooted; which condition is also found in the australopithecines.



Sagittal sections through the snouts of (*A*) *Plesianthropus*, (*B*) *Paranthropus crassidens*, (*C*) *Telanthropus* and (*D*) Bushman. In *B* and *C* the posterior portion of the palate is missing. All oriented on the Frankfort plane and ½ natural size

This snout differs, therefore, in a number of important features from those of the australopithecines and approaches the condition in the earliest known euhominids very closely. In conjunction with the characters of the mandible, there seems little doubt that *Telanthropus* is a very primitive euhominid. There are some australopithecine affinities, and it is therefore difficult to avoid the conclusion that this form had recently passed from australopithecine to euhominid status.

Recent geological and faunal evidence[3] strongly suggests that the Swartkrans site is Upper Pliocene in age and that it is all a uniform deposit, that is, that the *Telanthropus* and *P. crassidens* remains are coeval. *Telanthropus* is therefore of very great interest and significance for studies on hominid phylogenesis. It demonstrates the very close relationship between australopithecines and man, and is almost certainly the oldest euhominid so far known. A fuller account is being published elsewhere.

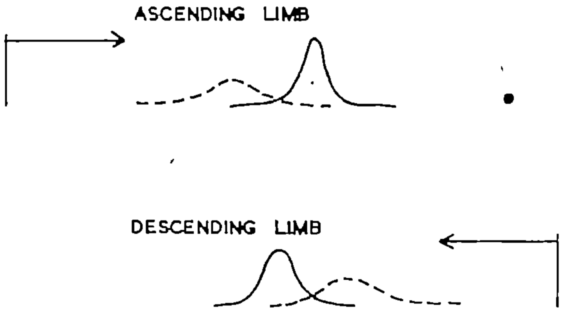
## Separation of an Inhibitor of Influenza Virus Hæmagglutination from Human Sputum

A SIMILARITY exists between the action of the influenza virus enzyme on the surface of the erythrocyte or cells of the respiratory tract and its action in destroying the inhibitory properties for virus hæmagglutination possessed by certain soluble mucins. This has stimulated much interest in the biological function of the mucins in relation to influenza virus infection and particularly in their chemistry as substrates for influenza virus enzyme action[1]. Although studies since 1948 have dealt with influenza virus action on a variety of inhibitors, ranging from those obtainable from serum and urine to those from egg-white, sheep salivary gland and human ovarian cyst, relatively little attention has been paid to the inhibitors present in the secretions actually at the site of influenza virus infection, namely, those in the human nasal and bronchial mucus. Fazekas[2] has described the change in 'inhibitor profile' for certain influenza viruses which takes place in human nasal mucus during influenza. Rose[3] has reported that sputum contains factors which inhibit both infectivity (in eggs and mice) and hæmagglutination by influenza virus.



Electrophoresis of sputum inhibitor in potassium phosphate buffer (pH 7·0, $\mu$ = 0·1) at 3·2 volt/cm. for 14,400 sec. Concentration approximately 0·4 per cent. Before (———) and after (– – – – –) treatment with receptor-destroying enzyme

Preliminary experiments carried out by us to extend the observations of Rose have shown that the factor present in some sputa which inhibits the growth of influenza virus *in ovo* seems to be distinct from the factor constantly present in all sputa which inhibits hæmagglutination *in vitro* by both enzymically active and 'indicator' viruses. It has been possible to extract from sputum an inhibitor of hæmagglutination which appears to be a single substance. The purification and properties of this inhibitor are described in this communication.

Samples of sputum, from patients with chronic bronchitis, were homogenized for five minutes in a Waring blendor in ten times their volume of physiological saline. The solution was centrifuged (5,000 *g*, 20 min.) to remove bacteria and cell debris. The supernatant was centrifuged (20,000 *g*, 25 min.) to remove an aggregated mucinous component. The inhibitor was precipitated from this supernatant by the addition of an equal volume of acetate buffer ($p$H 3·6, ionic strength ($\mu$) = 1·0, containing 0·02 *N* calcium chloride). The presence of calcium ions was found necessary for satisfactory precipitation. The precipitate was recovered by centrifugation (3,000 *g*, 10 min.) and dissolved in a minimum volume of phosphate buffer ($p$H 7·0, $\mu$ = 1·0). The resulting slight precipitate of calcium phosphate was removed by centrifugation (2,000 *g*, 15 min.). The supernatant was submitted to electrophoresis in phosphate buffer ($p$H 7·0, $\mu$ = 0·1). A single component migrating towards the anode with a mobility of $6 \cdot 7 \times 10^{-5}$ cm.$^2$ sec.$^{-1}$ volt$^{-1}$ was found (see diagram). After treatment with a purified preparation[4] of the receptor-destroying enzyme of *Vibrio choleræ* the mobility of this component was reduced to $4 \cdot 9 \times 10^{-5}$ cm.$^2$ sec.$^{-1}$ volt$^{-1}$. This reduction in mobility after the action of the receptor-destroying enzyme has been found to be general for inhibitors and gives an indication of the uniformity of the substance as an inhibitor[5].

The inhibitory titres of the samples submitted to electrophoresis were estimated according to the method of Stone[6], using the viruses shown in the table.

## Aureomycin in *Theileria parva* Infection

Recognition of the selective action of quinine, atebrin and chloroquine on the hæmotropic trophozoites of certain *Plasmodium* species, and that of plasmoquine on the exoerythrocytic trophozoites as well as on the gametocytes, forms the bases of modern chemotherapy of malaria in laboratory animals and in man.

Application of this conception of selective chemotherapeutic action to other diseases caused by protozoa, the life-cycle of which is similar to that of the malarial parasite, notably the *Theileria* spp., appeared to be indicated. Neitz[1] reported that the 8-aminoquinoline preparation plasmoquine has a selective action on the hæmotropic forms of *Theileria parva*, while leaving the schizont phase unaffected. Therefore the drug had no curative value. The investigation was extended to include other drugs, among which was aureomycin. The antibiotic, administered intravenously in repeated large doses during the incubation period of infection, has been found to exert a marked effect upon the schizonts of *Theileria parva*. In fact, in each of seven cases of sporozoite-induced theileriasis, disappearance of schizonts was followed by recovery and the development of a solid immunity.

For these tests, nine cattle were used, of which two served as untreated controls. In each case the disease was induced by feeding infective *Rhipicephalus appendiculatus* nymphæ on the left ear. Treatment was commenced 24 hr. later by the injection of aureomycin in a dose of 10 mgm. per kgm. body-weight. The same dose was repeated at arbitrary irregular intervals as indicated in the accompanying table, until a decrease in the number of schizonts in lymph gland smears became evident. In each case from this stage the number of schizonts continued to decrease rapidly until they could no longer be found after prolonged search. Hæmotropic forms of the parasite persisted from one to five days after disappearance of the schizonts. Apart from an exceedingly mild febrile reaction and swelling of the superficial lymph glands, the animals showed no clinical evidence of the disease. After complete recovery, it was shown that a solid immunity to re-infection had been induced in one animal tested four weeks after disappearance of the schizonts. The immunity of the remaining six survivors will be tested after longer intervals.

In the untreated controls the normal fulminating form of the disease was produced, followed by death not later than the twenty-fourth day after attachment of the ticks.

X, treatment with aureomycin; S2+, schizonts 2+ present in smears; P+, hæmotropic parasites present; + very rare; 2+, rare; 3+, fairly frequent; 4+, frequent; 5+, numerous

Thus aureomycin in a dose of 10 mgm. kgm. body-weight administered in repeated doses during the incubation period of *Theileria parva* infection is a schizonticide which acts on the early schizonts by suppressing nuclear division. This in turn suppresses the formation of merozoites, which invade either the lymphocytes or erythrocytes. The drug appears to have no effect upon the hæmotropic parasites. The result is that completion of the cyclical development of sporozoite-induced infection is inhibited and the clinical disease fails to develop. Nevertheless, a solid immunity is produced.

There remains to be determined the minimum effective dosage and the effect possibly in combination with a drug affecting the hæmotropic parasites, for example, plasmoquine administered at a later stage of parasite development.

## A New Technique for Microscopic Preparations of Small Marine Animals

During a recent study of the platyctenid ctenophores of Jamaica, the following technique was devised to allow even the most delicate and minute platyctenid to be immobilized, fixed, stained and embedded in any desired position with the minimum distortion. As this method has since been used successfully with rhabdocœl turbellaria, it is felt that its usefulness might well be extended to a wider range of invertebrates.

The chief difficulty in obtaining flat, uncontracted specimens of these delicate animals is their marked intolerance of usual anæsthetics such as menthol, magnesium sulphate, urethane or chloral hydrate. Treatment with warm fixative is also very often unsuccessful, as the animals begin to contract as soon as the fumes of the fixative reach them before the liquid can be applied. The usual refrigerator 'freezing and thawing in fixative' method is also of no use as the animals either dissolve while in the ice cube, or become only partially fixed, or become fixed in an unnatural position. These difficulties have been overcome by the following method.

(*a*) *Immobilization and Fixation.* The platyctenid is allowed to take up either its normal 'sitting' position in a drop of sea water on a coverslip (preferably No. 1 thickness) or is allowed to flatten itself under the surface film of the drop. The coverslip is then gently transferred to the stage of a freezing microtome. The animal is given a moment or two to recover from any jarring, and then the supply of carbon dioxide from the cylinder is turned on. The sea water drop is carefully watched until it just becomes opaque, then the carbon dioxide is turned off. The drop continues to freeze for a few moments, and it is during this interval that the fixative is added drop by drop. After the fourth or fifth drop of fixative the sea water begins to thaw, but the animal remains motionless and the requisite amount of fixative may be poured on. Fixatives which can be recommended are, in order of preference, (1) Komai's[1] modification of Carnoy–Lebrun, consisting of 70 parts saturated aqueous sublimate solution, 30 parts 95 per cent alcohol, and 1·5 parts glacial acetic acid; and (2) Duboscq–Brasil.

(*b*) *Staining for Whole Mounts.* The animal remains attached to the coverslip after freezing with carbon dioxide, and staining may therefore be carried out by the gentle removal of the coverslip with the animal from one Petri dish to another. The final mount is obtained by inverting a slide over the animal in a drop of mountant on the original coverslip. The staining process should be as rapid as possible because of the fragile nature of the specimen. A progressive stain such as aceto-carmine usually gives good results and makes the addition of a differentiator to the list of staining solutions unnecessary.

(c) *Embedding*. The animals may be prepared for embedding in paraffin, ester wax[2] or in celloidin by a very simple modification of the above technique. A small square of thin 'Cellophane' is placed on the coverslip and held in position by a drop of sea water. A further drop is then placed on the upper surface of the 'Cellophane' and the animal transferred from the aquarium to this drop. Upon freezing as in section (a), the animal will now adhere to the 'Cellophane' instead of to the coverslip. After fixation and thawing, the coverslip with the 'Cellophane' and animal is transferred to 70 per cent alcohol and is then taken through the usual solutions for either wax or celloidin embedding.

For ease of handling of the coverslip, especially in celloidin solutions, a cradle made of fine copper wire and suspended from the cork by thread will be found to be helpful. In the actual embedding process, the coverslip, which merely acts as a stiffening support, is removed, but the 'Cellophane' is embedded along with the animal and may then be stripped off just prior to cutting.

Clearly this method of fixation owes much of its success to controlling the degree of freezing, which necessitates keeping the animal under observation from start to finish of the process. This can easily be tested in two simple experiments. First, if platyctenids are frozen into a hard block of ice and then allowed to thaw (without fixation), they will disintegrate, chiefly because the character of the mesoglœa appears to be altered, so that it is no longer capable of holding the animal together. This may perhaps be related to the high water content of the animal. Secondly, if the animals are frozen only slightly, as suggested in section (a) (without fixation), they will recover completely, and their normal movements may again be studied under the microscope.

The possibility that the carbon dioxide may have a gentle anæsthetizing effect cannot be entirely ruled out; but further experimentation would be required to elucidate this point.

## X-Ray Evidence for Metal-to-Metal Bonds in Cupric and Chromous Acetate

As a preliminary to the structural determination of chromous acetate, it was decided to study the much more stable cupric acetate $Cu(CH_3COO)_2.H_2O$ during the early X-ray investigations. Both these compounds are monoclinic with space group $C2/c$, and their unit-cell dimensions, determined from X-ray measurements and given herewith, are almost identical.

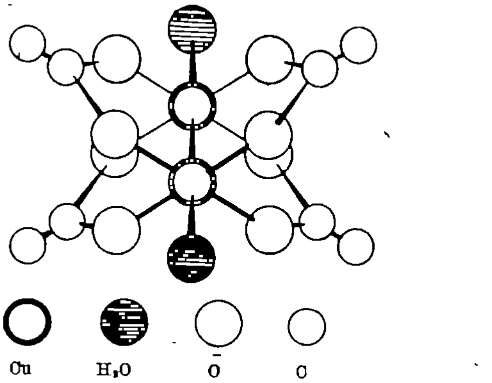
| | *a* | *b* | *c* | *β* |
|---|---|---|---|---|
| Cupric acetate | 13·15 | 8·52 | 13·90 A. | 117° 0′ |
| Chromous acetate | 13·15 | 8·55 | 13·94 A. | 117° 0′ |

The values for cupric acetate are in good agreement with those found by Hull and given in the "Handbook of Chemistry and Physics" (13th edit., p. 2060).

The close resemblance between these two acetates suggests that they are structurally isotypes, so that it appeared likely that an X-ray examination of cupric acetate might give information as regards the structure of the unstable chromous acetate.

Assuming eight $Cu(CH_3COO)_2.H_2O$ formula units in a cell with the above dimensions, the calculated density is 1·92 gm.cm.$^{-3}$, which is the same as the value determined experimentally by the method of flotation. Patterson projections, Harker sections and Fourier projections of the structure on three crystallographic planes show that the true repeat unit is $Cu_2(CH_3COO)_4.2H_2O$. It was further found that the symmetry centre of this dimeric molecule coincides with a symmetry centre of the $C2/c$ space group. The unit cell therefore contains only four molecules.

The accompanying diagram is of the cupric acetate molecule, obtained by calculating bond-lengths and angles from the projections. The nearest six neighbours of a copper atom are comprised of four oxygen atoms belonging to four different acetate groups, a copper atom and a water molecule. These six atoms form a distorted octahedral configuration about each of the two copper atoms in the molecule. The Cu–O distances all approach the value 1·97 A., which is in good agreement with the normal Cu–O [1] and Cr–O [2] distances found in other compounds. The four acetate groups are separately planar and their dimensions conform to previously determined bond-lengths and angles. The Cu–$H_2O$ distance is 2·20 A. The Cu–Cu distance is 2·64 A., and is only slightly longer than the value 2·56 A. found in metallic copper.



The ability of acetate groups to bridge two metal atoms in a complex has been predicted by Werner[3] from chemical reasoning. The cage-like structure of cupric acetate clearly illustrates this point. An unusual feature of this structure is the fact that, in addition to each copper atom forming four covalent bonds to four oxygen atoms, there also appears to be a fifth bond between the two copper atoms in a molecule. The nature of this metal-to-metal bond is at present being investigated by making an X-ray study of the acetates of the transition elements.

Experiments now in progress suggest very strongly that cupric acetate and chromous acetate are, in fact, structurally isotypes, and that similar bond-distances accordingly exist in the latter.

A detailed account of this work will shortly be published elsewhere. This communication is published by permission of the South African Council for Scientific and Industrial Research.

## Surface Free-Energy of Solid Paraffin Wax

As part of a programme of research on the surface free-energy of solids, we have lately been working on paraffin wax. The method used is the one proposed by Bergren[1] and consists in measuring the rates of elongation or contraction of thin filaments of different lengths hanging under their own weights. The change in length results from two opposing forces: one which tends to shorten the filament so that its surface free-energy is decreased, and the other tending to lengthen the filament because of its weight. A critical filament-length, $l_0$, is determined at which the elongation of the upper part of the filament is equal to the contraction of the lower part, so that the length remains constant. Assuming that the solid near the melting point behaves as a viscous liquid, that is, the rate of deformation is proportional to the applied stress, the surface free-energy of the solid can be calculated from the critical length $l_0$ using the equation:

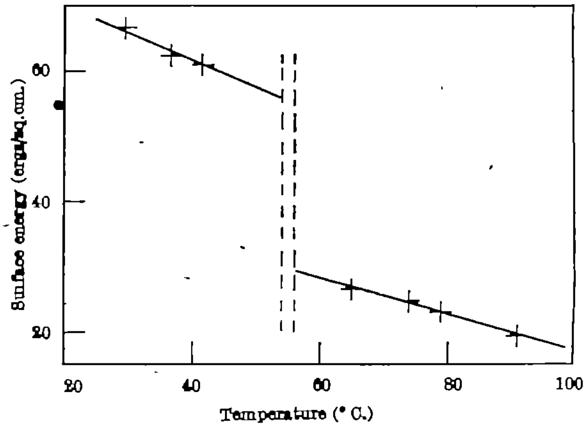
$$\gamma = \tfrac{1}{2}\rho g r l_0,$$

where $\gamma$ is surface free-energy, $\rho$ is density of solid at temperature of experiment, $g$ is acceleration due to gravity, and $r$ is radius of wire.

In our experiments, filaments of 0·01088 cm. radius were produced by extrusion of the paraffin wax (melting range 54–56° C.) through a tungsten carbide die at room temperature into a constant temperature ($\pm$ 0·1° C.) enclosure. The observations were then made on the filament hanging from the die. The change in length was measured at intervals by means of a cathetometer, and $\Delta l/l\Delta t$ (positive or negative) plotted against the original length of the filament. This should be a straight line according to theory, and $l_0$ was obtained by interpolation as intercept on the length axis.

Measurements were carried out at 29·5°, 36·7° and 41·5° C., and the surface free-energy calculated using $\rho_{20^\circ\text{C.}} = 0\cdot8857$ gm./cm.$^3$, the change in density being negligible over the temperature-range concerned. The results are plotted in the accompanying graph, together with values for the same specimen of paraffin wax in the liquid state determined by the ring tensiometer method and corrected by the method of Harkins and Jordan[2].

The results indicate a discontinuity in the surface free-energy on melting. On the other hand, the temperature coefficient of the surface free-energy does not alter appreciably.



Surface free-energy of solid and liquid paraffin wax

The same method has been used for measuring the surface free-energy of tin (99·99 per cent pure) *in vacuo* at 215° C. (17° below melting point). Polycrystalline wires with transverse grain boundaries (1/25 cm. average longitudinal grain-size) were extruded from the electrically heated die directly into the evacuated constant-temperature chamber. After correcting for the grain boundary energy according to Udin[3], the surface free-energy at 215° C. was found to be 685 ergs/cm.$^2$.

Further work on the surface free-energy of tin and other low-melting metals at different temperatures is in progress. A detailed account of this will be published later.

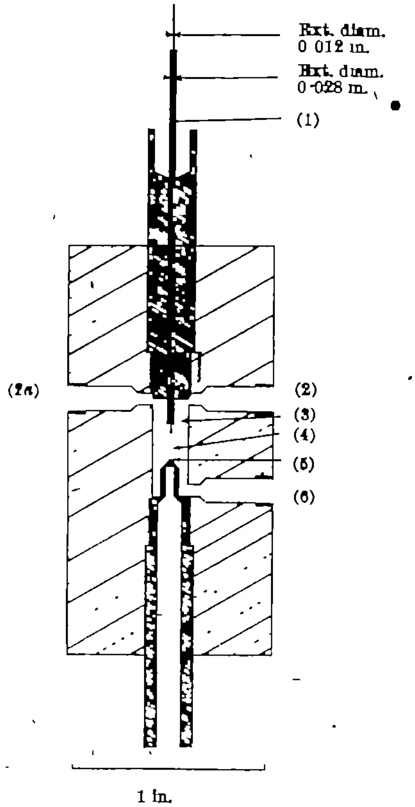
## A Device for Counting Small Particles suspended in a Fluid through a Tube

ATTEMPTS to count small particles suspended in fluid flowing through a tube have not hitherto been very successful. With particles such as red blood cells the experimenter must choose between a wide tube which allows particles to pass two or more abreast across a particular section, or a narrow tube which makes microscopical observation of the contents of the tube difficult due to the different refractive indices of the tube and the suspending fluid. In addition, narrow tubes tend to block easily.

These difficulties can be overcome by slowly injecting a suspension of the particles into a faster stream of fluid flowing in the same direction. Provided there is no turbulence, the wide column of particles will then be accelerated to form a narrow column surrounded by fluid of the same refractive index, which in turn is enclosed in a tube which will not interfere with observation of its axial contents.

This principle has been applied to the alignment of red blood cells preparatory to electronic counting. The constructional details of the apparatus in use are shown in the diagram.



(1) Needle in holder; (2) and (2a) inflow tubes; (3) wide-bore tube; (4) observation area for (3), (5) vortex; (6) flushing tube

The whole apparatus is filled with gas-free distilled water which is allowed to flow via tubes 2 and 2*a* into the wide tube 4 and into the vortex 5. Tube 6 is normally closed. The suspension of cells is then passed into the needle (1). As the stream of cells emerges from the tapered tip of the needle it is narrowed by the faster peripheral stream in 3, and as the vortex is approached the stream of cells narrows further as the velocity increases.

To be robust and serviceable, the chamber is made of a solid brass block, drilled and tapped so that all the five tubes can be removed for cleaning or replacement. Three side tubes are used. By using tubes 2 and 2*a* for water to enter the chamber, the stream of cells passing from the needle to the vortex loses its tendency to curve which occurs if water enters from one side only.

Tube 6 is connected to a source of negative pressure. It is normally closed; but it is useful for flushing air or foreign material from the chamber.

Tube 3, which is circular in cross-section, approaches a square cross-section at the observation area (4). Here the walls are cut away and replaced with flat glass cover-slips sealed to the brass with wax compound. Ideally, tube 3 should be tapered and, from the point of view of accelerating the cells, rather narrower than it is. The needle and vortex are aligned as accurately as possible to be central to the wide bore.

The needle should be wide enough not to block easily but, provided it does not block, should be as narrow as possible to enable the velocity of cells passing through the needle to be substantially greater than the sedimentation effect of gravity. A further reason for a narrow needle is that if a constant flow-rate is used as a measure of the volume of cell suspension to be counted, the fluctuations of flow in a wide-bore needle will be greater for the same minute changes of pressure. A bore of about 125 μ has been found suitable. The needle is made of stainless steel.

The vortex tube has a small hole of 0·16 mm. diameter at its tip, the walls of which are tapered to 45° to reduce their optical interference when observing cells entering the tube. This tip is made of platinum to avoid corrosion. A negative pressure of 25 cm. of mercury is applied to the vortex. Poiseuille's formula and its derivatives and corrections cannot usefully be applied to flow in the chamber because the flow approaching the vortex has a radial component and also on account of cells interrupting the smooth gradient of pressure from the periphery to the centre.

The chamber at present in use functions moderately well. Dark-ground illumination is used, and a thin luminous stream of cells less than 10 μ wide, wavering slightly (not more than 5 μ to either side), is seen approaching the vortex but cannot be seen as it enters. The speed has been estimated as being between 3 and 6 cm./sec. as judged by oscilloscope measurements of the cells crossing a field of about 5 μ. It is hoped that this speed will be increased by redesigning the chamber with decreased diameter of the observation area, which at present is 3/16 in.

I am indebted to Dr. J. Cox for the construction of the apparatus, and to Messrs. Accles and Pollock. Ltd., who supplied the steel tubes.

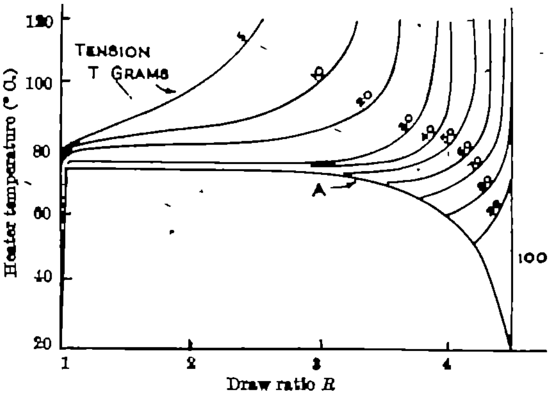
## Drawing Synthetic Fibres

THERE are two aspects of the drawing of synthetic fibres which have not so far been treated very fully in the literature. These are, respectively, the behaviour of the fibre during continuous drawing on the machine (as opposed to simple stretching on a tensometer) and the formation and maintenance of a 'neck' during drawing[1]. These two problems are intimately related to one another, since a continuous drawing machine, operating as a steady-state tensometer, is a particularly suitable tool for examining 'necking'.

The starting point was to consider continuous machine drawing in terms of a three-dimensional load–extension–temperature surface characteristic of the material, which during most of our investigation has been polyethylene terephthalate ('Terylene'). A 'contour map' for such a surface for this material is shown in the accompanying graph.

It has been found that during continuous drawing between two rolls, with a heater mounted between, the extensions occurring in the yarn at all points in the thread-line can be explained in terms of this surface, whenever the yarn tension is less than that required to form a 'neck' in the cold fibre. Most of this region lies above the second-order transition tem-



Denier, 280; heater, 4 in. hot plate; speed, 7·5 cm./sec.

perature of the polymer, and drawing is then always uniform at all machine ratios.

Outside this region, where the tensions mount very rapidly, the material 'necks' at a ratio independent of the machine setting, but dependent on the diameter and initial molecular orientation of the specimen and upon the absolute speed of the machine. This is the normally observed 'cold-drawing' of the fibre. Under these conditions, the neck advances or retreats along the thread-line at a steady velocity which can be measured and used to calculate the natural draw ratio in the neck. In the graph the natural draw ratio thus calculated, for fibres of polyethylene terephthalate, is shown by the line $A$.

The natural draw ratio drops to unity at about 80° C. in the range of the second-order transition of the polymer[2].

Consideration of the phenomenon in the terms of the surface suggests strongly to us that it is due to self-heating of the specimen to a point where the effective load-extension curve becomes horizontal; that is, to where the extension occurs at constant load but rising temperature, rather than constant temperature and rising load. Conditions for this to happen can readily be calculated for model substances having simple load-extension temperature properties, when the essential criteria for 'necking' to occur appear to be: (1) a modulus which falls with increasing temperature; (2) a sufficient rise in temperature of the material caused by the work of stretching. This in turn implies: (*a*) poor conductivity; (*b*) that the work done appears as heat rather than elastic potential energy; (*c*) that heat losses must be small. Crystallinity in the material does not appear to be essential.

Parallel observations on such substances as nylons, polyethylene, gutta percha and polymethylmethacrylate, which is amorphous, appear to support these conclusions.

We hope to publish this work elsewhere at greater length.

## Resolution of Racemic Mixtures by Symmetrical Agents

THE recent communication by H. M. Powell[1] on new procedures for resolution of racemic substances by means of perfectly symmetrical agents prompts me to describe my own researches on the same subject. A full account of our results, including experimental details, is to be published in the *Anais Soc. Biol. Pernambuco*[2]. Although the method outlined below is very simple, apparently it has not been mentioned in the literature[3].

The proposed method is based upon the following assumptions: it is well known that optically active adsorbents preferentially adsorb one of the enantiomorphs from a racemic mixture[4,5]. When a crystalline racemic substance is precipitated from its solution, a crystallization nucleus is first developed. Since this nucleus contains a relatively small number of molecules there is more than an even chance that it will contain an excess of one enantiomorph or the other. Supposing that the forces acting in the growth of a crystal are of the same kind as those responsible for adsorption, this nucleus will grow preferentially, collecting one of the optical antipodes at the expense of the other, which will remain in the solution. Usually in a macro-crystal of dissymmetrical molecules obtained under perfectly symmetrical conditions the antipodal forms are so nearly equivalent in number that it is impossible by experimental means to prove the existence of an excess of one of the enantiomorphs, but this numerical equality only represents a statistical mean. It is possible, however, to increase the statistical fluctuations so that resolution can be shown.

In our experiments a racemic alkaloid, prepared synthetically (such as DL-narcotine or DL-laudonosine), insoluble in water, is first dissolved in hydrochloric acid, and a symmetrical organic base (pyridine) is then slowly poured into the solution, causing the re-precipitation of the alkaloid:

$$\text{pyridine} + [B\text{H}]^{+}\text{Cl}^{-} \rightarrow [\text{pyridine.H}]^{+}\text{Cl}^{-} + B.$$

After a small precipitate has formed, it is filtered off and the solution tested for optical activity. In our experiments with DL-narcotine and DL-laudonosine, resolutions ranging from 1 up to 2·5 per cent were achieved. The method can be applied to many other substances, and experiments are in progress on the resolution of DL-cystine and DL-tyrosine.

Finally, we wish to stress the implications of these findings (as well as those of Powell) on the problem of the origin of molecular dissymmetry in living matter. Processes such as those recently described are probably more likely to have occurred in the past than the activation of reactive racemic mixtures by naturally polarized light, even if they lead to a spontaneous decrease in the entropy of the system.

## Emission of Molecular Complexes of Nitro-compounds

Lewis and Kasha[1] have directed attention to the phosphorescence induced by ultra-violet light on a number of organic compounds, particularly nitro-compounds, dissolved in the 'glass' produced when their solutions in suitable solvent mixtures are cooled to liquid-air temperature. They attribute this phenomenon to the formation of triplet-levels from the original excited singlets, the phosphorescence resulting from the triplet – ground-level change being unquenched owing to the greatly diminished thermal agitation at low temperatures in the glass.

We have found that even at ordinary temperatures an intense brick-red fluorescence is produced in ultra-violet light when an acetone solution of *s*-trinitrobenzene is shaken with a few crystals of potassium cyanide. In a mixture of methyl and ethyl alcohols (1 : 5), the fluorescence is orange-red; when this is frozen to a glass in liquid air, it exhibits a short-lived orange phosphorescence (with very dilute solutions the phosphorescence is green). We have examined other systems, not all of which show fluorescence at ordinary temperatures, but all of which emit radiations at liquid-air temperature. Our preliminary observations are recorded in the accompanying table.

| In solution in methanol/ethanol (1 : 5) | Fluorescent colour at room temperature | Phosphorescent colour at liquid-air temperature |
|---|---|---|
| Sodium nitrite/*sym*-trinitrobenzene | — | blue |
| " " /chloranil | — | blue |
| " cyanide/*o*-dinitrobenzene | green | blue-green |
| " " /*m*- " | green | pale-blue |
| " " /*p*- " | greenish-brown | green |
| " " /*sym*-trinitrotoluene | — | red (green on dilution) |
| " " /chloranil | green | blue |
| " acetate/*sym*-trinitrobenzene | orange-red | yellow-green |
| Methylamine/*sym*-trinitrobenzene | red | orange |

We believe that in these systems there is immediate complex formation, involving some donor–acceptor mechanism whereby a transition between molecular levels, originally forbidden, becomes permitted in the complex. Whether this level, distorted by the proximity of the donor molecule, corresponds to a level in the acceptor molecule or its ion, we cannot at present say.

We are grateful to Dr. E. J. Bowen for his suggestions and discussion.

*Note added in proof.* It may be mentioned that, since this letter was submitted, Reid[2] has described the emission spectra of certain hydrocarbon – aromatic nitrocompound complexes. He arrives at similar conclusions concerning the nature of the transitions involved.

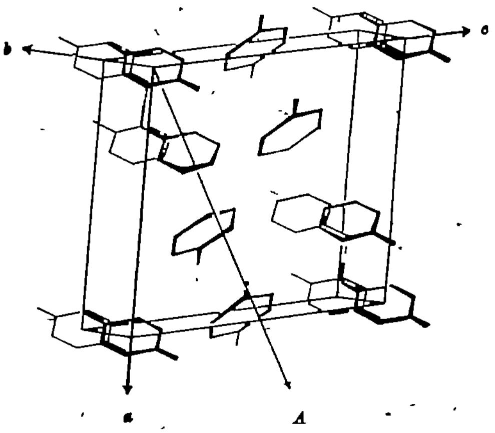
## Molecular Compounds of the Quinhydrone Type

THE nature of the molecular interaction in the formation of crystalline quinhydrones has been discussed previously by Anderson[1]. By comparison of preliminary crystallographic data for a number of quinhydrones, he came to the conclusion that the molecules are held together by the interaction of polar groups and polarizable aromatic substances, and that hydrogen-bond formation is not an essential structural feature, though it is not necessarily excluded. We have now been able to confirm these conclusions by a detailed structure determination of phenoquinone (which will be reported in full elsewhere), and by comparison with further preliminary data for quinhydrone and other molecular compounds of this type.

The arrangement of molecules in the unit cell of phenoquinone is shown in the accompanying diagram. Each quinone molecule, such as that at 000, is sandwiched between a pair of centrosymmetrically related phenol molecules, for example, those at $\frac{1}{4}$ 0 $\frac{1}{4}$ and $\frac{3}{4}$ 0 $\frac{3}{4}$. This results in the structure being built up of sets of three molecules arranged in columns parallel to the direction marked *A* in the diagram. In each set the plane of the quinone molecule is parallel to those of its two adjacent phenol molecules and is separated from them by a distance of 3·33 A. Each phenolic hydroxyl group forms a hydrogen-bond of length 2·64 A. with a quinone molecule in an adjacent column, two such hydrogen-bonds being indicated in the diagram by broken lines.



In order to compare this structure with that of quinhydrone, we must take into consideration the fact that, in the latter structure, the molecules must lie in special positions, since there are only two of each type of molecule in a cell of space-group $P2_1/c$. Further, on X-ray photographs taken with the crystal oscillating about its *a*-axis, the extremely low intensity of reflexions on layer lines of odd order indicates an almost exact repetition of the structure at intervals of $a/2$ parallel to the *a*-axis. The only choice of special positions which makes this arrangement possible necessitates the stacking of quinone and quinol molecules alternately, in continuous columns along the *a*-axis. This means that the unit cell of quinhydrone must be compared with the cell formed by the *A*-, *b*- and *c*-axes of phenoquinone as shown below.

| Quinhydrone | Phenoquinone |
|---|---|
| $a_0$ = 7·55 A. | $A_0$ = 11·62 A. |
| $b_0$ = 6·05 A. | $b_0$ = 5·97 A. |
| $c_0$ = 11·55 A. | $c_0$ = 11·48 A. |
| $\beta$ = 110° | $\beta$ = 109° |

It may be seen that there is a close similarity between the two sets of cell dimensions, except that the $a$-dimension of quinhydrone is approximately equal to two-thirds of the $A$-dimension of phenoquinone. This factor of two-thirds relating the two dimensions is to be expected in view of the change in stoichiometric composition from 1 quinone/2 phenol to 1 quinone/1 quinol. When this is taken into consideration, it follows that the arrangement and orientation of the molecules must be very similar in the two structures. It therefore appears that the essential structural feature in this type of molecular compound is the plane-to-plane stacking of alternate polarizing and polarizable molecules. Where hydrogen-bonding is possible, as in these two complexes, it must also be of importance in determining the structural arrangement, since it is to realize the full hydrogen-bonding potentialities of the molecules that the change in stoichiometric composition occurs.

In order to investigate the extent to which the principle of plane-to-plane stacking of alternate component molecules determines the structure of molecular compounds, an X-ray crystallographic survey is being made of such series of complexes as those formed by quinones and by aromatic nitro compounds. For all those so far investigated (complexes between hexamethyl-benzene and chloranil, trinitrobenzene and anthracene, trinitrobenzene and naphthalene), it has been possible to propose trial structures based on this principle. The only detailed structure determination which has so far been carried out for a molecular compound formed by trinitrobenzene, namely, with $p$-iodoaniline[2], also shows this same type of molecular arrangement.

## Simultaneous Sulphonation and Nitration in an Aromatic Nucleus

FROM the literature[1,2], when β-naphthylamine is nitrated by either: (1) the addition of potassium nitrate to a cooled solution of β-naphthylamine in concentrated sulphuric acid; or (2) the addition of β-naphthylamine nitrate to concentrated sulphuric acid, the products are 5-nitro and 8-nitro 2-naphthylamine.

If, however, β-naphthylamine is nitrated by the addition of a mixture of nitric and sulphuric acids to a solution of the amine in sulphuric acid at − 25°, or by the addition of β-naphthylamine sulphate to a mixture of nitric and sulphuric acids, the product is a mixture of two isomeric nitro aminonaphthalene sulphonic acids in the approximate ratio of 70 : 30, the main product being 1-nitro 2-aminonaphthalene 6-sulphonic acid. (The structure of the other isomer is not yet known.)

This reaction is peculiar in four respects: (*a*) it is the first case known to us of simultaneous sulphonation and nitration in an aromatic nucleus; (*b*) the main product is the result of *ortho–para* direction; (*c*) a remarkable difference in reaction mechanism is produced by comparatively small changes in experimental technique; (*d*) this anomalous behaviour is not shown by α-naphthylamine.

Details of this work will be published elsewhere.

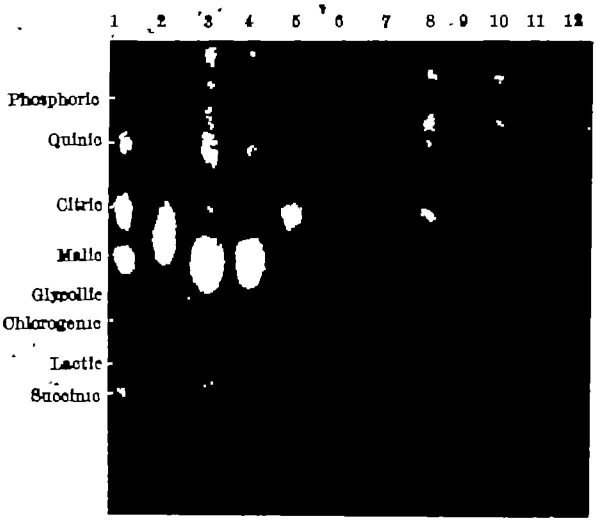
## Degradation of Sugars on Ion-Exchange Columns of 'Amberlite IRA 400 (OH′)'

IT has recently been suggested by Roseman *et al.*[1] that columns of 'Amberlite IRA 400 (OH′)' might be used for the separation of certain reducing and non-reducing carbohydrates. Our own experience with this resin suggests that very carefully controlled conditions would be necessary if reliable quantitative results are to be obtained. During an investigation of the non-volatile organic acid components of apple juice and cider, it has been found that sugars are extensively degraded by 'Amberlite IRA 400' used in the OH′ form, organic acids being the main products of degradation.

Paper chromatography was used for the separation of the acids following the technique of Lugg and Overell[2]. Interfering cations, sugars and other non-acidic materials were removed by the use of ion-exchange resins, 50-ml. samples of juice or cider being given the following treatments: (i) cation removal on 'Amberlite IR 120', (ii) anion removal on 'Amberlite IRA 400' and elution with $N$ ammonium carbonate, (iii) removal of excess ammonium carbonate by evaporation on the water-bath, and (iv) removal of remaining ammonium ions by treatment with 'Amberlite IR 120'. 10-gm. quantities of resin retained in glass tubes of 0·8 cm. diameter were used throughout with a flow-rate of 1 ml./min.

Initially, the 'IRA 400' resin was used in the OH′ form, and it was found that a number of acid spots were apparent on the chromatograms of treated samples which were not found on those of samples before treatment or after stage (i) in the above procedure (compare chromatograms 2 and 3). Malic, quinic[3], chlorogenic[4] and phosphoric acids were identified as present in the juices; ciders contained succinic acid in addition. After ion-exchange treatment, chromatograms revealed five additional spots, two being identified as due to lactic and glycollic acids. Titration of samples after stages (i) and (iv) showed that the anion-exchange treatment resulted in increases of acidity, the extent varying according to the time of contact with the resin. Increases, expressed as malic acid, ranged from 0·05 per cent (in 2 hr.) to 0·40 per cent (in 17 hr.). Solutions containing a mixture of pure acids, when subjected to the above treatments, showed no change in acidity and the chromatograms showed no additional spots.

An average cider-apple juice contains sugars in the proportions fructose 10, sucrose 2 and glucose 1·5 per cent[5]. A neutral solution of sugars of this composition was passed through a column of 'IRA 400 (OH′)', the column washed thoroughly with distilled water and



Chromatograms developed in benzyl alcohol (3 vol.), tert. butyl alcohol (1 vol.), *iso* propyl alcohol (1 vol.), water (1 vol.) and formic acid 2 per cent (see ref. 8) and run at laboratory temperature. Papers sprayed with 0·08 per cent bromo cresol green in 95 per cent aq. ethanol.

1, Standard mixture of malic, quinic, succinic, lactic and citric acids; 2, untreated cider (S.G. 1010); 3, cider-acid extract using 'IRA 400 (OH′)'; 4, cider-acid extract using 'IRA 400 ($CO_3''$)'; 5, sugar solution (fructose, glucose and sucrose) after 'IRA 400 (OH′)' treatment; 6, sugar solution (fructose, glucose and sucrose) after 'IRA 400 ($CO_3''$)' treatment; 7, untreated fructose solution; 8, fructose solution after 'IRA 400 (OH′)' treatment; 9, untreated glucose solution; 10, glucose solution after 'IRA 400 (OH′)' treatment; 11, untreated sucrose solution; 12, sucrose solution after 'IRA 400 (OH′)' treatment

left overnight (17 hr.) before elution. An increase in acidity of 0·76 per cent was recorded, and the chromatogram showed that this increase was represented by the additional acid spots previously found in treated juices (chromatogram 5).

To determine the differential effect of the treatment on these three sugars, corresponding concentrations of each sugar were submitted separately to the resin treatment, the columns being left overnight before elution. The results are summarized in the accompanying table, sugars being estimated by the method of Somogyi[6].

From the table it can be seen that (1) there is no retention of any of the three sugars by 'Amberlite IR 120', (2) all three sugars are retained by 'IRA 400 (OH′)', (3) there is considerable degradation of fructose and glucose with the production of organic acids, (4) sucrose, a non-reducing sugar, is relatively little attacked by the resin, (5) sugars which have not been degraded can be removed from the column by elution with *N* ammonium carbonate. Chromatograms 7–8, 9–10 and 11–12 show the acids produced by degradation of the sugars.

| | Weight of sugar (gm.) | | |
|---|---|---|---|
| | Fructose | Sucrose | Glucose |
| (*a*) Entering 'IRA 400 (OH′)' column (50 ml of solution) | 4·04 | 0 85 | 0·61 |
| (*b*) Present in effluent and water washings | 2·8 | 0 005 | nil |
| (*c*) Retained on 'IRA 400 (OH′)' | 1·24 | 0·845 | 0 61 |
| (*d*) Eluted by ammonium carbonate | 0·53 | 0 80 | 0·32 |
| (*e*) Present after 'IR 120' treatment (stage iv) | 0·52 | 0·80 | 0·32 |
| (*f*) Percentage of retained sugar (*c*) degraded in 17 hr. | 57·3 | 0·05 | 47·6 |
| (*g*) Acidity of final solution (50 ml.) as per cent malic | 1·055 | 0·08 | 0·60 |

By using 'Amberlite IRA 400' resin in the $CO_3''$ form, as described by Bryant and Overell[7], it is possible to obtain practically sugar-free extracts of apple juice or cider showing no increases in acidity (chromatogram 4). Very little sugar is retained by the resin and there is no degradation even after a considerable period of contact (chromatogram 6).

## Filter-Paper Disk Chromatography

As a corollary to our comparative studies of the amino-acid metabolism of bacteria[1], it was necessary to develop a simple chromatographic technique suitable for routine use in the laboratory. Such a technique using filter-paper disks was developed and fully described[2]. Recent publications in *Nature*[3,4] and elsewhere[5] describing almost identical methods would suggest that our publication has escaped notice.

Our experience with paper disk chromatography in the past three years shows that, although the method is admirable for the separation of two or three substances, it is not a satisfactory substitute for large-scale paper chromatography in the separation of more complex mixtures such as protein hydrolysates.

## Paper Partition Chromatography of Natural Œstrogens

The paper chromatography of steroids, for example, cortical steroids, has already been investigated by Zaffaroni *et al.*[1] and by Bush[2]. Although the separation on paper of the natural œstrogens free or in compounds has already been investigated by Bush[3], Heftmann[4], Nyc *et al.*[5] and Boscott[6], a satisfactory separation of the three natural steroids on non-treated paper has, to our knowledge, not yet been published. The method described below gives excellent results. It has been especially devised for separating and purifying the small amounts of œstrogens normally present in biological fluids.

The detection of quantities of œstrogens weighing about 1–5 μgm. on paper chromatograms is very successful after grinding a solution of 10 per cent antimony chloride in chloroform and heating it for 5 min. at 90–100° C. Spots of different colours are obtained with the three steroids: brown for œstrone, yellow for œstradiol and pink for œstriol. The limit of sensitivity is about a microgram. Examination under ultra-violet light increases the sensitivity of detection for œstradiol (0·2 μgm.) and œstriol (0·5 μgm.). This reaction is generally satisfactory. The spotting of œstrogens on paper can also be realized after treatment with Folin's, Pauly's and other diazo-reagents, and after drying and subjection to ammoniacal vapours. However, these diazo reactions are not so useful in practice.

One solvent—water—and the ascending method was first tried for the separation of the three phenolic steroids on paper. Because of their different dissociation constants, some alkaline solutions give different $R_F$ values for the three hormones. With $N/20$ sodium hydroxide, for example, the results obtained are 0·04–0·21 and 0·5 respectively for œstrone, œstradiol and œstriol. Organic bases also give good results (15 per cent pyridine). However, in the light of our experiments, we consider that the utilization of aqueous solvents for clear separations is not advisable when steroids exceed 20–30 μgm., because of the streaky movements. Furthermore, when mixed with biological extracts, œstrogens do not always show the same $R_F$ values as in pure solutions. In fact, the separation of œstrone from œstriol was the only one we could achieve, this being effected with $N/20$ sodium hydroxide or 33 per cent methanol.

A very satisfactory separation of the three natural œstrogens on paper can be obtained with the use of non-miscible liquids. Our method involved the use of glass cylinders (15 cm. in diameter and 40–50 cm. long) closed by means of two glass plates, and Whatman No. 1 filter paper. The descending method is normally employed. Saturation of the paper is first completed with $N/2$ ammonium hydroxide lying at the bottom of the cylinder. The most satisfactory mobile fluid found was the organic phase of a mixture of 1 part chloroform, 9 parts benzol and 1 part $N$ ammonium hydroxide. This mobile phase is introduced into the cylinder without desaturation of the atmosphere. A movement of 30 cm. on the paper takes 2–3 hr. at room temperature. The positions of the spots are observed after drying the paper by spraying it with a solution of antimony chloride in chloroform and heating at 90–100°. The $R_F$ values so obtained are, respectively, 0·89, 0·78 and 0·02 for œstrone, œstradiol and œstriol.

A similar separation is also obtainable with the same mobile phase, and methanol – water (1 : 2) being utilized for saturation of both the solvent and the atmosphere. The spots are, in this case, sharper, but the $R_F$ values for œstradiol and œstrone are closer.

If, after separation on paper, the œstrogens are to be estimated, it is advisable to cut the paper into transverse strips corresponding to their theoretical $R_F$ values. The elution of hormones is quantitative when utilizing the movement of a mixture of chloroform – acetone (1 : 1). The estimation may then be effected on the solutions by one of the known methods, especially fluorometry or polarography after nitration[7].

## Colour Reactions on Paper Chromatograms by a Dipping Technique

IN a recent communication by Hulme and Arthington[1], writing of the isatin test for proline, they state that "it is surprising that this useful test has not been more widely used". This prompts a report of further advantages of this reagent and a description of a general technique which has been in use in this laboratory for some months.

In all experiments, 5 μl. of solution containing 0·01 $M$ pure amino-acid or a synthetic mixture of twenty amino-acids all in the same concentration was used. Normal and pathological urine was also tested. One- and two-dimensional chromatograms were prepared in phenol/ammonia or butanol/acetic acid on papers 10 in. square, mounted in Datta frames[2]. After thorough removal of the solvent in a cold-air draught, the papers were drawn through a 0·2 per cent solution of recrystallized isatin in acetone contained in a shallow 'Pyrex' dish. As soon as the acetone had evaporated from the paper, it was heated for 2 min. at 105° C. or for 15 min. at 65° C., when proline and hydroxyproline produced the usual blue colour. In addition, cystine and often tyrosine appear blue; aspartic and glutamic acids, initially pink, assume a blue tinge; tryptophane appears rose-red (as stated by Hulme and Arthington); and many other amino-acids, especially glycine, appear deep pink, although these pinks tend to fade. The comparison of this method with those of Hulme and Arthington and of Acher, Fromageot and Jutisz[3] is very favourable both with respect to depth and stability of colour and the number of amino-acids located.

Many substituted isatins, kindly supplied by Dr. S. J. Holt, have been tested. The N-methyl-, 6-Cl-, 7-Cl-, 5-methyl- and 5 : 7-dimethyl-isatins all give colours similar to isatin (but none of these justifies the replacement of isatin). The 6 : 7-dimethoxy, 4-Cl-, 7-COOH- and N-acetyl-isatins, 4 : 5-benzisatin and 5 : 5′-di-isatyl are negative.

The advantages of this dipping technique are that the amino-acids are insoluble in acetone and therefore do not spread, the paper dries in 1–2 min., there is no offensive smell (compare butanol or solvents containing 1 per cent collidine or pyridine) and the colours are generally deeper. The method is economical and the use of an expensive spray gun or tiresome and fragile handspray is eliminated.

Ninhydrin, as 0·2 per cent solution in acetone, is at least as satisfactory when applied by dipping as by the conventional spray technique. The colours develop after 1–2 min. at 105° C. or in 2–4 hr. in the cold. After this method had been in use for some time, it was noted that Toennies[4] had recommended the same method.

Dipping in Ehrlich's reagent, *p*-dimethylaminobenzaldehyde, prepared fresh as a 1 per cent solution in a mixture of nine volumes of acetone to one volume of concentrated hydrochloric acid, gives the usual purple tryptophane colour within two minutes in the cold, deepening on standing. This compares favourably with the method of Dalgliesh[5], which takes two hours for tryptophane to appear. In general, the method is quicker for many of the amino-acids and amines listed by Dalgliesh.

Although this technique was developed for my own work on amino-acids, it is particularly valuable for student use, especially where speed in development (as for tryptophane) is a great advantage.

The technique has only been applied to amino-acids; but I believe that it would be equally valuable for many other classes of compound which are insoluble in acetone, ether or other volatile solvents. In addition, the method should be of value for spot-test reactions on paper, as these are often more sensitive than those carried out in the test-tube.

I wish to thank Dr. J. B. Jepson for his help and encouragement.

## Elastin and Elastase

In previous publications[1,2], we reported that extracts of animal pancreas made with fluids of different *p*H exhibit varying elastolytic activity (e.u./gm.) on account of the presence of elastase inhibitor, which in the pancreas is bound to elastase[3]. In crude neutral solution, the activation of elastase may be carried out by acidification, dialysis or precipitation with ammonium sulphate[1,3]. In all these procedures the elastase is being liberated from elastase-inhibitor. It has been pointed out by us that two types of elastase-inhibitor exist, namely, one in the pancreas and another in the blood serum[4]. Whereas that from the pancreas dialyses in 24–32 hr. and can be demonstrated in the dialysate, that from the serum cannot be dialysed.

We determined the elastase content of the pancreas of healthy young men who had died suddenly in consequence of accidents and compared the value obtained with the elastolytic activity found in the pancreas of men who had died of various diseases or had had arteriosclerosis[4]. Extracts were prepared from each human pancreas using the following methods: (1) fresh pancreas extracted with a double volume of *N*/10 acetate buffer of *p*H 4·7; (2) same as (1), with subsequent dialysation for 24 hr.; (3) extract of degreased pancreas powder prepared as (1) but with a five-fold volume of buffer; (4) same as (3), with subsequent dialysation for 24 hr.

We found that the pancreas of young healthy individuals (group 1, 10 cases) contained 208 ± 56 e.u./gm. The pancreas of those who had died of various diseases without arteriosclerosis (group 2, 14 cases) contained 155 ± 49 e.u./gm., whereas the pancreas of men who had had arteriosclerosis (group 3, 36 cases) yielded 9 ± 6·5 e.u./gm. Comparing the values of either group 1 or group 2 with group 3, the differences are significant. In 54 per cent of the cases of group 3, elastase could not be detected in the pancreas at all. Hall, Reed and Tunbridge[5] were not able to obtain elastase from human pancreas. This can be explained only by supposing that they disregarded the elastase inhibitor of the pancreas, the presence of which makes it impossible to demonstrate elastase without activation in sodium chloride or water extracts. Another possibility would be that they examined only human pancreas which contained no elastase. In the pancreas of men above the age of forty elastase is often lacking. Contrary to the finding of Hall, Reed and Tunbridge, however, we find that the pancreas of healthy men contains elastase, as has already been reported in our first publication[6].

Banga and Schuler[7] found that, following the action of elastase upon elastin, carbohydrate is liberated. This is in accordance with the finding of Hall, Reed and Tunbridge. The only difference is in the quantity of carbohydrate found. According to our results, as a consequence of elastolysis 10–12 per cent of carbohydrate is liberated from the elastin of Stein and Miller as well as from the elastins of both Gross and Banga. Hall, Reed and Tunbridge obtained from the aorta 2 per cent polysaccharide only. By the orcin method of Rimington[8] only a small part of the carbohydrate can be estimated, whereas the whole quantity can be determined by titration with hypoiodide or by the method of Hagedorn–Jensen. The elastin dissolved with elastase reduces ferric to ferrous iron in the cold and decolorizes dichlorophenolindophenol when heated. Molisch and Seliwanoff tests are negative. The carbohydrate liberated during dissolution of elastin resembles, in its reducing properties, glucosamine, since it cannot be estimated by the orcin method of Rimington and it does not give either the Molisch or Seliwanoff tests.

## Effect of Acetoacetate on Glycogen Synthesis and Glucose Utilization in the Isolated Rat Diaphragm

The effect of ketone bodies on carbohydrate metabolism is still obscure, and several theories have been proposed to explain their action[1-3]. Nagler[4] incubated surviving rat diaphragm in phosphate buffer medium containing glucose (200 mgm. per cent), glucose and insulin (0·05 unit per 1·0 ml.), glucose, insulin and acetoacetate (50 mgm. per cent). No effect of acetoacetate on glycogen synthesis was observed. Parnes and Wertheimer[5] reported that acetoacetate depressed glycogen synthesis in the rat diaphragm, thus differing from other metabolites.

In the present experiments, we have extended the studies of Nagler and of Parnes and Wertheimer. Diaphragms of rats fasted for one day were incubated in phosphate buffer solution containing 50–100 mgm. per cent glucose. The addition of 100 mgm. per cent acetoacetate to the medium decreased glycogen synthesis and increased glucose utilization. These effects were highly significant when the medium contained 50 mgm. per cent glucose, and also significant in the presence of 100 mgm. per cent. Other products such as acetate, pyruvate and acetone were without effect.

The specific action of acetoacetate was influenced by the proportions of glucose to acetoacetate as shown in Table 1. An increase of the glucose concentration prevented the acetoacetate effect.

Table 1. EFFECT OF VARYING GLUCOSE CONCENTRATIONS IN THE PRESENCE OF ACETOACETATE ON GLYCOGEN SYNTHESIS AND GLUCOSE UTILIZATION

Diaphragms were incubated at 37° C. for 2½ hr. Glycogen synthesis and glucose utilization expressed as mgm. glucose per 100 mgm. wet tissue

| No. of experiments | Medium containing | | Glycogen synthesis (mgm./100 mgm.) | Glucose utilization (mgm./100 mgm.) |
|---|---|---|---|---|
| | glucose (mgm. per cent) | aceto-acetate (mgm. per cent) | | |
| 7 | 50 | — | 0·098±0·020 | 0·30±0·03 |
| 7 | 50 | 100 | −0·007±0·008 | 0·44±0·04 |
| 12 | 100 | — | 0·143±0·014 | 0·48±0·05 |
| 12 | 100 | 100 | 0·042±0·007 | 0·63±0·07 |
| 5 | 200 | — | 0·184±0·030 | 0·75±0·03 |
| 5 | 200 | 100 | 0·172±0·014 | 0·78±0·04 |

The results shown in Table 1 explain the results obtained by Nagler[4].

Addition of insulin to a medium containing glucose increased the glycogen synthesis and glucose utilization by the rat diaphragm, as was first described by Gemmill[6]. Addition of insulin to a medium containing glucose and acetoacetate caused a smaller increase, as illustrated in Table 2.

Table 2. EFFECT OF ACETOACETATE IN GLUCOSE AND GLUCOSE + INSULIN MEDIA

Diaphragms incubated at 37° C. for 2½ hr. Glucose concentration, 100 mgm. per cent; acetoacetate concentration, 100 mgm. per cent; insulin, 0·1 unit per 1·0 ml. Glycogen synthesis and glucose utilization expressed as mgm. glucose per 100 mgm. wet tissue

| No. of experiments | Samples incubated | Difference in | |
|---|---|---|---|
| | | Glycogen synthesis (mgm./100 mgm.) | Glucose utilization (mgm./100 mgm.) |
| 7 | Glucose with and without insulin | +0·123±0·018 | +0·51±0·010 |
| 9 | Glucose and aceto-acetate with and without insulin | +0·078±0·018 | +0·41±0·006 |

Results similar to those shown in Table 1 were observed in diaphragms of mildly diabetic rats (blood-sugar level, 100–300 mgm. per cent); but acetoacetate had no effect on the diaphragms of severely diabetic rats (blood-glucose level, 400 mgm. per cent or higher, acetonuria), of rats in diabetic coma, and of rats fasted for five to seven days. The latter group of fasted rats lost 35–40 per cent of their initial weight and were in poor condition.

A single intraperitoneal injection of 100 mgm. acetoacetate per 100 gm. body-weight was given to normal rats. Acetate or saline was administered to controls. 1–3 hr. after injection of these compounds, the animals were bled and their diaphragms incubated in a phosphate buffer medium containing 100 mgm. per cent glucose.

The injected acetoacetate depressed glycogen synthesis in the incubated diaphragms. Acetate and saline were without effect. Acetoacetate[3] as well as acetate caused hypoglycæmia and increased alkalosis. Acetoacetate increased acetone bodies in the blood to 10 mgm. per cent (controls, 4·5 mgm. per cent) 2 hr. after injection. These *in vivo* results were thus similar to those obtained *in vitro* by addition of acetoacetate to the incubating medium. They were due solely to the injection of acetoacetate, and did not appear after acetate or saline administration.

It is concluded that acetoacetate has both an *in vitro* and an *in vivo* influence on carbohydrate metabolism in muscle. The depression of glycogen synthesis by acetoacetate is demonstrable also in the presence of insulin.

## Effect of L-Glutamic Acid Analogues on the Enzymatic Formation of Hydroxamic Acid

AQUEOUS extracts of acetone-dried sheep brain form hydroxamic acid from L-glutamic acid and hydroxylamine in the presence of adenosine triphosphate[1]. It was found that this reaction is inhibited by DL-N-(γ-glutamyl)-ethanolamine. Molar ratios of DL-N-(γ-glutamyl)-ethanolamine to L-glutamic acid varying from 2 : 1 to 10 : 1 gave inhibitions of 10–50 per cent. On the other hand, DL-α-methylglutamic acid not only did not inhibit the reaction between L-glutamic acid and hydroxylamine, but could be substituted for glutamic acid in this reaction, apparently with the formation of α-methylglutamohydroxamic acid.

The sheep brain transferase system[2] which forms glutamohydroxamic acid from hydroxylamine and L-glutamine is not affected by DL-N-(γ-glutamyl)-ethanolamine but is inhibited by DL-α-methylglutamic acid as well as by D-glutamic acid. Molar ratios of DL-α-methylglutamic acid to L-glutamine varying from 2 : 1 to 20 : 1 gave inhibitions of 25–70 per cent; whereas molar ratios of D-glutamic acid to L-glutamine varying from 1·25 : 1 to 5 : 1 gave inhibitions of 25–45 per cent.

Both the synthesizing and the transferring reaction were measured by estimation of the hydroxamic acid formed. The synthesizing reaction was also measured by estimating the inorganic phosphate liberated from adenosine triphosphate.

When in the synthesizing reaction between DL-α-methylglutamic acid and hydroxylamine the latter was replaced by ammonia, free phosphate was also liberated from adenosine triphosphate. Evidence indicating the formation of α-methylglutamine was obtained by use of paper chromatography.

An inhibition of the synthesis of glutamohydroxamic acid from glutamic acid and hydroxylamine by DL-N-(γ-glutamyl)-ethanolamine was also obtained with dialysed extracts of acetone-dried pigeon livers prepared according to Speck[3]. These extracts also formed a hydroxamic acid from hydroxylamine and DL-α-methylglutamic acid.

An inhibition of both the synthesizing system and the transferase system by methionine sulphoximine has recently been described by Pace and McDermott[4].

This investigation was supported in part by a grant from the Rockefeller Foundation.

## Non-Effect of Hyaluronidase on the Spread of Œstrone

Since it is known that hyaluronidase increases the spread of certain substances in the skin of mammals by increasing the permeability of the dermis[1], it appeared possible that this enzyme might affect the spread of œstrone where this can be shown to be localized in the dermis.

The administration of œstrone to Brown Leghorn capons changes the colour of developing feathers from black to rust. If a small amount of œstrone in 60 per cent alcohol is injected intradermally, such an effect may continue for some days and is mainly produced in the vicinity of the injection[2], although feathers developing in other parts of the body may also react. It may be supposed, therefore, that while some of the hormone is carried away, some remains available near the site of the injection and is responsible for a localized reaction.

It is possible that such results are explained by the fact that the œstrone was injected in alcohol, since it is now known that, although alcohol penetrates the dermal barrier freely at first, the area of spread is afterwards limited by skin coagulation which follows[3]. Nevertheless, it was thought worth while to see if this partial localization of the effect of injected œstrone was affected by hyaluronidase.

Intradermal injections of œstrone with and without hyaluronidase were made in plucked patches where feathers were regenerating on the breasts of Brown Leghorn capons. These injections also contained hæmoglobin prepared from fresh sheep's blood, since the degree of spread of hæmoglobin is an accepted method of assay of hyaluronidase. Since œstrone is only very sparingly soluble in water and hæmoglobin coagulates in strong alcohol, it was found convenient to use a mixture of hæmoglobin and œstrone in 40 per cent alcohol. Doses of 0·1 ml. were given, and the concentrations were so arranged that each dose contained 0·05 mgm. of œstrone, or, in a few cases, half this. Similar mixtures, in similar doses, were used in the experimental series, but with the addition of hyaluronidase equal to the œstrone in weight. In each experiment each capon received two injections at intervals of a week. After three months, the feathers were plucked and filed.

When hyaluronidase was included in the injection, its presence was shown by an immediately increased rate of spread of hæmoglobin. The area of subsequent spread of hæmoglobin was recorded on plots of the feather patches approximately six hours after the injection. Fifty-four injections were made, half of which contained hyaluronidase: of these, seventeen gave an increased spread in six hours; in seven cases this spread was not markedly increased, and in three it was reduced as compared with the controls.

On the other hand, the inclusion of the enzyme was not associated with any significant change in the following measurements made on the plucked feathers: (1) the area of the largest rust-coloured mark on any feather in the patch; (2) the length of the longest rachis mark; (3) the average area of mark per affected feather; (4) the average length of rachis mark per affected feather; (5) the total affected area of feather; (6) the percentage of surviving feathers affected. These results were obtained from experiments on six birds, in which it was possible to make fifteen strict comparisons between marks caused by œstrone with and without hyaluronidase.

These results seem to indicate that, although the rate of spread of the hæmoglobin is affected, the spread of œstrone is not affected by hyaluronidase. It is, however, possible that the interstitial pressure did not remain sufficiently high for the hyaluronidase to affect the ultimate spread of the injection. It has been shown that, in an intradermal injection, hyaluronidase only acts if there is local increase of interstitial pressure produced by the injection. As the injected fluid spreads, the bleb pressure diminishes until it is equal to the normal interstitial pressure of the skin. At this point excess hyaluronidase no longer affects spreading[4]. In our experiments we found that the rate of spread of hæmoglobin was initially increased, but we do not know whether the ultimate area of spread was affected, as the indicator became too indistinct to be measured.

In further work to test whether hyaluronidase affected a non-local reaction, spayed female mice were implanted with a crystal of œstrone in the neck and half of them received in addition dry hyaluronidase. The hyaluronidase is probably rapidly dissolved in the body fluids. By this means any complications which might have arisen from the use of any solvent or vehicle were eliminated[5], although the possible different states of the crystals used may be a ground for criticism of this method. The results seemed to indicate that the enzyme did not affect the rate of uptake of œstrone by the animal as measured by the time of onset or by the rate of thickening of the vaginal epithelium. In another series, hyaluronidase dissolved in water was repeatedly injected subcutaneously following implantation of œstrone crystals as above. Once more, no significant effect of the enzyme could be found.

Although this work is not regarded as complete or conclusive, it appears that in the mouse the uptake of œstrone is controlled by some mechanism less easily disturbed by hyaluronidase than is, for example, the mechanism which controls the uptake of such substances as are used medically in hypodermoclysis[6].

This work was done during the tenure by one of us (M. E. B.) of a research award of University College, Hull.

## Seasonal Fluctuations in the Degree of Hatching from Cysts of the Potato Root Eelworm

THE rate of hatching of larvæ from cysts of the potato root eelworm *H. rostochiensis* Woll. during *in vitro* hatching tests has been found by many workers to show seasonal fluctuations, a high level of larval emergence during the summer months declining to a negligible hatch during the winter.

After a series of experiments to measure this fluctuation quantitatively, Lownsbery concludes[1] that the phenomenon is inherent in the physiology of the worm and is not correlated with any seasonal difference in the leachings used. He agrees with Reinmuth[2] that exposure to winter conditions is not necessary for the induction of the dormant period. His attempts to break the dormancy by temperature and humidity control were unsuccessful. The phenomenon of winter dormancy was also demonstrated by Triffitt[3].

We have been conducting *in vitro* hatching tests for a number of years, and now wish to record that for the past three years we have not found any apparent diminution in the 'hatchability' of the cysts during the winter months. Cysts floated from soil collected during the spring and summer months are rolled from the debris and stored in small bottles or large tubes in a dark cupboard at room temperature. The corks are notched at one side to allow free air circulation. No attempt is made to maintain a uniform temperature; the normal fluctuations in room temperature appear to have no harmful effect provided the temperature does not fall below about 15° C. The root diffusate used in all the hatching tests is collected during the summer, pooled, mixed and then stored at about 3°–4° C. When setting up a hatching test, the cysts are weighed into batches on a micro-balance[4] and soaked in tap water for about fourteen days. Afterwards, the water is removed and root diffusate added, when normal hatching occurs.

Our experience indicates that *Heterodera* cysts are not essentially subject to a winter dormancy. The low hatches during the winter months encountered by other workers probably result from the influence of external environment, possibly soil conditions at the time of cyst extraction. This view is supported by the fact that cysts washed from soil taken from fields in late autumn or winter show an apparent dormancy, whereas cysts recovered from the above soil during the summer and stored under the same conditions do not. The apparent dormancy encountered cannot be of so fundamental a nature as suggested by Lownsbery[1], since cysts recovered from soil and stored under the conditions described above are capable of hatching at the normal rate throughout the winter months.

## Experimental Induction of Male Cones in *Pinus sylvestris*

IT is well known that seedling trees of *Pinus sylvestris*, in common with those of many other woody species, pass through a juvenile period, during which no reproductive organs are formed. The first female cones appear at the age of about seven years, while male cones are not usually formed until several years later. These male cones generally appear first on the lower, older branches.

In 1950, I observed that certain trees of about twelve years of age growing in plantation at Oxshott Common, Surrey, bore numerous female cones; but none of the trees showed branches which had passed to the male condition. Closer inspection revealed a few isolated male shoots, however, and in every case these were borne on vegetative shoots of which the terminal bud had failed to develop in the previous season, due to attack by an insect (the identity of which has not yet been determined). As a result of this destruction of the terminal bud, the uppermost 'dwarf shoots' (bearing paired needles) had been stimulated to produce a resting bud, and it was in such buds that male cones had developed. I have since observed similar examples on several occasions in various localities.

In order to test whether experimental removal of the terminal buds would have the same effect, a considerable number of shoots on the lower branches of ten of the trees in question were disbudded by hand in January 1951. One or two of the uppermost dwarf shoots on each treated shoot developed resting buds during the summer of 1951, and these unfolded in the spring of 1952. Inspection in May 1952 revealed that 242 out of a total 472 treated shoots (that is, 53 per cent) had developed male shoots, and these were the only ones present on the trees in question (apart from a few isolated male cones again found to be associated with insect-destruction of the normal terminal bud). In some branches, 100 per cent of the treated shoots had produced male shoots.

Thus, experimental disbudding may be used for hastening the production of male cones in young trees of *P. sylvestris* and might prove a valuable addition to the other techniques, such as bark ringing and strangulation, already used in forest tree breeding.

The results of the present experiments correspond in certain respects with the experimental induction of lateral flower buds in the Haden mango by removal of the terminal bud[1].

### Saturday, January 10

British Psychological Society (in the Sharpe Theatre, Department of Psychology, University College, Gower Street, London, W.C.1), at 2.30 p m.—Dr. Leonard C. T. Jones . "Frustration and Unreasonable Behaviour" ; Miss S. K. Madan : "An Interviewing Technique involving Projection from the Tactile Kinaesthetic Modalities".

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned .

Assistant (Grade B) in Chemistry (with good honours degree) at the Brighton Technical College—The Education Officer, 54 Old Steine, Brighton 1 (January 10).

Nutrition Officer (with an honours degree in biochemistry or physiology) to take part in work that will include the determination of the biological value of proteins, the study of calcium and phosphorus metabolism using radioactive tracers, vitamin D assays, and general nutritional experiments with rats—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 52/14 (January 10).

Demonstrator in Chemical Pathology—The Registrar, The University, Leeds 2 (January 12).

Engineering and Physics Graduates to join a group working on non-linear servomechanisms and controls—The Secretary, Engineering Laboratory, Trumpington Street, Cambridge (January 15).

Principal—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (January 16).

Biochemist at the Institute of Medical and Veterinary Science, Adelaide, to be responsible for all the routine work of the biochemistry division of the Institute, and also to have charge of the clinical biochemistry department of the Royal Adelaide Hospital—The Agent-General for South Australia, South Australia House, Marble Arch, London, W.1 (January 17)

Principal Scientific Officers and Senior Scientific Officers for research and development work associated with the testing and performance of guided missiles, Senior Experimental Officers and Experimental Officers (Grade 3) to be responsible for the detailed inspection of the work of sections engaged in the experimental or engineering aspects of guided weapons research and development, at the Long Range Weapons Establishment, Salisbury, Australia—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1 (January 17).

Lecturer or Assistant Lecturer in Economic Statistics—The Registrar, The University, Manchester 13 (January 20).

Scientist, Grade I (physical chemist or chemical engineer, with not less than a second-class honours degree) to supervise the design and operation of pilot plants—The National Coal Board, Central Research Establishment, Stoke Orchard, Cheltenham, endorsed TT/577 (January 26).

Readership in Human Physiology at St. Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 9).

I.C.I Research Fellowships in Physics, Chemistry, Engineering, Metallurgy, Pharmacology, or any related subject—The Registrar, The University, Liverpool (March 1).

Beit Memorial Fellowships for Medical Research—The Secretary, Beit Memorial Fellowships for Medical Research, Lister Institute, Chelsea Bridge Road, London, S W.1 (April 14).

Agricultural Officer (with a degree in agriculture, and, preferably, training in pasture management and soil conservation), Bechuanaland Protectorate—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.63/76/01.

Demonstrator in Botany—The Registrar, The University, Nottingham.

Deputy Head of the Department of Aircraft Propulsion—The Registrar, College of Aeronautics, Cranfield, Bletchley, Bucks.

Electrical Engineer or Physicist at the Royal Aircraft Establishment, Farnborough, to undertake experimental work on design of fuses for bombs and guided weapons—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.474/52A.

Engineer in the Ministry of Supply, London, for locating, assessing and developing capacity for pilot manufacture of electronic assemblies and components—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.500/52A.

Research Physicist—The Director, M.R.C. Radiobiological Research Unit, Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Scientific Officer, Grade I (a good degree in science, engineering or mathematics is essential) in the Engineering Laboratory at Derby—The Director of Research, Railway Executive, 222 Marylebone Road, London, N.W.1.

Senior Scientific Officer or Scientific Officer (with first- or second-class honours degree in inorganic or physical chemistry) at the Water Pollution Research Laboratory, Watford, for research on the rates, under different conditions, of reactions occurring in the polluted Thames estuary including reduction of sulphate and oxidation of sulphide—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London S.W.1, quoting F.697/52A.

# SOCIAL ADJUSTMENT IN THE MODERN STATE

IN his presidential address to the British Association at Blackpool in 1936, Lord Stamp urged that society should seek consciously to regulate the rate of change resulting from technological development to an optimum point in the net balance between gain and damage to society as a whole. Lord Stamp firmly believed in the possibility of a science of social adjustment, once we had accepted Whitehead's dictum that we are living in the first period of human history for which we can no longer assume that each generation will live substantially amid the conditions governing the lives of its fathers, and transmit those conditions to the succeeding generation. Moreover, in this address, as in his later book, "The Science of Social Adjustment", Lord Stamp fixed his gaze particularly on the human aspects of the problem of adjustment and the need for ordered knowledge and principles in such varied fields as production, industrial health and ethics.

That plea has found strong support since in the writings of Elton Mayo and Chester I. Barnard and others, and it is recalled by a book which has recently come from the British Institute of Management*. The three studies, by J. F. Scott and R. P. Lynton, of the Institute's Field Research Group, in this book, of a colliery, a village factory and a large hosiery factory, and the research method which they outline and discuss in an appendix, seem to express exactly the approach for which Lord Stamp pleaded. The book is both a tribute to the value and potentialities of the British Management Institute and a valuable contribution to the technique and philosophy of social adjustment on which it is becoming clear the future of the social security State largely depends. The critical account of research method is possibly the section of most direct interest to the man of science, and this alone should contribute to a sound appreciation of both the limitations and the value of social science, not merely in management but also in social problems and human relations generally.

The wide appeal and relevance of these three studies is most apparent, however, in the second part of the book, in which a comparative interpretation of the three studies is attempted and tentative generalizations are made on the broad issues of organization, communication, control, and especially on the process and means of continued adaptation. The bearing of the observations recorded, not merely on industrial relations, but also over a far wider field, is unmistakable; and perhaps the outstanding feature is not so much the complexity of the relations studied as the evidence provided that people are not unnaturally resistant to co-operation, change or adaptation once full account is taken of their interrelationship and the full situation. In contrast to the depressing picture of ossification revealed by such studies as that of Dr. Goldstein and some by the Acton Society Trust, we are given a picture of adaptability and of willingness to work and to co-operate which holds real promise for the economic future of Britain.

---

* Three Studies in Management. By Jerome F. Scott and R. P. Lynton. Pp. x+220. (London: Routledge and Kegan Paul, Ltd., 1952.) 18s. net.

As has been said many times already, by Elton Mayo and others, industry, and especially industrial change, must be considered in the context of the society in which it exists. The complex, but informal, relations between those working together in an industry and the surrounding community constitute a social structure which cannot be disregarded in technical development and change. Should this structure be ignored, the industrial community loses its stability and sense of security. Social sickness develops, finding expression in absenteeism, inefficiency, and resistance to further change; and such social sickness must be cured before the industry can become strong and efficient, or the community secure and confident.

Evidence has already been provided by the Acton Society Trust of the difficulties caused by the careless disturbance of the old social structure by nationalization. The study described here of the pattern at a Scottish colliery shows how profound has been the disturbance of the miners' own ways of living and working together, and the social disintegration that nationalization and technical advance can cause, however unwittingly. What was once a highly flexible organization is steadily becoming more rigid, and the problem of adaptation becomes still more acute.

Even here, some attempt has been made to reconcile new methods with the old ways, and the encouragement of team-working at Bolsover is cited as example. The difficulty goes far deeper than the question of effective communications, joint consultation or of training and promotion, although the observations recorded by Mr. Scott and Mr. Lynton largely support the findings of the Acton Society Trust on these points. No formal alternatives exist to the re-establishment of good informal relationships, and the first concern of those involved in questions of productivity and efficiency in the nationalized industries—with all that those factors mean in Britain's economic future—should be to secure the conditions in which such relations can be fostered and developed spontaneously and undisturbed by political controversy.

In regard to the mining industry in Britain, the study points rather to the negative effect of the disruption of informal relations. In the other two studies—of the introduction of a new factory for finishing hosiery in a northern mining town without previous experience of industrial employment for women, and of the adaptation to post-war changes of the firmly established social structure in a large hosiery factory—positive evidence is given of the value of careful attention to that social structure. On one hand, it proved possible both to integrate the factory with the mining community and to carry the existing social structure into the factory; and on the other, to make the necessary changes without disrupting the accepted structure.

Too much stress clearly should not be laid on these two examples. The interest of the studies lies rather in the demonstration of what is possible by the use of appropriate methods. Experience doubtless will lead to the development of improved methods in time, if only as Mr. Scott and Mr. Lynton here urge, like J. T. MacCurdy ten years earlier, we take informal organizations seriously. Even specialization, they point out, is not necessarily a source of difficulty, provided it is kept in balance, and spontaneous processes are helped to adapt themselves to changing requirements. What is required above all is not so much that there should be no disturbance of balance as that a new balance should be achieved wherever the old is destroyed or disturbed. The question of size or functional specialization has to be considered and decided not on purely theoretical grounds, but on the practical issue of the effect on the balance between a works and its environment.

The first consideration is that a community should be a well-balanced, coherent social unit in which people work as well as play and live; this consideration is too frequently ignored, even though few factories can be so closely bound up with the surrounding society as a mine. None the less, they are all social institutions as well as industrial units, and Mr. Scott and Mr. Lynton are fully aware of the bearing of this consideration on town planning and the location or dispersal of industry. The response described in these two studies to efforts made to understand and foster existing relations in the community, to explain the reasons for change and to avoid adverse effects on status, shows that co-operation can be secured and change accepted without opposition.

On such evidence it is worth while taking time and making the effort to release the forces that make for co-operation, keenness to work, and adaptability. Nor is it simply a matter of education and improved means of communication, so that those affected can both understand the reason for a decision and feel that they participate in it: it involves searching demands on management to ensure that the implications and ramifications are worked out and assessed as the change proceeds, and that attention is paid to the social costs as well as to the material or economic costs. Above all, there must be consideration for the balance of security in his relations with others which a man requires if he is to remain adaptable and to accept change.

The emphasis placed on this last factor is the more important because in these studies no countenance is given to the illusion that security itself is an objective. The argument here is for security in the process of change; a disposition favourable to change arises from confidence that the change is necessary, and that the change and the methods by which it is carried out are really beneficial. The real task of management is to help the organization as a whole to perceive the need for adaptation and to adapt itself accordingly. The value of those studies, it may be reiterated, lies especially in the demonstration, not merely to industry, but also to the politician and government administrator, that, however drastically circumstances may change, there are still ways by which an organization may adapt itself rapidly in a civilized and efficient manner. The task of government, as well as of management, is to discover these ways and foster their use.

The optimism which these three studies encourage is supported by the trend of the discussion on the manager and the worker which took place at the Present Question Conference on Freedom and Responsibility. Both the Earl of Verulam, speaking on the manager, and Mr. A. E. Carthy, of the International Department of the Trades Union Congress, speaking on the worker, recognized that industry must take its part in the life of the community, and that industry must be built up in close and happy and fruitful relation with the outside world. Lord Verulam stressed first the responsibility of the manager for making his organization human, and for fostering the right atmosphere as well as the opportunity for achievement and for service to the community. Mr. Carthy no less clearly insisted on the social responsibilities of industry, and on the need for trades unions themselves to accept those responsibilities and to seek to train their members in social responsibility. Those who address themselves to the immense task of the education required to remove misunderstandings and old prejudices, or to the discovery, in any particular social or industrial context, of the vital informal pattern of human relations and to base their policy and actions thereon, need not despair of response. Nor need the trades unions themselves fear to take up the heavy task of modifying and adapting the archaic fossilized structure so powerfully indicted in recent books by Dr. J. Goldstein and by Mr. Alan Flanders, to enable the unions to meet the needs of an industrial or technical age.

## SOME FUTURE PROBLEMS IN AVIATION MEDICINE

**Physics and Medicine of the Upper Atmosphere**
A Study of the Aeropause. Editors: Dr. Clayton S. White and Brig.-General Otis O. Benson, Jr. The Proceedings of a Symposium on the Physics and Medicine of the Upper Atmosphere held at San Antonio, Texas, November 6, 7, 8, 9, 1951, sponsored by the Air University School of Aviation Medicine, Randolph Field, Texas; arranged by the Lovelace Foundation for Medical Education and Research, Albuquerque. Pp. xxiv+611+46 plates. (Albuquerque: University of New Mexico Press, 1952.) 10 dollars.

THE recognition of aviation medicine as a subject for special study and research dates from the First World War, when much attention was given to methods of selection of men suitable for flying duties. But the literature contains much of earlier origin: for example, observations on the physiological effects of atmospheric pressure change during balloon flights, sea-diving and mountaineering; and even Robert Boyle's account, published in 1670, of his experiments on animals under reduced pressure.

Although a great deal of work must always be devoted to methods of personnel selection, the bias has been tending to shift for some time. Modern aircraft impose conditions well beyond the extremes which even the fittest occupants can withstand; considerable research is necessary to reduce the full impact of these conditions; and the scope of this research advances step by step with aircraft performance. The book under review is based upon a symposium gathered to survey a wider field of knowledge than is ordinarily regarded at present as forming the territory of aviation medicine. Its aim was "the collection of available open data to provide much of the information essential to planning future research necessary for manned flight towards the top of the atmosphere". The result has been to bring more clearly into focus some of the problems which will arise when attempting to ensure health and safety, not only in the aircraft of the future, but also in man-carrying rockets and artificial satellites, and even in attempts at interplanetary travel. When some of these developments will take place is still uncertain, but something of their inevitability is conveyed by one contributor, H. Strughold, who, in a passage which appeals to the imagination, states: "The conquest of the outskirts of the atmosphere, and eventually space, is a revolutionary event comparable only to the transition of the aquatic animals to the land in geological times. . . . We are in the amphibian stage now".

There are articles contributed by thirty-four scientific workers, specialists in the topics discussed. It is not possible to reproduce the list of titles in full, but the subject-matter includes: the physics and chemistry of the upper atmosphere; the radiations occurring therein, including X- and ultra-violet radiations of solar origin and cosmic rays; the biological effects of these radiations; dangers from meteorites; temperature extremes encountered in high-altitude and high-speed flight, and protection therefrom; the effects of acceleration, and of 'weightlessness'; preservation of health during prolonged occupation of a sealed cabin; and ability to survive high-altitude conditions in emergencies, such as after cabin puncture or 'bail-out'.

Some of the apparatus, including rockets and balloons, which forms the equipment for ultra-high altitude research is also described briefly. Many of the problems mentioned could be further investigated only with such equipment, but it is pointed out that the steadily increasing range of artificially produced radiations arising from developments in particle accelerators may enable some of the relevant experiments on biological material to be performed at ground-level.

With such an unusual book as this, no very definite stipulations can be made as to what it should or should not contain. It is sufficient to say that there are some very readable articles which will provide useful introductions to more detailed study. Readers whose interests lie particularly in aviation or aviation medicine will surely find much food for thought. Also, anyone with more general interests, browsing at random, will discover a variety of information. For example, the correct procedure to be followed on finding a freshly fallen meteorite is probably not widely known and is described by L. Lapaz. Not only should all evidence facilitating an estimate of the angle and velocity of impact be preserved, but also the meteorite should be made available within a few hours at most to the nearest laboratory for autoradiographic and other tests for radioactivity. The precise importance of such tests is apparently the subject of some controversy; however, being performed on a sample of matter from space, they might lead to further knowledge of cosmic radiation, particularly regarding its potency in inducing radioactivity in exposed material.

The overlapping which is so often a fault with publications of this type seems very largely to have been avoided. It should perhaps be mentioned that the word "aeropause" is defined by its originator (K. J. K. Buettner) "as that atmospheric range in which the functions of the atmosphere, in a physiologically effective degree, fade out, one after the other".

References are given at the end of each article. The book is well produced and has a good index.

K. E. Spells

# PROGRESS IN CYTOLOGY

## International Review of Cytology

Edited by G. H. Bourne and J. F. Danielli. Vol. 1. (Prepared under the auspices of the International Society for Cell Biology.) Pp. xii+368. (New York: Academic Press, Inc., 1952.) 7.80 dollars.

ANOTHER new biological journal, or more correctly a new biological annual, has appeared, and, when such an event occurs, perhaps the most natural question to ask in this age of overcrowded book-shelves is whether this new publication can justify its place. Does it provide information which is not available elsewhere or could not appear more appropriately in existing journals? If so, is the method of presentation as economical as it could be and as helpful?

The first volume certainly contains many interesting articles, and much new information is presented as well as some very useful syntheses. It has been the aim of the editors to make the review truly international, and while they have partially succeeded in this aim, with perhaps an inevitable Anglo-American slant, the policy is inclined to lead to difficulties in language and outlook (though the articles are all, in fact, written in English) unless the editors are prepared to edit more scrupulously than they have apparently done in presenting the subject-matter of the first volume. The purpose of the international review is presumably to allow cytologists in all branches of the subject to become familiar in a general way with events occurring in fields other than their own. Very few of us can be expert in all branches of the subject, and the jargon of each becomes more and more exclusive and unintelligible to the others. If, therefore, a review of cell biology is to be useful, it must be written in simple language which all can understand. It must be the primary object of each author of the review articles to explain his subject as simply as possible and not to be as cryptic and clever with his jargon as he can. Two examples will illustrate the dangers. The following paragraph presumably means something to the author and perhaps to workers in the same field, but one wonders how much it conveys to others: "The activators and inhibitors mentioned under the Tween techniques have no effect whatsoever on the hydrolysis of the naphthol esters, except that eserine ($10^{-4}$ M) appears to inhibit the activity of the muscle-spindles of the mouse considerably". Another pair of adjacent sentences in another article seems a little curious to the uninitiated: "This is the basis of the acid-Giemsa technique, which is now widely used for bacterial cytology. It is of course obviously derived from the Feulgen reaction, but produces much clearer preparations". Why is it of course so obvious? Perhaps in the second and subsequent volumes the editors will help the reader over such difficulties. They will have a hard task; but they will have to face it if the review is to succeed.

Some of the sixteen articles, which are on various topics ranging as a whole from bacterial nuclei through the localization and mode of action of enzymes to physicochemical studies of cell structure and even to a short historical note on early cytological research, are little more than original papers or summaries of original papers by the same author. While sometimes individually interesting, they are, in my opinion, out of place. On the other hand, such reviews as those on freezing and drying techniques, on the basis of staining processes and on enzyme action in the penetration of cell membranes, are on the whole well balanced and useful. Perhaps the most interesting theory which is developed—and it is the declared policy of the editors to provide space for the development of new theories—involves the folding and unfolding of protein molecules as a basis for osmotic work done by cells. This seems to be full of possibilities.

On a minor point, I would suggest that the lists of references should include the titles of the papers.

E. N. Willmer

# USEFUL PLANTS OF THE TROPICS

## The Useful and Ornamental Plants in Trinidad and Tobago

Revised fourth edition by R. O. Williams and R. O. Williams, Jr. Original edition by W. G. Freeman and R. O. Williams. Pp. 335. (Port of Spain: Department of Agriculture, 1951.) 2 dollars.

THE fourth edition of "The Useful and Ornamental Plants in Trinidad and Tobago", by R. O. Williams, sen. and jun., will doubtless prove, like the earlier editions of this extremely useful reference work, to be of value in many other tropical countries besides the West Indies, for a large proportion of the plants dealt with are, more or less, cosmopolitan throughout the tropics. The authors are father and son, and the work affords a good example of family enterprise and co-operation. Both are now engaged in agricultural work in East Africa, and the senior author has produced a somewhat similar work there ("Useful and Ornamental Plants of Zanzibar and Pemba").

At the present time there is increasing interest in economic plants of all kinds. This is particularly noticeable where food plants are concerned, and those plants that fall in the category of protective food plants or which are rich in vitamins. This is perhaps a natural consequence of a rapidly increasing world population and the demand for more and yet more food. Medicinal and drug plants are another group of economic plants that are attracting much attention. Many feel that the thousands of native medicinal plants throughout the world in use by primitive peoples are worthy of intensive investigation on modern scientific lines, and that more extensive use might be made of some of them. There is interest at the present time in those plants known to be used by various primitive races of the world, notably on the North American Continent, for inducing sterility, or temporary sterility, in mankind. At present practically nothing is known of the active principles of these plants or the manner in which they function. Some consider such plants might possibly be utilized, with proper control by the State, in curbing the too rapid increase in population that is now taking place in some countries, such as India. Paresta and fodder plants for the tropics and sub-tropics, particularly leguminous fodder plants, are another group to which special interest is attached. Books of reference on the economic plants of different parts of the world, outlining what is already known of the useful plants of the region concerned, are therefore very desirable at the present time.

In the new edition of the Williams's book the first part is devoted to lists of economic plants arranged in groups such as major and minor plantation crops, forest crops, the various food crops, cover and green-manure crops, fodder crops and grasses, medicinal plants, oil seeds, perfumes, etc. Other headings include fibres, hat- and basket-making materials, windbreaks and protective hedges, shade trees. The ornamental plants are dealt with similarly. In the main part of the book the species concerned are dealt with alphabetically according to genera. For each species the family and common name or names are indicated, and the space devoted to each is dependent upon its importance. Cross-indexing of common names has obviated the need for a separate index. The book is well arranged and easy to use. It is almost double the size of the original edition.

# AWKWARD PROPERTIES OF MATTER

**Deformation and Flow in Biological Systems**

Edited by Prof. A. Frey-Wyssling. Pp. xii+552. (Amsterdam: North-Holland Publishing Co., 1952.) 38 f.

A CRAFTSMAN knows by experience whether his materials are in the right condition for his work; and the technologist who sets out to replace this traditional skill by a mechanical process may well find himself at a loss for terms in which to describe, measure and specify the consistency of a clay, for example, or the stickiness of a glue. For the biologist the failure of his materials to conform to any classical pattern is often a source of serious difficulty when an attempt is made to interpret a biological function in physical terms.

The rheologist, in whose province these problems fall, may usefully attack them qualitatively by defining new criteria to replace others the meaning of which is obscured by everyday use: thus 'spinnbarkeit'—that property of a liquid which permits it to be drawn into coherent threads—has a specific meaning, while 'plasticity' is ambiguous. His quantitative problem consists in measuring the properties he has defined and relating them to more familiar physical concepts such as elasticity and viscosity; often modifying familiar equations by making their constants adjustable.

Both approaches are exemplified in this book—the first of a series on the rheology of natural and synthetic products. Containing as it does nine independent monographs, the book cannot set out a unified view of the rheological problems encountered in biology; but some topics such as the flow of a real liquid through a real tube do recur in a number of contexts.

A. Frey-Wyssling is concerned with the mechanism by which latex is extruded from elastic-walled storage tubes when these are opened by cutting into the bark of the rubber tree. He concludes that this is a passive process because its time-course is the same as that predicted theoretically for passive extrusion from an elastic tube. Other problems of flow in elastic tubes, including the physiologically important case of pulsatile flow, are dealt with by J. J. Hermans. Both contributions intentionally neglect departures from classical behaviour.

The importance of these departures is well brought out in the monograph by L. E. Bayliss on the rheology of blood. Thus the apparent viscosity of blood flowing through a tube is a function of the rate of shear, of the diameter of the tube (after allowing for the effect of tube diameter on rate of shear) and to a small extent on the duration of the shear. It is thus very difficult to compare viscosity measurements made by different techniques. Some of the anomalies are consequent upon the fact that blood is a suspension and that the spatial distribution of plasma and cells is modified during flow by the influence of velocity gradients.

R. D. Preston criticizes the theory that water may be drawn to the tops of tall trees in columns which retain their coherence even when the local pressure is far below the vapour pressure of water. The early measurements of the tensile strength of water gave high values which, he concludes, are not valid under conditions existing in the xylem elements. Moreover, if a cut is made into the cambium, dye solutions are sucked in with a time-course consistent with the theory that the xylem vessels are actually filled with air at reduced pressure.

That a qualitative or semi-quantitative approach to rheological problems may lead to valuable results is illustrated by G. W. Scott Blair's paper on the rheology of secretions. Characteristic changes in the consistency of cervical fluid occur during the œstrous and menstrual cycles, so that comparatively simple tests may be used to determine the time of ovulation. W. Seifriz's long monograph on the rheological properties of protoplasm also contains many qualitative observations of great interest, but his interpretation of them is often uncritical. For example, Kamiya's discovery that myxomycetes may exert flow pressure with a regular cyclic recurrence, and that this cycle can be analysed into Fourier components, should scarcely be attributed to "interplay of rhythm and harmony" in protoplasm.

The remaining papers deal with the plasticizer theory of muscular function; the relation between mechanical properties and structure in plant cell walls; the production and circulation of cerebrospinal and intra-ocular fluid; and with the diffusion of solutes, including gases, in tissues. The book ends with a short report of the first International Colloquium on Rheological Problems in Biology, held at Lund in 1950.

Most of the contributions are of a very high standard, but each will be of interest mainly to the specialist, who may not care to buy a whole book in order to obtain the monograph that interests him. However, the book undoubtedly deserves a place in every library that has a biophysical section.

D. R. WILKIE

## Gazetteer of Agricultural and Forestry Research Stations in the British Commonwealth 1952

Including a List of such Stations in the Republic of Ireland. Pp. xix+517. (Farnham Royal: Commonwealth Agricultural Bureaux, 1952.) 30s.

THE list of research workers in agriculture and forestry in the British Commonwealth, published in 1938 by the Imperial Agricultural Bureaux (as they were then), has long been a valuable reference book for all concerned. A post-war edition has been anxiously awaited and is to be greatly welcomed, particularly in the greatly extended gazetteer-form it has now taken. It will probably come as a surprise even to those engaged in work in these fields to find that particulars are included for more than a thousand research centres of various types situated within the Commonwealth.

Appraisal of the value of the changes in arrangement, and particularly in the indexes provided, will probably vary according to the special requirements and practice of the user. The gazetteer has dropped the alphabetical index of names of research workers with their countries in favour of an index to the actual research stations themselves. The former was useful in various ways and will probably be missed, while the names adopted by the research stations do not lend themselves to indexing without a lot of duplicate entries, difficult to select; the numerical device for ensuring quick recognition of the country in which the station is situated is helpful. The index for subjects of research is on a completely different basis from that of the 1938 list, and its compilation must have been a difficult and laborious task. It occupies about a hundred pages and gives references to the stations at which work is in progress on the subject in question, the serial number of the station again indicating its whereabouts; plant and animal indexes are incorporated. No attempt is made to indicate which are the major references; but this would obviously be almost impossible. Perfection is unattainable, but the outcome of a varied test on this index was quite good.

This gazetteer constitutes a much-needed and most important addition to existing facilities for intercourse and co-operation in research. H. G. C.

## Acoustical Designing in Architecture

By Prof. Vern O. Knudsen and Dr. Cyril M. Harris. Pp. x+457. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1950.) 60s. net.

JUDGING by the number of books on the acoustics of buildings that have appeared in recent years, it is evident that the science of acoustics is now assuming its rightful place among the physical sciences, and this advance is to be welcomed.

The authors of the book under review are well known in the world of acoustics, and they have produced a work which is comprehensive, satisfying and very readable. It is intended mainly for architects and students of architecture, and others who probably wish for a non-mathematical yet thorough treatment of the subject; but it is safe to say that many students of physics and engineering will also find the book worth reading and investigating.

The first part of the work is devoted to a discussion of the basic principles and general procedures of design that determine the acoustical properties of all types of buildings, while subsequent chapters show how these principles and procedures can be applied to obtain the best acoustical effects. Practical applications are emphasized, and examples of good design are worked out; in addition, comprehensive tables give pertinent data on sound-absorptive materials and sound-insulative structures.

The book is well written and produced, and it should certainly serve conveniently as a handbook in the solution of most architectural acoustical problems.

## Sound

By W. Hall and O. M. Matthews. Pp. viii+239. (London: Edward Arnold and Co., 1951.) 9s.

THE authors of this book have clearly recognized that a fuller treatment must now be accorded in schools to the subject of sound, a subject which is of ever-growing importance, and they have provided an excellent little book up to a point.

On the credit side, due emphasis is put on the importance of vibrations and waves, and the book certainly keeps abreast of modern developments, devoting one chapter to ultrasonics and another to technical applications of sound. But against these undoubted virtues, one feels that, although many facts are given and much ground covered, few topics are dealt with sufficiently fully for sixth-form pupils, and in my opinion a serious deficiency is the absence of detailed reference to the vibration of bars (of which the tuning fork is an outstanding example) and of membranes and plates.

Simple harmonic motion is dealt with in an appendix; but this might have been put in the text as a prelude to the discussion on wave motion.

If the book is intended for sixth-form use, it is suggested that some of the elementary work at the beginning might be omitted, and it is difficult to understand why, in such a small book on sound, two pages are devoted to the Doppler effect in light.

A good selection of questions of the appropriate standard is included at the end of each chapter.

T. M. Yarwood

## Proceedings of a Second Symposium on Large-Scale Digital Calculating Machinery

Jointly sponsored by the Navy Department, Bureau of Ordnance and Harvard University at the Computation Laboratory, 13–16 September 1949. (Annals of the Computation Laboratory of Harvard University, Vol. 26.) Pp. xxxviii+393. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1951.) 52s. net.

THIS conference included papers on complete machines, machine components in development, numerical analysis, programming, and surveys of the possible applications of high-speed computing machines in physics, aeronautics, applied mechanics, and economics. Although nearly three years have elapsed since the conference took place, there is still a good deal of interest to be found in the report; for example, in the descriptions of the Harvard Mark 3 machine and the Bell Telephone Laboratories Model 6 and—in the section on programming—in D. H. Lehmer's characteristically pungent remarks on pseudo-random numbers and the use of high-speed machines for calculations connected with number theory. The paper by Harry D. Huskey on semi-automatic instructions is well worth reading in view of present-day trends in the technique of programming. M. V. Wilkes

# MEASUREMENTS OF ICE THICKNESS IN DRONNING MAUD LAND, ANTARCTICA

By G. de Q. ROBIN
Department of Physics, University of Birmingham

THE Norwegian–British–Swedish Antarctic Expedition, 1949–52[1], which returned to Europe last February, carried out a comprehensive programme of glaciological, meteorological and geological research, making considerable use of geophysical methods. Particular attention had been directed to mountainous areas of Dronning Maud Land by the air photographs taken in 1939 by the German *Schwabenland* expedition. These indicated a particularly useful area for glaciological studies.

The expedition sailed from London in November 1949 in the Norwegian sealing vessel *Norsel*, and established its base, known as "Maudheim", in lat. 71° 03′ S., long. 10° 55′ W. on a floating ice shelf in February 1950. The weather experienced during the two-year stay was less windy than in some other Antarctic localities, which helped considerably in carrying out the programme.

In addition to standard meteorological observations, upper-air temperatures and winds were measured daily to heights averaging more than 10 km. Special studies were made of the radiation balance, and of wind and temperature gradients up to the 10-m. level. Glaciological work included measurements of net accumulation, surface movement and ice thickness both at the base and inland. A boring machine enabled temperatures to be recorded, and crystallographically undisturbed cores to be examined, from depths down to 100 m. at Maudheim, and corresponding work at shallow depths was carried out on journeys inland. Other work included a ground survey supported by air photographs, an extensive geological reconnaissance, and some physiological investigations.

The full scientific reports of the expedition will be published as a special series by the Norsk Polarinstitutt, Oslo. The following is a preliminary account and discussion of the measurements of ice thickness made by the expedition.

## Method

Thickness measurements were made by standard seismic reflexion shooting techniques, using equipment with six recording channels. The seismometers were normally spaced 10 metres apart in line with, and separated from, the shot point by distances of 10–200 metres according to the depth of the ice. The shots consisted of TNT charges of 90–720 gm. placed in hand-bored holes at depths of 2–12 metres.

Three distinct waves were produced by each explosion, the longitudinal (*P*) wave of around 3,800 m./sec., a second wave at about 1,650 m./sec. which may be a transverse (*S*) wave, and a Rayleigh wave at approximately 1,050 m./sec. Refraction shooting techniques were used to measure the velocity $V_P$ of the *P* wave at four different locations, with results listed in Table 1.

Table 1

| Date | Seismic station No. | Distance from Maudheim (km.) | Height above sea-level (m.) | Ice temperatures (°C.) | Velocity of *P* wave (m./sec.) |
|---|---|---|---|---|---|
| 18/10/51 | 38 (Maudheim) | 0 | 37 | −17 | 3,730 ± 20 |
| 30/12/51 | 165 | 185 | 480 | −19 | 3,775 ± 20 |
| 13/11/51 | 97 | 418 | 1,575 | −27 | 3,785 ± 20 |
| 25/11/51 | 119 | 615 | 2,710 | −40 | 3,810 ± 20 |

The change in velocity of the *P* wave with temperature is less than has been found by other observers[2,3]. As the normal refraction shooting technique results in measurement of the maximum value of $V_P$ rather than its mean value over a range of depths, the accuracy of soundings cannot be considered so reliable as the measurements of $V_P$ and echo-times would suggest. In view of the variation of $V_P$ with locality and of checks of seismic thickness measurements by independent methods[4,5], an accuracy of depth measurement of 5 per cent would seem a reasonable claim.

## Surface Profile

Distances were measured by meters on the tracked vehicles and by sledge meters. These distances were adjusted to fit astronomical observations made at important points.

Heights have been determined by aneroid barometers. Heights at control points were evaluated from surface pressure and pressure-height records from Maudheim. Between these points, heights are interpolated by barometer readings taken frequently when travelling between control points in rapidly moving vehicles. Errors should not exceed 30 m. for the first 300 km. from Maudheim, as they are means of three journeys. Beyond 300 km. the greatest difference of height measurements at the same spot on the outward and return journey was 60 m., and the error is not likely to exceed this amount.

The reported elevation of 4,200 m. for the surface of the ice sheet in Dronning Maud Land[6,7], the greatest claimed in Antarctica, was found to be incorrect. On a practically level ice sheet, within 2 km. of the charted position of one such report, our measurement showed an elevation of 2,670 m. This was in keeping with the results of the surveyor, N. Roer, which showed mountain heights to be substantially lower than previously reported.

## Seismic Shooting Results

Fig. 2 shows the route followed on the main seismic field-journey which took place during October 18, 1951–January 6, 1952. The lines of small additional profiles are also shown. Fig. 3 shows the picture of the ice and the underlying rock profile along the main route. For discussion, the profile may be split into the following five regions, all distances noted being taken from Fig. 3: (1) floating ice shelves from 0 to 35 km. and 55 km. to 142 km. which may also be termed ice barriers or shelf ice; (2) 'coastal ice hills'* from 35 km. to 55 km. and 142 km. to 176 km; (3) mountain ice sheet region from 176 km. to 470 km., less region 4; (4) mountain region from approximately 315 km. to 395 km.; (5) the inland plateau beyond 470 km.

## Floating Ice Shelves and 'Coastal Ice Hills'

Evidence that the ice shelf is floating will form the subject of a separate report. The most direct measure-

---

* This is a tentative name and the matter will be discussed shortly by the Royal Geographical Society's Committee on Antarctic Glacier Nomenclature. Other possible names are 'ice cupolas', 'ice swells' (which is more applicable to smaller features), 'ice shelf hills', etc.

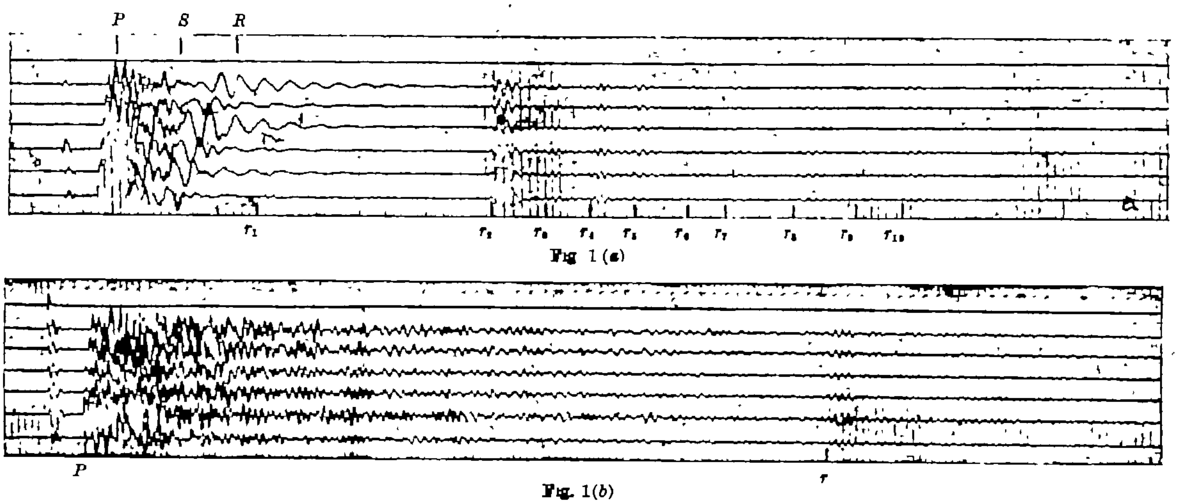

Fig 1(a)

Fig. 1(b)

Fig. 1. Seismic shooting records. The vertical lines represent time intervals of 1/100 sec. The top trace records the shot instant and the others the amplified output from six seismometers.

(a) Record taken on the ice shelf 2 km. south-west of Maudheim. *P*, longitudinal wave; *S*, transverse wave; *R*, Rayleigh wave; $r_1$, echo from bottom of ice shelf; $r_2$, echo from sea bottom, $r_3$, $r_4$, etc., echoes from lower surfaces and multiple echoes.

(b) Record taken on inland plateau 516 km. from Maudheim. Surface elevation, 2,505 m. Ice thickness ($r_1$), 2,290 m. On this record the output of adjacent seismometer channels are mixed to increase the apparent echo-strength, in order to overcome the excessive background noise caused by random snow collapse after the shot was fired

ment of the thickness of the floating ice at Maudheim has been made by the glaciologist, V. Schytt, by extrapolating his depth–density curve beyond its measured limit of 100 m., and using this together with the accurate surface elevation measured by N. Roer. This gives an ice thickness of 186 ± 5 m. Measurement of the *P*-wave echo-times from the bottom of the sea water for vertical and oblique rays through the ice shelf plus sea water gave a similar but less accurate result, 180 ± 30 m., for the ice thickness. This gives independent confirmation that the *P*-wave velocity is around 3,760 m./sec. for the whole thickness of the ice shelf, in contrast to the results found by Poulter[4] in the Bay of Whales area. He stated that the waves travelled with a velocity close to that in sea water when below sea-level in the ice shelf, thereby indicating that the sea water percolated through the ice shelf to that level. The glaciologists' core examinations and seismic shots fired at 100 m. depth (63 m. below sea-level) show that such an effect is not present at Maudheim. Wade's[5] figure of − 22° C. for the ice temperature at 41 m. depth (10 m. below sea-level) contradicts evidence of such percolation at the Bay of Whales.

At five stations, an echo has been observed which could not reasonably come from anywhere but the bottom of the floating ice. Schytt's thickness measurement at Maudheim has been used for calibrating this echo for other stations, as it is not clear whether this is a *P*-wave double echo (gives 205 ± 10 m.) or an *S*-wave echo (gives 215 ± 30 m.). In order to use the echo from the sea-bottom at stations where the ice thickness is unknown, the average of the five known values has been assumed as the ice thickness at that point. In view of the extremely flat nature of the ice shelf, this is unlikely to introduce errors of more than 50 m. in bottom depths.

Echoes obtained on the inland ice were verified to be *P*-wave echoes for a few stations, as is normally the case, and all inland ice echoes have been therefore taken as being such.

The profile across the hill 45 km. from Maudheim clearly shows the great increase in thickness where the ice is grounded. The profile does not cross the highest point of this 'ice hill'; but one seismic station was taken on the top of a smaller hill, and showed that the ice extends to 100 m. below sea-level there. The hill from 145 to 175 km. is similar in character,

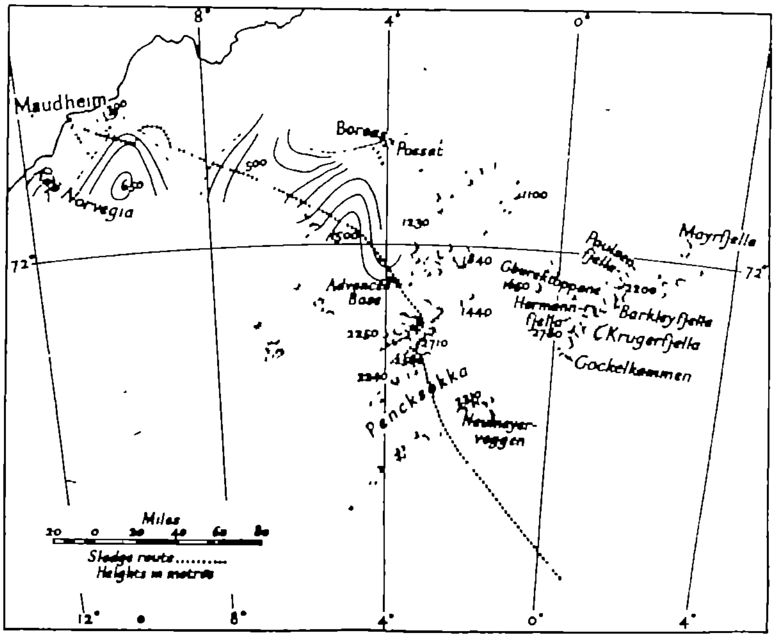

Fig. 2. Routes followed on main and subsidiary seismic journeys

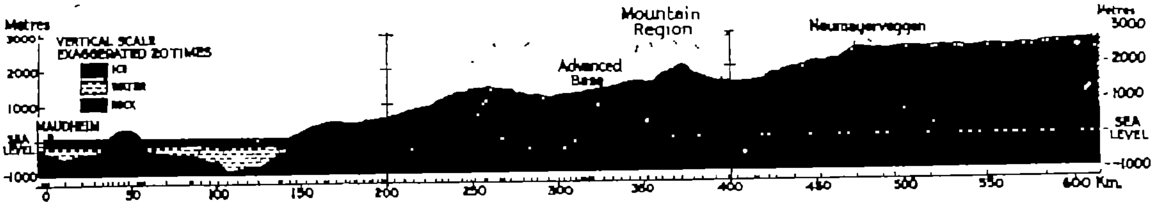

Fig. 3. Main seismic profile. The vertical marks above the distance scale show points at which seismic echoes were obtained

although it joins the mountain ice sheet on its inland side. The term 'coastal ice hill' is proposed for these features, where the visible hill is due to the accumulation of ice on a relatively flat base, and the form of which is determined principally by the mechanism of ice flow, rather than the underlying topography.

The detailed diagram (Fig. 4) of the ice shelf to inland ice junction is based on echoes at two seismic stations, plus theodolite levellings. A 1-m. change in surface level has been assumed to represent an 8-m. change in the thickness of floating ice.

As the mechanism of flow of ice shelves[10] has been neglected, compared with that of ice sheets and glaciers, the following points appear worthy of mention. (1) Although the upper layers of ice shelves may vary considerably in temperature at different localities, the bottom of an ice shelf is normally in contact with sea water, which is unlikely to differ much from − 1·8° C., its freezing point. (2) Except for layers nearer the surface, large density variations with locality appear to be unlikely. (3) As ice shelves are floating, they rest on a virtually frictionless base, and under some theories a theoretically negligible surface slope should be sufficient to cause flow. In these circumstances forces due to the rotation of the earth, and frictional forces with the air and sea should be considered, even though all these are small. (4) Fig. 4 shows clearly that, in a relatively short horizontal distance, the thick inland ice tends to thin out to a floating ice shelf of a thickness close to that at Maudheim and at other measured stations. (5) Accurate surface levelling at Maudheim by N. Roer showed that, in spite of the accumulation of more than one metre of firn, the general surface height above sea-level of the ice shelf changed by less than 5 cm. in twenty months.

In view of the above, and particularly of point (4), the idea that ice shelves tend to attain an 'equilibrium thickness' would appear reasonable, although probably an over-simplification. An ice shelf could then be formed by accumulation on frozen sea ice or coalescing glaciers without any appreciable flow taking place until such an equilibrium thickness was approached. When this had been attained, the additional accumulation would produce ice flow, by increasing the area of the ice shelf. In the absence of differential movement between different levels of the ice shelf, the following equation should hold:

$$\frac{\text{Annual net accumulation}}{\text{Equilibrium thickness of ice shelf}} = \frac{\text{increase in area per year}}{\text{total area}}$$

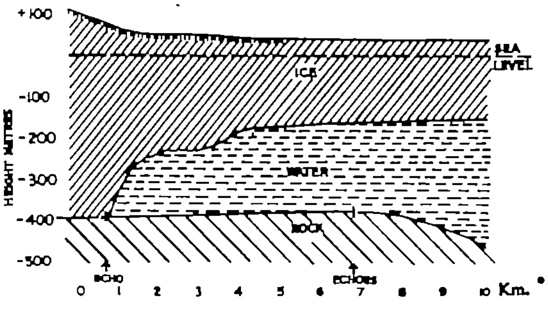

Fig. 4. Junction of ice shelf and inland ice 143 km. from Maudheim. Based on echo from ice–rock surface at 0·7 km. and from ice–water, and water–rock surfaces at 6·8 km., and from surface levelling by theodolite

Annual net accumulation in the above would also include any loss or gain on the bottom surface of the ice shelf due to melting or freezing of the sea water.

If we apply a possible figure of 40 cm. ice as the annual net accumulation over the Ross Ice Barrier, and take its equilibrium thickness as 200 m., as it is only free to expand to the north, we should get an advance of around 3 m. a day, compared with observed mean figures of up to 4 m. a day[9]. Accurate figures for this spreading which were obtained at Maudheim are at present being worked out by the glaciologists, Schytt and Swithinbank.

Now if an ice shelf is forming over an area of sea with insufficient depth to float this 'equilibrium' thickness, it will presently touch the bottom. If the area of contact remains small, any forward motion of the whole ice mass may slide the ice over the obstruction, as apparently happens in the Ross Ice Barrier. If the grounded area becomes too large, it will have to supply its own mechanism of flow by forming 'ice hills'.

Both the 'ice hills' shown in Fig. 2 follow the equations of flow $h = h_0/\alpha$ proposed by Nye[10], except near their edges, using the value of $h_0$ of $12\frac{1}{2}$ m., similar to that found in Greenland.

Such 'ice hills' are small-scale models of vast ice sheets, and as such may be worthy of thorough investigation. In Table 2, heights and minimum radii are listed for 'coastal ice hills'[11] with contours which suggest they are resting on a relatively level base. In each case the hills are wholly or partly surrounded by ice shelves. The calculated heights in the table are obtained by the formula proposed by Orowan[12] and later by Nye[10]:

$$h = \sqrt{2h_0 S},$$

where $h$ is the maximum thickness of ice; $h_0$ is a constant taken as 10 m., as Nye found in Greenland; and $S$ is the minimum radius of the hill.

The hill was assumed to rest on a level base 160 m. below sea-level, and a correction was applied assuming that shelf ice 200 m. thick surrounded the hills.

The increase of height with radius is clearly shown, and the agreement with calculated height is surprisingly good in four cases, considering the assumptions made about the underlying surface. The dependence of height on the area of the base was originally proposed so long ago as 1879 by Croll[13].

It is significant that values close to 10 m. for $h_0$ approximately fit hills listed in Table 2 and the depth

Table 2

| Position | Minimum radius $S$ (km.) | Observed height (metres above sea-level) | Calculated height (metres above sea-level) |
|---|---|---|---|
| 72° 15′ S. 60° 15′ W. | 5·3 | 190 | 220 |
| 71° 00′ S. 10° 07′ W. | 6·9 | 300 | 260 |
| 69° 55′ S. 61° 15′ W. | 7·2 | 300 | 270 |
| 70° 37′ S. 60° 48′ W. | 8·0 | 400 | 285 |
| 71° 00′ S. 60° 48′ W. | 8·8 | 490 | 305 |
| 71° 30′ S. 9° 50′ W. | 30 | 650 | 640 |

measurements on 'coastal ice hills' in Fig. 3. Nye found that the value of $h_0$ = 10 m. fitted the Greenland Ice Sheet, and values of 6–17 m. fitted European glaciers. Now $h_0$ is directly proportional to the shearing stress in the lowest levels of moving ice. Glen's laboratory studies on polycrystalline blocks of ice have shown that the shearing stress varies as approximately the fourth root of the rate of strain[14], so if other conditions are the same, the small spread in values of $h_0$ is not surprising. However, Glen has also found that the shearing stress required to produce a given rate of strain increases rapidly with decreasing temperatures, being approximately doubled when the ice temperature changes[15] from 0° C. to − 5° C. The inference is therefore that in the Antarctic the temperatures of the lowest levels of ice are not greatly below 0° C.

## Continental Shelf

From the evidence presented, it is apparent that the continental shelf of Antarctica may, if sufficiently shallow, be covered by gradually rising 'coastal ice hills', or, if deeper, its presence may still be hidden from ships by floating shelf ice. The reported absence of any antarctic continental shelf, as was reported[16] in longitude 3° E., cannot, therefore, be wholly based on ship-board information.

## Mountain Ice Sheet and Mountain Regions

Inland from 175 km. from Maudheim, the bottom relief changes remarkably to an alpine type, and so comes under Flint's[17] description of a mountain ice sheet, as a very occasional nunatak just breaks through the ice surface. On this section, several closely spaced stations were worked to examine the cause of step-like rises in the ice surface. At 187 km. such a step was apparently caused by a rock ridge submerged under 1,100 m. of ice at the point of measurement. At 210 km. and 248 km. the steps were caused by ice flowing over ridges some 500–600 m. below the ice surface, with the rock reaching its greatest elevation some 500 m. down slope from the crest of the step. Similar depths at 259 km. and 269 km. give the impression that, in this region, 500–600 m. of ice represents some kind of a critical depth for ice-flow across submerged ridges.

From 315 to 395 km. the route wound through a group of mountains rising to 2,700 m. above sea-level. This line of mountains runs towards the north-east with gradually decreasing height, and on either side of this line large glaciers drain the ice seawards. The valleys at 300 km. and 410 km. represent cross-sections of these glaciers. Ice-depths up to 2,000 m. in these valleys show that the underlying relief must be comparable to the most striking fjord type of country at present known, such as exists on the eastern coast of Greenland.

From 355 km. to 395 km. the ice depths were measured on mountain glaciers not more than 10 km. wide within the main mountain massifs.

From 415 km. to 475 km. the surface rises to the level of the exposed rock ridges of Neumayerveggen. The many crevassed patches on this escarpment make it probable that in many places peaks and ridges are not covered by any great thickness of ice. A typical profile would probably indicate a more jagged underlying relief than the gradual rise to Neumayerveggen which our measurements suggest. Our results here were influenced by the necessity of keeping our vehicles well clear of crevassed areas for reasons of safety, and also it was not possible to work anything like a desirable number of stations in the time available.

## The Inland Plateau

Inland from Neumayerveggen no rock is visible and the surface essentially becomes that of a high ice plateau formed by the damming of the ice on the inland side of mountain ridges. As there was considerable difficulty in obtaining soundings in this region, they are again too widely spaced to show much of the underlying relief; but the surface undulations seem to indicate that the rock floor is far from being a smooth basin. The soundings made at 615 km. show a bottom slope of 1 : 6 in direction 100° M. compared with a surface slope in the vicinity of the station of 1 : 440 in direction 200° M.

Unlike the central portion of the Greenland Ice Sheet, the rugged relief of the rock floor inland from 180 km. is such that the simple formula of Nye cannot generally be applied. While the underlying relief is in many ways reflected by the surface slopes in a more or less inverse proportion to the ice thickness, the direct interpretation of surface slopes is complicated by the damming action of ridges across the lines of flow. Further study here may, however, permit better interpolation of the underlying relief between seismic stations.

The findings described in this article have been the result of the work of the many people involved in the organization of the expedition, including the leader and other members of the wintering party at Maudheim, to whom I express my thanks. My particular thanks are due to my two companions throughout the seismic journey, P. Melleby (Norway), who looked after transport and camping equipment, and C. W. M. Swithinbank (Great Britain), who was responsible for navigation and general glaciology on this journey.

# COMPOUND HELICAL CONFIGURATIONS OF POLYPEPTIDE CHAINS: STRUCTURE OF PROTEINS OF THE α-KERATIN TYPE

By Prof. LINUS PAULING, For.Mem.R.S., and Prof. ROBERT B. COREY

Gates and Crellin Laboratories of Chemistry, California Institute of Technology, Pasadena 4

LAST year we described several configurations for polypeptide chains, and suggested that one of them, the α-helix, which has about 3·6 amino-acid residues per turn of the helix, is present not only in synthetic polypeptides but also in proteins of the α-keratin type, and in hæmoglobin and other globular proteins[1]. We pointed out that the dimensions of the unit of structure, as indicated by the X-ray photographs, and the distribution of intensities in the equatorial direction are roughly accounted for by the α-helix. In addition, we mentioned that the structure is supported also by the meridional reflexions observed for muscle fibres and porcupine quill, in particular the reflexions with spacings 1·5 A. (the length per residue along the axis of the α-helix) and multiples of this value; the value of this evidence was emphasized by Perutz[2], who observed the 1·5-A. reflexion for hair, horn, and other α-keratin proteins.

We also pointed out that the X-ray pattern of α-keratin, as described by Astbury and Street[3], has a strong equatorial reflexion at 27 A., which is not accounted for by a structure involving α-helixes in regular parallel orientation, and we suggested that this reflexion is due to a long-range order to be elucidated through further study. Other difficulties for the proposed simple structure of the α-keratin proteins have been emphasized to us by several workers in the field. The most important of these difficulties are a discrepancy between the observed and calculated density, and the failure of the α-helix to explain the 5·2-A. arc on the X-ray photographs as a true meridional reflexion.

We have recently noticed that an α-helix for a polypeptide chain involving repeating sequences of amino-acid residues of different kinds would be expected not to have a straight axis; instead, the axis of the helix would itself be predicted to pursue a helical course. A protein might consist of a single polypeptide chain with the configuration of a compound helix; three such helixes might well be expected to twist about one another, to form a three-strand rope, and six might be expected to twist about a seventh, to form a seven-strand cable; still more complex structures may also be formed. There is good reason for believing that hair, horn, quill, and other proteins of the α-keratin type consist of seven-strand protein cables in parallel orientation, with single compound α-helixes occupying interstices between them.

The study of simple substances related to proteins has not only provided reliable values of interatomic distances and bond-angles, but has also indicated that the N—H···O hydrogen-bond distance may be expected to vary by about ± 0·12 A. about its average value[4] in compounds of this sort, 2·80 A. Variation in the hydrogen-bond distance might be caused directly by the interaction of side-chains of amino-acid residues with the carbonyl and imino groups of the adjacent amide groups, or indirectly by steric hindrance (especially adjacent to a proline or hydroxyproline residue) or by attraction between side chains. Let us consider an α-helix composed of a polypeptide in which a unit of four amino-acid residues of different sorts is continually repeated. Two of the hydrogen bonds might be longer than the other two, by about 0·2 A. This difference in length would cause a curvature of the axis of the α-helix. If the α-helix has 3·6 residues per turn, the normal to the curved helical axis would be rotated by 0·09 revolution by progressing from one unit to the next unit of four residues along the chain, which corresponds to a complete revolution in about eleven units. The axis of the α-helix would itself accordingly describe a larger helix, with pitch approximately 66 A., the axial length of 44 residues. The radius of the larger helix would be about 1·5 A., and the sense of the larger helix would be the same as that of the α-helix. A compound helix of this sort is represented in Figs. 1 and 2.

Another simple case is that of the compound helix with a repeating unit of seven amino-acid residues. An α-helix with 3·60 residues per turn executes 97·2 per cent of two turns in seven residues, and would accordingly be expected to complete a turn of the larger helix in about thirty-five turns of the α-helix, or 126 residues, corresponding to about 190 A. for the pitch of the helix. However, the prediction of the pitch of this compound helix is rather uncertain; decrease by 1·5 per cent of the number of residues per turn would cause the predicted pitch to be doubled, to the value about 400 A. The radius

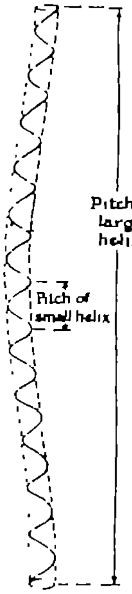

Fig 1

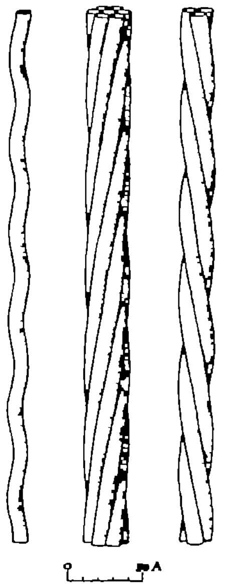

Fig. 2

Fig. 1. A compound helix with pitch of the large superimposed helix equal to 12·5 times the pitch of the small helix. For the compound α-helix the values might be 68 A. and 5·44 A., respectively

Fig. 2. At the left, a compound α-helix with pitch about 67 A. The diameter, shown as about 10 A., includes the volume occupied by side chains as well as the main chains of the protein. Centre, a seven-strand α-cable, with lead of about 400 A. In the proposed structures of proteins of the α-keratin type these cables are packed together, with compound helixes as shown at the left in the interstices. At the right, a three-strand rope, with lead of about 200 A., and with sense opposite to that of the seven-strand cable. In the suggested structure for feather rachis keratin, these ropes are packed together with seven-strand α-cables, in the ratio of two ropes to one α-cable

of the large helix might easily be as great as 10 A., with the variation in hydrogen-bond length mentioned above. The sense of the large helix of the seven-residue compound α-helix is opposite to that of the α-helix itself.

A radius of 6 A. for the large helix would permit three compound helixes to twist about one another, to form a three-strand rope (Fig. 2). Such a rope with the sense of twist of the strands opposite to that of the rope would be formed by the seven-residue compound helix, or with the sense of the strands the same as that of the rope by, for example, the fifteen-residue compound helix (with a repeating unit of fifteen residues, comprising nearly four turns of the α-helix).

Six compound helixes with radius of the large helix equal to 10 A. could twist about a central straight α-helix, to form a seven-strand cable. The repeating unit of seven amino-acid residues, comprising nearly two turns of the α-helix, is the simplest one that would give rise to compound helixes suitable to a seven-strand cable; the next simplest is the repeating unit of fourteen (perhaps containing one proline residue). A drawing of the seven-strand α-cable is shown in Fig. 2. We suggest that the symbol $AB_6$ be used for this cable.

The seven-strand α-cable is about 30 A. in diameter. A fibre containing these cables in parallel orientation would have a hexagonal unit of structure or pseudo-unit with $a$ equal approximately to 30 A. The observed equatorial reflexion with spacing 27 A. could then be explained as the 10·0 reflexion corresponding to this unit. The X-ray patterns of hair, horn, porcupine quill, and other α-keratin proteins are reasonably well accounted for by such a unit, with $a = 32{\cdot}4$ A. (for porcupine quill a multiple of this unit, indicating further superstructure, is needed to explain weak reflexions with larger spacing).

A plan of the packing of the seven-strand α-cable is shown in Fig. 3. It is seen that there is room enough at the positions ⅓ ⅔ and ⅔ ⅓ for other polypeptide chains to be introduced. If the adjacent seven-strand cables are staggered in azimuthal orientation, at a given level, α-helixes may be introduced in the positions ⅓ ⅔ and ⅔ ⅓. Because of the rotation of the cables, for which the value of the lead (vertical distance between a point on one strand and an equivalent point on the same strand after one turn about the cable) is about 400 A., and that of the pitch (vertical distance from one strand to an adjacent strand) is about 66 A., the inserted α-helixes must be compound helixes, with radius of the large helix about 1·5 A., and with pitch equal to the pitch of the cable, about 66 A. The sense of these compound helixes must be opposite to that of the cables, in order that they may fit between the strands of an adjacent cable. The four-residue compound helix, which has the proper sense and approximately the correct pitch, is accordingly satisfactory. We suggest the symbol $C$ for this compound helix.

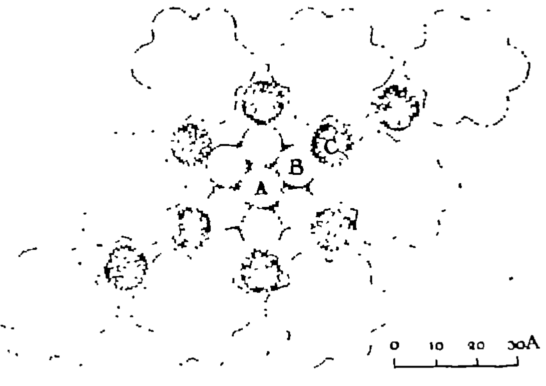

Fig. 3. A cross-section of the α-keratin structure, showing the α-cables $AB_6$ and the interstitial compound helixes $C$. The orientation of the cross-section of the cable changes with co-ordinate along the fibre axis. The central cable is shown in the most unfavourable orientation for the interstitial α-helixes. The protein chains are not so nearly circular in cross-section as indicated in the drawing, and space is filled more effectively than is indicated

The volume of a portion of the hexagonal unit with $a = 32{\cdot}4$ A., and with height 1·50 A., the axial length per residue, is 136·3 A.$^3$. The proposed structure involves nine amino-acid residues in this portion of the unit. With the reported range 107–118 for the average residue weight, the density of the protein is calculated to be 1·17–1·30 gm.cm.$^{-3}$. The indicated disagreement with the experimental value, about 1·32 gm.cm.$^{-3}$, may be due to the presence of a few per cent of water of hydration in the fibrous proteins. The much larger discrepancy between calculated and observed density that results from assuming the centre of the strong but broad equatorial reflexion, at 9·8 A., to correspond to the spacing of the reflexion 10·0 for the small hexagonal unit containing one α-helix is eliminated by the new indexing, which assigns the strong reflexion with centre at 9·8 A. to the overlapping of 21·0 at 10·6 A., and 33·0 at 9·3 A.

The strong 5·2-A. meridional arc, characteristic of the α-keratin proteins and previously given only rather unsatisfactory explanation in terms of the α-helix, is now explained in a straightforward manner as resulting from the co-operation of the seven residues, in a repeat involving approximately two turns of the α-helix, in the $B$ compound helixes of the $AB_6$ cable. With 1·50 A. as residue length of the α-helix, the unit of seven residues has length 10·5 A. The component of this distance in the direction of the fibre axis, assuming the cable to have lead 400 A. and radius 10 A., is calculated from the angle of inclination, 9·0°, to be 10·36 A. A weak meridional reflexion would be expected to occur with this spacing; the second order of this reflexion, with spacing 5·18 A., should be strong, because it involves reinforcement rather than extinction by the two turns of the α-helix in the repeating unit of seven residues. The 5·2-A. meridional arc, for which Astbury and MacArthur have recently reported spacings of about 5·15 A. or 5·18 A., is accordingly well explained by the proposed structure.

Strong support of the proposed structure is also given by many other features of the X-ray patterns of various proteins of the α-keratin type. One comparison of observed and calculated features is given in Fig. 4. At the top of this figure there is a sketch of the equatorial X-ray pattern of α-keratin. Astbury and Street[illegible] described the α-keratin pattern as having a strong reflexion at 27 A., a very strong and broad reflexion at about 9·8 A., and a vague region of darkening around 3·5 A. Examination of heavily exposed photographs shows that the last of these features is, in fact, a broad maximum, extending from about 5 A. to about 3·2 A. (This band may be due in part to the very strong 4·7-A. reflexion of β-keratin; it is known that specimens of α-keratin usually contain some β-keratin, and some of our photographs show a rather strong 4·7-A. ring.) There is then a minimum at about 2·8 A., a maximum at about 2·4 A., a minimum at about 1·8 A., a maximum

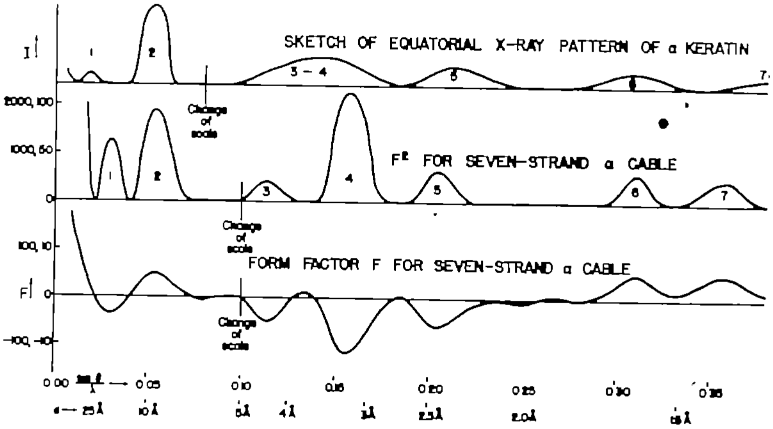

Fig. 4. Comparison of observed and calculated equatorial intensities on X-ray photographs of α-keratin. At the top there is a sketch of the observed intensity of reflexion by hair and horn. The decrease in intensity with increase in angle is more rapid than indicated. At the bottom, there is given the calculated form factor for the $AB_6$ cable, and in the centre the square of this form factor, which may be compared with the observed intensity curve

at about 1·6 A., a minimum at 1·4 A., and a further maximum. The form factor $F$ for the α-cable shown at the bottom of the figure is calculated by multiplying the form factor for the α-helix, including the β-carbon atom, as reported previously[1], by the factor $1 + 6J_0(4\pi\rho \sin\theta/\lambda)$, in which $J_0$ is the Bessel function of order 0, and ρ, the radius of the $B$ helixes of the cable, is placed equal to 10 A. Above the curve for $F$ there is shown the curve for $F^2$. It is seen that there is striking, although not complete, agreement between this curve and the sketch of the equatorial X-ray pattern. Inasmuch as the contribution of the two interstitial compound α-helixes and of the side chains, which together constitute just 50 per cent of the scattering matter in the fibres, have not been taken into consideration, the agreement must be considered to be excellent. It may be pointed out that, in the calculation of the form factor, no arbitrary parameters have been involved except the radius of the large helix; and that the value 10 A. for this quantity is required, to within a few per cent, by the dimensions of the unit of structure, if it is assumed that the three different kinds of polypeptide chains in the α-keratin proteins (the core of the cable, the six surrounding strands, and the interstitial compound helixes) have approximately the same average amino-acid residue weight.

The X-ray diffraction photographs of feather rachis keratin, which have previously been interpreted as involving β-keratin pleated sheets and α-keratin helixes in molecular distribution, may show a superimposed β-keratin pattern and α-keratin pattern. If this is correct, the α-keratin is different in nature from hair and horn α-keratin, probably consisting of $AB_6$ cables with $D_3$ ropes (three α-helixes coiled about one another) in the interstices. This structure accounts in a striking way for the characteristic features of the X-ray photographs.

The proposed structure of α-keratin involves three kinds of α-helixes, which presumably differ in amino-acid composition. We propose to examine these materials by fractionation. It is interesting that Goddard and Michaelis have reported that wool put into solution by reduction with thioglycollic acid or other reducing agent and treated with iodoacetic acid to form a carboxymethyl derivative can be converted into fractions with different chemical composition by ammonium sulphate precipitation[5]. We suggest that a solution of wool might be fractionated into the $AB_6$ cables and the protein keratin-C, and that the $AB_6$ cables might be further separated into keratin-A and keratin-B.

We think it not unlikely that actomyosin has the structure shown in Fig. 3, and that its fractionation into myosin and actin is a separation of the seven-strand cables $AB_6$ (myosin) from the single α-helixes $C$ (actin). The amounts of myosin and actin obtained by the fractionation are approximately in the predicted ratio 7 : 2, and, as predicted, the 5·2-A. meridional X-ray reflexion is observed for actomyosin and myosin but not for actin.

We are indebted to Prof. W. T. Astbury, Dr. I. MacArthur, Mr. F. H. C. Crick, and other workers in the field of the structure of proteins for having discussed with us the question of the structure of α-keratin, and especially for having emphasized the necessity for refinement of our suggestions. The detailed description of compound α-helixes and aggregates of them, and discussion of fibrous proteins which they compose, will be presented in later papers, to be published in the *Proceedings of the National Academy of Sciences* of the United States of America. This investigation was supported in part by a research grant from the National Institutes of Health, Public Health Service, and by a contract (Nonr-220(05)) with the Office of Naval Research. # THE RICCI CALCULUS

By Prof. H. S. RUSE
University of Leeds

GREGORIO RICCI-CURBASTRO, inventor of the tensor calculus, was born at Lugo, in Italy, on January 12, 1853.

The absolute differential calculus, as he himself called it, gained little attention until Einstein used it for the formulation of general relativity, even though it had reached a mature form by 1895, after some ten years of growth. It was so little thought of, indeed, that in 1901 Ricci was denied the Italian Royal Prize in mathematics on the ground that the calculus was "useful but not essential for the treatment of some mathematical questions". Nevertheless he himself retained a belief in its value, and in that had the sympathy and support of a young colleague at the University of Padua, Tullio Levi-Civita. The work captured the interest, too, of a young American, Luther Pfahler Eisenhart, who heard of it from Levi-Civitá during a visit to Padua in 1905, and from 1909 onwards used it in post-graduate courses on differential geometry at Princeton University. In 1912 Einstein's attention was directed to it by his colleague, Marcel Grossmann, and the outcome was the relativistic theory of gravitation published in 1916. Ricci was thereupon elected to a full fellowship of the National Academy of the Lincei, the last honour he received being his election to the Pontifical Academy in the year of his death, 1925.

For some fifteen years following 1916, the tensor calculus occupied a central place in mathematical research. Levi-Civitá's definition of infinitesimal parallelism in 1917 led to wide developments in differential geometry, these being coupled initially with the search for a satisfactory unified theory of gravitation and electromagnetism. At the same time the calculus was seen to apply to a number of classical physical theories, and notably to electromagnetism (as noted by Einstein and Grossmann in 1913), dynamics and elasticity. In recent years it has also been applied to network problems in electrical engineering; but this development has not gained universal acceptance among those interested.

To-day, in 1953, some knowledge of tensor analysis forms part of the ordinary intellectual equipment of most mathematicians and physicists. An account of it is usually included in university undergraduate courses, and numerous introductory books are available for those who want a working knowledge of it*. Most of these books contain chapters upon its physical applications, so the question may well be asked whether, for the physical sciences, the tensor calculus merely provides a convenient notation, or whether it is essential to them.

There is no need to dally over the word 'merely', since a good notation is a thing of value in itself. General tensor analysis (as apart from the theory of Cartesian tensors, which is little more than an alternative to ordinary vector and dyadic analysis) certainly provides the best means at present available for dealing with covariance and contravariance and with absolute differentiation, concepts implicit in traditional physical theories and explicit in relativity.

In ordinary three-dimensional vector analysis, no distinction is made between the covariant and contravariant components of a vector. The distinction arises, however, the moment one abandons a rectangular frame of reference in favour of an oblique frame, since a second oblique system, the axes of which are respectively perpendicular to the co-ordinate planes of the first, immediately claims attention. If units of length are suitably chosen, the two systems are said to be dual or reciprocal to one another, and the components of a given vector with respect to the two frames are respectively called contravariant and covariant. This generalizes to spaces of any number of dimensions and assumes a special importance in relation to curvilinear co-ordinate systems in flat or curved spaces, the mesh-system at each point providing a local frame of reference which is, in general, non-rectangular.

The concept of absolute differentiation likewise arises naturally and unavoidably. Like a mathematical M. Jourdain, one may in fact find oneself differentiating absolutely without knowing it. For example, the absolute time-derivative of the radial-and-angular-velocity vector $(\dot{r}, \dot{\theta})$ in plane kinematics is not $(\ddot{r}, \ddot{\theta})$, but is $(\ddot{r} - r\dot{\theta}^2, \ddot{\theta} + 2\dot{r}\dot{\theta}/r)$, the extra terms arising because the radial and transverse directions, which at each point provide a local frame of reference, change as one goes from the point $(r, \theta)$ to the point $(r + \delta r, \theta + \delta\theta)$. This example is a special one not only because it is concerned with a particular co-ordinate system in a particular space (a Euclidean plane), but also because the local frames are rectangular, the radial and transverse directions at any point being orthogonal. The intrinsic nature of absolute differentiation shows itself even more forcibly in connexion with general curvilinear co-ordinate systems, whether in Euclidean or in some more general space. The value of a calculus that deals simply and simultaneously with covariance, contravariance and absolute differentiation, in spaces of any number of dimensions, flat or curved, scarcely needs further demonstration. It is to be observed, too, that the relativistic principle of covariance, namely, that the general laws of physics can be expressed in a form which is independent of the co-ordinate system, has a meaning only in so far as there exists a way of expressing them in such a form. The Ricci calculus provides a means of doing so. Local frames are frequently used in relativity under the guise of local Galilean spaces of individual observers.

For a short time in 1928, the tensor calculus seemed, after all, inadequate for the expression of all general physical laws, since Dirac's relativistic equations for the electron did not obey the ordinary tensor laws of transformation. This led to the definition of a new kind of tensor, a spin-tensor or 'spinor', and to a significant development of the Ricci calculus, Dirac's equations thereby being brought into the covariant fold. Some time later it was shown that certain combinations of Dirac's equations, mathematically fully equivalent to the original set and expressible without the use of spinors, did, in fact, transform according to the ordinary tensor law. This result was of no physical significance; but it did show, once again, the adequacy of the ordinary tensor calculus for the framing of physical laws.

A distinctive feature of the tensor notation is the conciseness lent to it by its use of indices. A rather more elaborate system than Ricci's own has been developed by J. A. Schouten, its chief merit being a systematization both of notation and of terminology. A third style, originated by Élie Cartan, cuts the use of indices to a minimum, and, through his calculus of forms, often dispenses with them altogether. Cartan's notation has proved of greatest value in such purely mathematical theories as his own generalized geometries, the theory of groups and generalized potential theory (harmonic forms and harmonic integrals). The present tendency is in favour of the greatest possible simplicity of notation, and index-manipulation is certainly no longer regarded as a suitable full-time occupation for mathematicians. But the tensor calculus is fully established as one of the main instruments of modern mathematics, and gives to its inventor a permanent place in the history of the subject. The verdict of 1901 no longer stands.

---

* Books published since the end of the Second World War include Taylor, J. H., "Vector Analysis with Introduction to Tensor Analysis" (Prentice Hall, New York, 1947), Michal, A. D., "Matrix and Tensor Calculus with Applications to Mechanics, Elasticity and Aeronautics" (Chapman and Hall, 1947), Synge, J. L., and Schild, A., "Tensor Calculus" (University of Toronto Press, 1949); Lass, H., "Vector and Tensor Analysis" (McGraw-Hill, 1950), Sokolnikoff, I. S., "Tensor Analysis: Theory and Applications" (Wiley, New York, 1951), and Schouten, J. A., "Tensor Analysis for Physicists" (Oxford, 1951).

# OBITUARIES

## Sir Frederick Keeble, C.B.E., F.R.S.

FREDERICK WILLIAM KEEBLE, who died on October 19, was a biologist of great versatility who in his time was academic botanist, Civil servant, horticulturist with a flair for garden design, agricultural adviser to industry and, last but not least, a man who was a witty talker and one with marked literary gifts.

Keeble was born on March 2, 1870, and educated at Alleyn's School, Dulwich, and Caius College, Cambridge. After taking a degree in botany, he was appointed Frank Smart Student of the University of Cambridge, and spent a year in Ceylon on plant-physiological research. On his return to England, he became for two years assistant lecturer in botany at Owens College, Manchester. He was then appointed professor of botany at University College, Reading. where he stayed until, in 1914, he was made director of the Wisley Gardens of the Royal Horticultural Society. On the outbreak of war in the year of this appointment, Keeble was drawn away to war-work at the Board of Agriculture, where he became controller of horticulture in the Food Production Department. He did not, however, sever his connexion with Wisley until he became, in 1919, an assistant-secretary to the Board. While in this position, he did a great service to horticultural research, for it was with his support and encouragement that the constitution was drafted which, in 1919, gave East Malling Research Station its position as a separate independent institute.

He was soon, however, to resume academic work, for in 1920 he was appointed Sherardian professor of botany at Oxford. He held the chair for seven years; but after this there came a new phase in his career, for he was invited by Lord Melchett to become adviser in agriculture to Imperial Chemical Industries, Ltd. There his main concern was with the use of fertilizers, and under his direction the Company's experimental and research station at Jealott's Hill, near Bracknell, was developed. He resigned from his position with Imperial Chemical Industries in 1932.

The literary charm with which Keeble could invest a scientific subject was first brought home to his biological colleagues in a little book, published early in his career, entitled "Plant Animals", in which he described the behaviour of the curious animal, *Convoluta roscoffensis*, a heliotropic, chloroplast-bearing flat-worm inhabiting sandy tide-pools on the coast of Brittany. The same literary grace was also shown in the autobiographical "Polly and Freddie", which he published in 1936, and also in his articles in the *Gardeners' Chronicle*—a journal he edited during 1908–19. In addition to scientific memoirs, published mostly in the *Proceedings of the Royal Society*, he was the author of a number of other books—"Practical Plant Physiology", "Life of Plants" and "Fertilisers and Food Production".

Keeble was elected a Fellow of the Royal Society in 1913 and was knighted in 1922. He married in 1898 Matilde Maréchal, who died suddenly in 1915, leaving a daughter. In 1920 he married Lillah McCarthy, and while at Oxford they lived at Hamels, on Boars Hill. This was a place of great attraction, for the house was an old oak tithe-barn from Herefordshire adapted as a residence, and the garden, laid out by Keeble, one of great beauty.

Keeble had a quick mind and was a fluent speaker who could adorn his subject with wit and felicitous phrasing. Though on occasions he barbed his wit with sarcasm, he was essentially warm-hearted, as his friends knew well. For some modern scientific trends, such as mechanism, he had little sympathy. At a dinner held in his honour not long ago, he chose as the subject of his after-dinner speech the thesis, "The future of biology lies with the naturalist".

V. H. BLACKMAN

## Mr. J. A. Howe, O.B.E.

JOHN ALLEN HOWE was born on October 27, 1869, and died in his eighty-fourth year on December 11, leaving a widow and one son. He will be remembered by some of the older generation as the genial custodian of the old Museum of Practical Geology, 28 Jermyn Street, Piccadilly, London. This somewhat gloomy edifice, opened by the Prince Consort in 1851, was built not only to house the Geological Survey and its collections but also as a teaching and research establishment, particularly for natural history, chemistry, mining and metallurgy. Those classes ultimately grew into the Royal School of Mines and the Royal College of Science, which were later transferred to South Kensington, where they are now parts of Imperial College. They were followed there by their parent when the new Museum of Practical Geology in Exhibition Road was opened in 1935 to mark the centenary of the Geological Survey.

Howe, previously an assistant in the geological department of the Royal College of Science, joined the Geological Survey in April 1901. He served at first on the field-staff in Cheshire and in the London area, but in September 1902 was chosen to succeed Rudler as curator of the Museum. His early work was concerned with clays, roadstones and building stones, he maintained his interest in these materials almost to the last and was often consulted about them.

He was made assistant director of the Geological Survey, in charge of England and Wales, in October 1920, and continued in that post until his retirement in July 1931. The esteem in which he was held was marked by the award of the O.B.E. for his services to the Ministry of Munitions during the First World War, by the Bolitho Medal of the Royal Geological Society of Cornwall and by the presidency of the Institute of Mining and Metallurgy; he also served on the Council of the Geological Society of London.

Howe was a good companion, who will be missed, alas, by an ever-narrowing circle of friends and acquaintances.

T. EASTWOOD

## Mr. L. O. Newton

MR. L. O. NEWTON, who was honorary secretary of the Institution of Chemical Engineers for seven years, died on October 2 at the age of seventy. He was educated at Tiffins Boys School, Kingston-on-Thames, King's College (University of London) and the Sir John Cass Technical Institute. He served an apprenticeship with the Locomotive Co. of America and in 1902 became assistant works manager to the Locomotive Co. of Great Britain, Ltd. In 1907 he joined Lassen and Hjort, water purification engineers, and in 1912 became manager of Sofnol, Ltd., Greenwich, and from 1921 until his death was managing director. He was also retained as consulting chemical engineer to United Water Softeners, Ltd., London.

Mr. Newton had extensive experience in the manufacture of calcium hydrate, soda lime, etc. He practised as a consultant on industrial and domestic water supply and purification, trade wastes, air and flue gas purification and analysis.

Apart from his numerous scientific interests, Mr. Newton was also a member of Gray's Inn and brought to his position as honorary secretary of the Institution of Chemical Engineers invaluable help in all legal matters. He will be remembered by members of the Institution as a kindly and generous gentleman who did not stint himself in their service and who is sadly missed by all.

He is survived by his son, Mr. K. O. Newton; his widow, Mrs. V. Newton, only survived him by a few days.

WE regret to announce the following deaths:

Prof. Johan Bohm, director of the Research Institute for Organic Synthesis in Pardubice and associate member of the Czechoslovakian Academy of Sciences, on November 27, aged fifty-seven.

Mr. W. T. Gibson, O.B.E., chief valve engineer of Standard Telephones and Cables, Ltd., and manager of their Ilminster laboratories and factory, on December 27, aged fifty-three.

# NEWS and VIEWS

## New Year Honours List

THE list of New Year Honours conferred by H.M. the Queen contains the following names of scientific men and others associated with scientific work:

*Baron:* Lord Eustace Percy, rector of the Newcastle Division of the University of Durham during 1937–52;

*O.M.:* Prof. W. G. Penfield, professor of neurology and neuro-surgery, McGill University;

*G.B.E.:* Lord Brabazon of Tara, for services to civil aviation;

*K.B.E.:* Sir Patrick Laird, secretary, Department of Agriculture for Scotland;

***Knights:*** Dr. Harold Roxbee Cox, chief scientist, Ministry of Fuel and Power; Dr. Arthur W. M. Ellis, consulting physician, London Hospital, and emeritus professor of medicine, University of Oxford; Prof. William G. Holford, professor of town planning, University College, London; Prof. Harold Jeffreys, Plumian professor of astronomy and natural philosophy, University of Cambridge; Dr. Peter MacCallum, a member of the Medical Board, State of Victoria, and formerly dean of the Faculty of Medicine, University of Melbourne; Dr. James F. Mountford, vice-chancellor, University of Liverpool; Dr. Arthur Landsborough Thomson, second secretary, Medical Research Council;

*C.B.:* J. Buckingham, director of research programmes and planning, Royal Naval Scientific Service, Admiralty; Dr. W. H. Glanville, director of the Road Research Laboratory (Department of Scientific and Industrial Research); Dr. R. Spence, chief chemist, Atomic Energy Research Establishment, Harwell (Ministry of Supply);

*C.M.G.:* T. Hytten, vice-chancellor, University of Tasmania; R. C. Wakefield, director of surveys, Sudan Government;

*C.B.E.:* W. Cawood, deputy director, Royal Aircraft Establishment (Ministry of Supply); Prof. M. V. C. Jeffreys, professor of education, University of Birmingham; Dr. D. N. McArthur, director, Macaulay Institute for Soil Research, Aberdeen; Prof. A. Macbeath, professor of logic and metaphysics, Queen's University, Belfast; Prof. R. A. McCance, director of the Department of Experimental Medicine, Medical Research Council and University of Cambridge; J. Macdonald, director of research and education, Forestry Commission; G. S. Peren, principal of the Massey Agricultural College, New Zealand; H. J. Poole, chief superintendent, Armaments Research Establishment (Ministry of Supply); J. A. Smale, engineer-in-chief, Cable and Wireless, Ltd.; A. Turnbull, vice-chairman of the governors, Royal Technical College, Glasgow; C. J. Turner, chief engineer, Division of Atomic Energy (Production), Risley (Ministry of Supply); L. C. Tyte, deputy chief scientific officer, Fort Halstead (Ministry of Supply).

## Sir Hans Sloane, Bart. (1660–1753)

SIR HANS SLOANE, who died two hundred years ago, on January 11, 1753, is a striking example of a man upon whom the highest scientific honours were bestowed but who made no solid contributions to scientific knowledge. He was born at Killyleagh, County Down, Ireland, on April 16, 1660, and at the age of sixteen developed symptoms of pulmonary tuberculosis, so that for more than seventy-five years he had to lead a temperate life. He studied botany and medicine in London, Paris and Montpellier, obtained the M.D. of the University of Orange in 1683, and on his return to London lived with Thomas Sydenham, the 'English Hippocrates', who taught him practical medicine. At twenty-five he was elected to the Royal Society, and in 1687 a Fellow of the Royal College of Physicians. That same year he went to the West Indies as physician to the Duke of Albemarle, governor of Jamaica, but returned within eighteen months, after the duke's death, bringing back eight hundred different species of plants, of which he published a catalogue in Latin. He soon became a fashionable doctor in Bloomsbury Square, served as physician to three successive sovereigns—Queen Anne, George I and George II—and was the first medical practitioner to receive a hereditary title in 1716. He was president of the Royal College of Physicians during 1719–35. He introduced Peruvian bark into British medicine and popularized inoculation against smallpox. His association with the Royal Society was long and distinguished. In 1693 he was appointed secretary and revived the publication of the *Philosophical Transactions*, and in 1727 he succeeded Sir Isaac Newton as president, holding office for fourteen years. His best-known work, "A Voyage to the Islands of Madera, etc." (1707) was responsible for his election to the Paris Academy of Sciences. Sir Hans Sloane is remembered in history as a great collector, whose books, manuscripts and curiosities went to form the collection which was opened to the public in 1759 as the British Museum. In 1712 he purchased the manor of Chelsea, and to this day his memory is kept green by Sloane Square, Sloane Street and Hans Place. In 1721 he founded for the Society of Apothecaries the botanic garden at Chelsea. He retired from practice in 1741, and died twelve years later at the advanced age of ninety-three.

### American Association for the Advancement of Science: Prize Awards

THE Newcomb Cleveland Prize of the American Association has been awarded to Dr. Andrew M. Gleason, assistant professor, Department of Mathematics, Harvard University, for his paper on "Natural Co-ordinate Systems". This is the twenty-fifth award of this Prize, which is worth 1,000 dollars, and is made at the annual meeting of the Association for a paper presented as part of the meeting which represents an outstanding contribution to science.

A prize of 1,000 dollars for an essay on theoretical sociology, provided by a donor who wishes to remain anonymous, was offered by the American Association for the first time in 1951; none of the entries was considered adequate, and no award was made. The prize was offered again for 1952, for essays reporting upon inquiry into the theory of social processes and group behaviour, and has been awarded to Dr. Arnold M. Rose, Department of Sociology, University of Minnesota, for his paper on "The Theory of Social Organization and Disorganization". There were some sixty entries. Dr. Rose, who is thirty-two, was associate professor of sociology in Washington University, St. Louis, during 1947–49, and is now associate professor of sociology in the University of Minnesota; he held a Fulbright Fellowship in France during 1951. A series of papers submitted by Stuart C. Dodd, director of the Washington Public Opinion Laboratory, University of Washington, was given honourable mention.

### Oceanographical Exhibition in London

AN exhibition entitled "Exploring the Sea", which has been organized by the Royal Geographical Society and the National Institute of Oceanography, with the co-operation of the Hydrographic Department of the Admiralty, the Institute of Navigation and the British Museum (Natural History), was opened on January 3 at the Royal Geographical Society, Kensington Gore, London, S.W.7; the exhibition will remain open to the general public, admission free, until January 31 (10 a.m.–6 p.m., Sundays excepted). The object of the exhibition is to show how recent scientific developments have very much increased our knowledge of the underwater world, and the display has been arranged in three sections corresponding to work in the three principal fields of oceanographical exploration: "Exploring the Sea Bed", "Life in the Sea" and "The Moving Ocean". In the first section are included an instrument for recording sea temperatures photographically, a deep core, and the equipment for refraction shooting; a deep-sea echo sounder on show is arranged to measure variations of depth in a tank of water. In the section on life in the sea there are many specimens of plankton, a new plankton recorder, and different types of water bottles for taking samples and the temperature of water at depth. In the third section the effect of wind on waves is shown in a model; other exhibits include a working wave-recorder and instruments which record erosion and the graduation and profile of beaches, and current meters and tide recorders, which show how direct measurements of water movements are taken.

### Polymer Science: Seminar in University College, London

EIGHT lectures were given at a seminar on "Polymer Science", held in the Chemistry Department of University College, London, during October 24–December 5, 1952, and they can be classified under three headings: mechanism of formation of polymer, methods of establishing homogeneity, size and shape of polymer; and properties and reactions of macromolecules. In the first section, Dr. C. H. Bamford dealt with the general background of polymerization kinetics and with a study of some co-polymerizations from which it follows that the reactivity of a growing polymer is not solely determined by the terminal grouping. Factors were also discussed which influence the course of polymerizations under conditions such that polymer precipitation occurs. In the second section, Dr. R. A. Kekwick and Dr. P. Johnson reviewed theories and experimental details of the ultracentrifuge, electrophoresis and light-scattering measurements. Methods of determining the shape of macromolecules, particularly proteins, were indicated by Dr. A. Elliott and Dr. C. Robinson, who discussed results obtained with the help of polarized infra-red radiation and a new type of space-filling molecular models. The models are useful for demonstrating stiffness or flexibility of macromolecules. In the third section, on the properties and reactions of macromolecules, Dr. L. R. G. Treloar lectured on statistical thermodynamics of polymer – liquid interaction. Difficulties were pointed out which prevent the straightforward extension of the Flory–Huggins treatment to such systems as water and polar fibrous materials. Furthermore, the influence of external stress on equilibrium swelling was discussed. G. Stainsby, M. L. R. Harkness and Dr. A. Wassermann described the properties and reactions of ash-free gelatin and actomyosin. Prof. M. Stacey dealt with chemical and immunological properties of degraded dextran. Methods for breaking down these macromolecules and for fractionating the resultant products were also outlined. Each of the eight lectures was followed by a discussion, which was facilitated by making available, in advance, short abstracts indicating not only the main topic, but also the general background and important literature references.

### Application of Science in the Textile Industries

THE inaugural lecture "Science in Industry" which Sir Ben Lockspeiser delivered in the new premises of the Textile Institute, Manchester, on October 24, emphasized that the application of science to industry is the primary means of providing the power of adaptation to new conditions on which the economic survival of Great Britain depends. After illustrating this by reference to the part science has played in the introduction and application of the new man-made fibres and their effect on the older fibres, Sir Ben turned to the importance of the small firm in the effective application of science to industry. A recent survey in a small town engaged mainly in the light industries showed that only one-third of the firms had anyone with a special responsibility for advising on scientific and technical problems, and only half of these advisers had any technical qualifications. Sir Ben believed that a survey being conducted in the Manchester area would show that it is rare for textile firms employing five hundred people or less to employ a science or engineering graduate: only in the few firms with a thousand or more employees are scientific workers to be found in reasonable strength.

Sir Ben pointed out that the research associations in Britain are largely intended to help these smaller firms, and he went on to emphasize the wealth of opportunity in the exercise of craftsmanship to be found in this machine age if only it is recognized that the secret of craftsmanship lies in finer and finer control of the machine and in the apt choice of materials that goes with the knowledge of their properties. The extent to which exploitation is made of the vast field offered to the scientific worker and craftsman in fabrics manufactured from natural and mixed fabrics largely depends on the size and status of the textile industry. Success will depend on the knowledge of the materials being used, the appropriateness of machinery that is possessed for their utilization, and the instrumental aid which can be provided to enable the man at the machine to satisfy his creative instinct for craftsmanship. Such considerations, Sir Ben thought, are particularly important in industries that have grown from handcraft. He also suggested that the time spent on discovering the principles on which manufacture in the textile industry rests provides the surest basis for the solution of future problems, and creates the intellectual climate which promotes discovery and the growth of new ideas. It is in the utilization of results coming from the research associations that the Textile Institute is specially important, and on its members rests a large share of the responsibility for seeing that methods now available for the more economical use of materials and for quality control in mills and factories are used.

## Seed Health in Flax

Prof. A. E. Muskett, of the Faculty of Agriculture, Queen's University, Belfast, read a paper before Section K (Botany) of the British Association at its meeting in Belfast, in which he reviewed developments in the treatment of flax against seed-borne disease. A considerable number of such troubles include those caused by the fungi *Polyspora lini*, *Colletotrichum linicola*, *Botrytis cinerea*, *Fusarium lini* and *Phoma* sp. Seed-borne diseases of flax brought very considerable losses of yield during the First World War. The later discovery of organo-mercurial dusts did not solve the problem on flax as it did for cereals. 'Short-wet' methods were used, but eventually tetramethylthiuram disulphide ('Nomersan') was found to be the most effective seed-dressing. Prof. Muskett, however, went a stage further, and, using his 'Ulster' plating method, made a wide survey of the natural health of seed produced in various regions. This intensive work has now been continued for ten years, and shows that seed from the southern and eastern parts of Britain has little seed-borne disease. Larger yields of seed are, moreover, usually obtained in these drier and warmer areas. This simple but effective finding has been fully justified in practice, and the seed used in Northern Ireland is now all obtained from the south and east of England. The only disease fungus which is seed-borne to any extent from these areas is *Botrytis cinerea*, and that is dealt with by routine seed treatment. It is obviously much better to start with naturally clean seed than to treat diseased samples, and the results of this object lesson might well be applied to other crops and in other areas.

## Microbial Genetics at the University of Glasgow

The Nuffield Foundation has made a grant of £6,000 over three years for the expansion of research in the Department of Genetics, University of Glasgow. The grant will be used mainly for fellowships. It will make it possible to increase the research team working under Dr. G. Pontecorvo in microbial genetics. The approach followed in the past few years in the Department has been mainly that of making use of the resolving power of genetic analysis in order to get some insight into the details of biochemical organization of the cell. It is hoped that a strengthening of the team especially on the biophysical side may lead to useful advances.

## Canadian National Research Council Scholarships

The National Research Council of Canada intends to award about two hundred postgraduate scholarships which will be available without restriction of nationality for study in the fields of science and engineering during the year 1953–54. The majority of the awards will be tenable at Canadian universities and are divided into bursaries, studentships and fellowships worth, respectively, 600, 900 and 1,200 dollars each; they may be increased by an extra 500 dollars for the summer months. Bursaries are for graduates who have no previous research experience, studentships for those with at least one year of research, and fellowships for those in their last year of work for a Ph.D. About twenty of the awards will be tenable outside Canada and are divided into special scholarships for those who either have completed or are completing their work for a master's degree, and postdoctorate overseas fellowships for specialized training; the former are worth 1,500 dollars and the latter 2,500 dollars for twelve months. Applications should be made before February 1 to the Awards Officer, National Research Council, Ottawa 2.

## Announcements

The Institution of Mechanical Engineers has awarded its James Watt International Medal for 1953 to Sir Harry Ricardo, for his contributions to knowledge of the fundamental principles of internal combustion engines and the application of these principles to design and development. This Medal, which is in gold and is the highest honour that the Institution can bestow, is awarded every two years, and for it the Institution has the co-operation of the principal engineering institutions and societies in all parts of the world as nominating authorities.

The Council of the Royal Society has awarded two Mackinnon research studentships to the following: R. C. Jennison, of the University of Manchester, for work on radio astronomy at the Jodrell Bank Experimental Station; and Dr. F. K. Duxbury, of King's College, Newcastle upon Tyne (University of Durham), for work on organic chemistry at the University of Liverpool.

The American Association of Spectrographers is planning a symposium on "Emission Spectroscopic Determination of Metals in Non-Metallic Samples", to be held in Chicago on May 1. Papers in the fields of petroleum, geology, agriculture, pharmacy, biology, ceramics, etc., are invited. All inquiries should be directed to the chairman of the symposium committee, J. P. Pagliassotti, c/o Standard Oil Company (Indiana), Box 431, Whiting, Ind.

# SOIL FERTILITY AND CROP PRODUCTION

## MEETING IN DUBLIN

A JOINT meeting of Commissions 2 (Soil Chemistry) and 4 (Soil Fertility and Plant Nutrition) of the International Society of Soil Science was held in Dublin during July 21–31, 1952, under the auspices of the Irish Department of Agriculture, with Prof. F. Steenbjerg (Royal Veterinary and Agricultural College, Copenhagen) as chairman. The meeting was the outcome of a resolution passed at the Fourth International Congress of Soil Science, held in Amsterdam in 1950, when it was agreed that a need existed for a meeting to discuss as fully and critically as possible present techniques for the evaluation of soil fertility in relation to improved crop production. This was taken as the basis for the Joint Commission meeting, and some 148 soil scientists attended, representing universities, agricultural colleges, research institutes and government departments in many countries. The Vatican, the United Nations Food and Agriculture Organization, the Organization for European Economic Co-operation and the Mutual Security Agency sent observers.

Indoor sessions were held in University College, Dublin, during July 21–26, and were followed by a tour to places of agricultural and scientific interest in the south and west of Ireland during July 27–31. More than a hundred delegates joined in this tour. At the end of the meeting tributes were paid by various speakers to the Irish Department of Agriculture, for the success which attended the various sessions was in no small measure due to the fine work which the Department had done on the organization side of the meeting.

An introductory paper on the evaluation of soil fertility was read by Dr. E. M. Crowther (deputy director, Rothamsted Experimental Station). In his paper, which summarized many important aspects of the investigations on soil fertility, Dr. Crowther pointed out that the approach to soil fertility problems requires integration of several lines of investigation generally undertaken by separate groups of specialists. He listed these as the study of chemical, physical and microbiological characteristics of soil and of the physiology and biochemistry of plants; the characterization of soil and climatic conditions; the examination and improvement of farming systems; and the production and application of increasing quantities of better and cheaper fertilizers and liming materials. Dr. Crowther also stressed, as a priority need, the proper grading of laboratory tests for nutrients by proper field experiments.

The detailed work of the meeting was then divided between three sections. Section *A* dealt with laboratory techniques for assessing the nutrient status and nutrient-supplying potential of soils. This Section was divided into six different sessions. Section *B* dealt with plant and field techniques used in, and applicable to, the evaluation of soil fertility and was divided into two sessions. Section *C*, which dealt with correlation and general inquiry, was divided into three sessions. In all, eleven sessions were held. Each session was opened by a major review paper and two supporting papers dealing with important aspects of the subject-matter of the session. These papers were available in printed form in Vol. 1 of the Transactions of the meeting, and, consequently, it was possible to dispense to a very considerable extent with formal reading of papers and to devote the maximum amount of time to discussion. While in some instances discussion was along the lines of prepared papers, in the great majority of cases it was of a spontaneous nature. This procedure proved most successful, and the meeting was characterized by very lively and valuable debates. More than fifty additional papers and a summary of the discussions will be published shortly in Vol. 2 of the Transactions.

In Session 1, on organic matter and nitrogen, which was under the chairmanship of Prof. H. J. Page (lately principal of the Imperial College of Tropical Agriculture, Trinidad), the major review paper was given by Dr. H. H. Lees (University of Aberdeen), who paid particular attention to the importance of assessing the activity of carbon and nitrogen in soils in relation to fertility studies. In the supporting paper, Dr. G. Drouineau (Antibes Research Station) summarized researches on nitrogen in the south-east of France, and in another supporting paper Dr. J. Tinsley (University of Reading) reviewed the methods for estimating the organic matter status of soils. Many valuable contributions were made to the discussion, and it is obvious that there has been a considerable reawakening of interest in this sphere of study.

A considerable amount of work has been proceeding on methods aimed at assessing the phosphorus status of soils, but the fact that much still remains to be done in this field was made especially obvious during Session 2, which dealt with phosphates, and was presided over by Prof. J. A. Prescott (director of the Waite Agricultural Research Institute, Australia). The major review paper, on evaluating the phosphorus status of soils, was given by Dr. E. G. Williams (Macaulay Institute, Aberdeen), particular attention being paid during this paper to modern concepts of fixation processes. Dr. Williams stressed the need for an adequate programme of field experiments in evaluating the phosphorus status of soils. In a supporting paper Dr. L. A. Dean (Bureau of Plant Industry, Soils and Agricultural Engineering, United States Department of Agriculture, Beltsville) dealt with the use of radioactive phosphorus in evaluating soil fertility, and described in particular the usefulness of the 'A' value method as an index of the phosphorus fertility of soils. Other aspects of the use of phosphorus-32 in the study of soil phosphorus behaviour were dealt with by Dr. G. Barbier (Station Centrale d'Agronomie, Versailles), and a considerable amount of the discussion which followed centred around the use of this technique.

Session 3, with Prof. T. Wallace (director of the Long Ashton Research Station, Bristol) as chairman, was devoted to a consideration of various aspects of the potash status of soils. A review paper on the availability of native and fixed non-exchangeable soil potassium was read by Dr. R. F. Reitemeier (Bureau of Plant Industry, Soils and Agricultural Engineering, Beltsville), in which various extracting techniques were appraised and the role of non-exchangeable potassium discussed. The role of clay minerals in potash fixation was dealt with by Dr. S. Henin (director of research, Laboratoire des Sols, Versailles), and Dr. F. Alten (Hanover) discussed some fundamental aspects of the potassium nutrition of plants.

The recurring problems associated with the determination of lime requirements in the soil were fully discussed in Session 4, under the chairmanship of Dr. P. Bruin (acting director-in-chief, Agricultural Experimental Station and Institute for Soil Research, Groningen). This subject was introduced by Prof. S. Tovborg Jensen (Royal Veterinary and Agricultural College, Copenhagen), who examined important aspects, both practical and theoretical, of the determination of the lime requirement of soils, illustrating his remarks with the results of classical Danish experiments in this sphere. In a paper on a biological approach to soil acidity, Dr. E. J. Hewitt (Long Ashton) indicated the various factors associated with the soil acidity complex, and Dr. G. E. Smith (University of Missouri), in presenting a paper by Drs. Albrecht and Smith on soil acidity as calcium (fertility) deficiency, gave the basis of an approach which is gradually gaining considerable strength where the proper liming of soils is concerned. Though the work of this session indicated that a number of questions of outstanding practical importance still remain to be resolved in this sphere, it was clear that many of the seemingly conflicting ideas on lime requirement problems can easily be reconciled in terms of soil-type characteristics and plant requirements.

Session 5 (chairman, Dr. Henin) was a lengthy one and was devoted to consideration of methods for determining the magnesium and minor-element status of soils. The major review paper was read by Mr. W. Morley Davies (Ministry of Agriculture and Fisheries, Great Britain), and Dr. F. C. Gerretsen (Groningen) and Dr. E. B. Davies (Soil Research Station, Rukuhia, New Zealand) contributed supporting papers. These papers showed that much still remains to be done in the field of analysis of trace elements in soils, but considerable progress was reported by many of the delegates present. In this connexion the New Zealand approach, as outlined by Dr. Davies, where work on trace elements has been closely related to soil type, provides a very fine example of what the proper integration of research in this field can accomplish.

With Dr. R. K. Schofield (Rothamsted Experimental Station) presiding, Session 6, which was on the subjects of base exchange, nutrient balance and interactions, was notable for the attention which it focused on the importance of ion activity in evaluating soil fertility. This matter was fully discussed in the review paper by Dr. A. C. Schuffelen (Wageningen), and a paper on various aspects of the release and absorption of nutrients was presented by Prof. Wiklander (Royal Agricultural College, Uppsala). Prof. M. M. Elgabaly (Alexandria), in a supporting paper, discussed various aspects of nutrient element balance, pointing out the distinction which must be made between nutrient balance effects as determined in culture solution and soils. From discussions which followed, it was apparent that, with the development of new analytical techniques and a more thorough understanding of physico-chemical reactions, considerable advances in this field may be expected.

Session 7, presided over by Dr. Crowther, dealt with field experiments and pot culture techniques. Dr. F. Van der Paauw (Groningen), in a major review paper, outlined the methods in use for evaluating the nutrient status of soils by field experiments. This theme was further elaborated by Dr. H. L. Richardson (Central Agricultural Control, Imperial Chemical Industries, Ltd.), who illustrated his discussion by results from an elaborate series of field experiments directed by him in China. The resulting discussions were particularly valuable. Dr. J. W. S. Reith (Macaulay Institute) directed attention to the necessity for basing the evaluation of soil testing methods on further field experiments carried out on soils belonging to well-defined series. Pot culture techniques in evaluating soil fertility were dealt with by Prof. E. von Boguslawski (Germany), and a discussion on this subject attracted considerable attention.

In present-day work the diagnosis of soil fertility through plant diagnostic methods has come to play a very important part. This approach was fully discussed in Session 8 under the chairmanship of Prof. Steenbjerg. Prof. Wallace, who has been responsible for much of the work in this sphere, outlined in a major review paper the various methods used, and pointed out the necessity for a thorough understanding of soil characteristics for proper application of these methods. Dr. W. A. Roach (East Malling Research Station) discussed the various factors coming into play in the diagnosis of mineral deficiency by plant analysis and plant injection. The discussion which followed showed clearly the extent to which reliance is now being placed on this line of approach in many countries. In concluding this session, Prof. Steenbjerg directed attention to the importance of discriminating between extreme physiological disorders as determined in sand and water cultures and those mainly of a threshold nature which are observed under field conditions.

The extent to which soil test data can be used to evaluate soil fertility needs on a broad basis was discussed in Session 9, Prof. H. Kuron (Germany) being in the chair. The major review paper in this session was presented by Dr. W. L. Nelson (North Carolina State College), who dealt with soil test summaries and their usefulness to various workers engaged in the agricultural research and extension services. The supporting paper in this session was contributed by Dr. H. Riehm (Augustenberg, Germany), who discussed the value of the results of several million soil tests which had been carried out in Germany. Another aspect of survey work was discussed by Dr. L. de Leenheer (Ghent), who dealt with the determination of productivity ratings for different soil types. This is an aspect of the investigation of soil fertility which is attracting considerable attention and which must play an increasingly important part if soil survey is to be of increased value to agricultural technology.

Session 10 was devoted mainly to the consideration of methods used in soils advisory services in various European countries and presented the first systematic attempt to bring together an account of the techniques used. Dr. Nelson presided over this session, which was opened by a paper from Dr. K. A. Bondorff (Lyngby, Denmark) on the evaluation of soil analysis. Papers were presented describing the methods used in almost all European countries, and these, when finally published, should prove a valuable reference for workers in this field.

Session 11 was devoted to a discussion on general correlation, with Dr. P. H. Gallagher (University College, Dublin) as chairman. Dr. Bruin, in this session, outlined the development of soil fertility research in the Netherlands, being supported by a paper from Prof. Steenbjerg on general questions affecting the verification of chemical soil and plant analyses. These papers paid particular attention to yield curves and to various factors influencing the shape of such curves. The final supporting paper in this session was given by Prof. Prescott, who stressed the necessity for basing the solution of soil fertility problems on a full understanding of climatic and geochemical factors. In this connexion it would seem that the total analysis of soils may be considerably more important, especially where trace elements are concerned, than they are generally acknowledged to be.

The meeting was brought to a close in a session presided over by Prof. Steenbjerg, when certain proposals concerning international collaboration in the sphere of soil fertility were considered.

During the meeting a short tour took place in the adjoining counties of Kildare and Meath, where delegates inspected field experimental work, typical County Meath pasture land and peat bogs used for electricity generation. The tour, following on the indoor sessions, was designed to include experimental work relevant to the subject-matter of the discussions during the meeting, together with experimental work on liming problems, soil type characteristics in relation to phosphate and potash utilization, and trace element relationships, especially in connexion with livestock nutritional problems. During the tour an opportunity was provided of seeing some of the major soil series on which the agriculture of the country is based. A visit to an area in County Limerick where selenium toxicity is an important factor in livestock nutrition was of special interest. Visits to the Albert Agricultural College, Glasnevin, and Johnstown Castle Agricultural College were included; at the latter a day was spent examining the field experiments and the laboratories where routine soil testing is carried out on a considerable scale. An opportunity was also provided of seeing land reclamation and drainage units of the Department of Agriculture in operation.

T. Walsh

# THE BRITISH COUNCIL

## REPORT FOR THE YEAR 1951–52

The eighteenth report* of the British Council, covering the year ended March 31, 1952, again records a reduction in grants from United Kingdom funds, which for 1951–52 stood at £2,750,000, one-third being for work in the British Commonwealth, as compared with one-fifth four years ago. Of the Commonwealth expenditure, £365,000 came from the Commonwealth Relations Office and £523,000 related to the Colonies; of that sum, £80,000 from the Colonial Development and Welfare Fund was towards the welfare of overseas students in the United Kingdom. One section of the report gives a clear account of this important work among overseas students, of whom there are now more than five thousand from Colonial territories, as many more from India, Pakistan and Ceylon, and almost an equal number from other countries. For all such students the Council provides a programme designed to help them in their leisure time to meet people in Britain, to study the country's ways of life and modes of thought, and to help them to understand what has made and makes the British the people that they are. The London centre at 3, Hanover Street has a membership of more than eighteen hundred students representing a hundred and four countries, with an average daily attendance of two hundred and three hundred and fifty at the week-ends. The London hostels managed by the Council now accommodate two hundred and twenty men and thirty-five women out of more than two thousand five hundred Colonial students in London. Temporary residents at the Hans Crescent residence totalled nearly nine hundred in 1951, and permanent accommodation was found during the year for 1,071 overseas students, including 900 from the Colonies; for students outside London, the figures were 1,604 and 771, respectively. Accommodation in private lodgings was found for 538 overseas students in London and for 1,084 outside London. Some 2,600 students were met on arrival, and 5,504 attended Council centres.

The grants for work relating to foreign countries were reduced by 16·4 per cent to £1,862,000, and a further 9·0 per cent reduction in the estimates for 1952–53 brings the total reduction in five years to 42 per cent, the devaluation of sterling and rising prices abroad making the effective reduction in terms of work considerably higher. The Colonial Office Vote represents a reduction of 16·4 per cent since 1947–48, and the Commonwealth Relations Office Vote a reduction of 12·6 per cent on the peak year 1950–51. Together the reductions for 1951–53 have involved a diminution of 26 per cent in established posts, making 43 per cent since 1946–47. Expenditure in Latin America has been reduced by 41 per cent by closing the Council's own offices and reducing supply services. Except in Yugoslavia and in Germany, work in Europe has been substantially reduced, with the closure of all French provincial services and of the institutes at Turin, Venice, Valencia and Bilbao. The work in Egypt has been substantially reduced, and offices closed in Melbourne and Canberra as well as the institute at Aden, and three offices and centres in the United Kingdom have been similarly cut down. All supply services have been drastically reduced, notably expenditure on publications, lectures, books, periodicals and scholarships; about one-third of this expenditure is concerned with the sciences, including medicine and agriculture.

Work in the Middle East during the year has on the whole been encouraging. Although most of the twenty thousand volumes in the library in Cairo were lost by fire during the January riots, new premises for the British Institute and the Council's offices have been found, and reference is made to the part which the Council is playing in technical assistance throughout the Middle East, notably by bringing young men from the Middle East to the United Kingdom under its bursaries scheme or by giving assistance to the governments of those countries in placing their own nominees for training. Technical visits to Britain are also arranged for senior officers and specialists for short periods of study; and the Council's advice and help have been sought in recruiting British technicians to supervise training.

The present report includes a section dealing with the libraries of the Council, which now contain nearly nine hundred thousand volumes and are claimed to be the most far-flung network in the world. The Council's libraries in foreign countries are essentially special libraries, in which a high place is given to works on the English language and its teaching and to English literature of all periods, but which are also strong on subjects that fall into the framework of British civilization and institutions. In science, medicine and technology the tendency is to concentrate wholly on those aspects in which the British contribution has special significance for the country concerned. Expenditure on the purchase of books has fallen from £81,000 in 1947–48 to less than £20,000 in 1951–52, and of the latter sum only £1,500 was for books presented to other libraries (virtually all in the Colonial territories) compared with £19,000 in 1947–48, of which more than a half was for foreign countries. The scope of the Council's library activities in the Colonies has been restricted since 1948, but the report comments on the difficulty of keeping libraries supplied with new books on a budget a quarter of its size five years ago and with prices rising steeply: gaps left by years of scarcity are for the most part unfilled. Statistics for the stock, issues and membership of the Council's libraries are appended to the report. There are some remarkable variations in the ratio of book stock to monthly issues. Rio de Janeiro and Cairo, each with approximately 21,000 volumes, have monthly issues of 165 and 1,600, respectively. Ibadan and Zagreb issue 1,275 and 1,118 volumes monthly out of a stock of 3,000, while Barcelona issues 4,207 volumes monthly out of 10,000, Bandung (Indonesia) 2,124 out of a stock of 6,000, and Madras 1,709 out of 3,800. Only 44 out of Nairobi's 1,500 volumes, and 60 out of Blantyre's 1,200 volumes are issued monthly; there would seem to be room for some inquiry as to whether all the libraries are worth maintaining and whether the resources of others should be extended.

---

* Report on the Work of the British Council for the Year ended 31st March, 1952. Pp. 104. (London: British Council, 1952.)

# NEW ZEALAND DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

## REPORT FOR THE YEAR 1951–52

THE twenty-sixth annual report* of the Department of Scientific and Industrial Research, New Zealand, covers the year ended March 31, 1952, during which no expansion of activities was possible and those of many branches were curtailed in consequence of a restriction in the financial vote. Net expenditure for the year was £1,036,581, and, while the recruitment of scientific staff was exceptionally low, losses of experienced staff were high, although partly offset by the return from overseas of men who had completed advanced studies in various fields. The total staff on March 31, 1952, was 1,012, including 402 professional and 354 technical workers. Achievements of the year stressed in the secretary's report include the completion of geological surveys of the four main coalfields; very extensive coal-measures found in the Kaitangata field are of special interest. Surveys in North Auckland have indicated the rock formations associated with good and bad prospects for securing water supplies for farm purposes, while geological and geophysical investigations have located a hot area at Wairakei sufficiently promising for the inauguration of a development programme to prove the existence of a steam potential capable of generating 20,000 kW. Chemical investigations indicate that the steam has a low content of gas and is free from corrosive properties. An efficient geothermograph has been designed and constructed to measure temperatures at depth in bores.

Research on spontaneous combustion in wool cargoes indicates that the fires are confined to wools removed from skins by a bacterial process. These often contain a high percentage of body fat, and this potential source of danger can at present only be overcome by a very thorough scouring of the wool. The solution of this problem would save thousands of pounds annually. Following the discovery of the causal agents of the yellow-leaf disease of *Phormium*, it has now been found that the insect vector may be killed in all its stages by flooding areas growing New Zealand flax to a depth of two to three feet for fourteen days. Yellow-leaf disease has halved the production of flax fibre since 1938, and this advance promises to save almost the whole industry.

The nutritional value of the branched-chain acids discovered earlier in butter-fat is now being investigated, and accurate information on the changes in butter-fat composition that occur during the season has been obtained for the first time. A system for the certification of plant hormone sprays, based on the experimental work of the past few years, has now been established and is regarded as of considerable economic importance both in protecting growers from losses incurred in misapplication and in assisting manufacturers in production. Broad correlations revealed between soil types and tree-growth characteristics in soil surveys of the Kaingaroa Plains are expected to assist the State Forest Service in its development of the timber resources of this area as well as timber production, management and utilization elsewhere. The efficiency of boric acid in controlling *Ambeodontus*, the New Zealand wood-boring insect second in importance to *Anobium*, was proved during the year, and New Zealand timbers used for building and furniture can now be proofed against the three prevalent boring insects by treatment with boric acid.

In the tobacco industry use of methyl bromide as a soil sterilizer in seedling beds appears likely to supplant to a large extent the present costly and cumbersome steam sterilization operation. Striking results have been obtained in reducing the growth of laterals when tobacco plants have been topped by spraying the upper leaves with certain chemicals such as maleic hydrazide and mineral oil. Both discoveries promise considerable savings to the tobacco industry, while a new sample survey method of collecting agricultural and pastoral statistics designed by the Applied Mathematics Laboratory is expected to reduce markedly the costs incurred by the Census and Statistics Department in collecting this information. Investigations in the Dominion Physical Laboratory of a number of enclosed domestic stoves burning solid New Zealand fuels have shown that efficiencies of 45 to more than 70 per cent can be obtained, with proper design and control, compared with 10–15 per cent with the ordinary open-hearth fire. Since the cost installed does not exceed that of the ordinary chimney and grate, considerable savings should be possible in the use of coal for domestic heating. Radioactive cobalt and iridium have been used in the X-ray examination of welded metals and castings and in testing steel conduits for hydro-electrical installations. Further work by the Leather and Shoe Research Association on the modification of New Zealand fish liver oils for the production of chamois leather has yielded a process for utilizing vegetable oils in oil-tanning which, besides producing stronger leather, enables white washable gloving leather to be obtained without bleaching. Bark from *Pinus radiata* has been proved to be a possible source of tannin, and the detrimental effect of high temperatures upon pickled pelts in storage and transport has been demonstrated. The investigations by the Pottery and Ceramics Research Association indicate that for ceramic manufacture deposits of ball clays from Canterbury, Otago and Southland are equal in quality to any such deposits found elsewhere in the world.

# OCEANOGRAPHY IN THE UNITED STATES

IN 1927 the United States National Academy of Sciences appointed a Committee to consider the share of the United States in a world-wide programme of oceanographical research. Much of the Committee's report was published in book form under the title "Oceanography: Its Scope, Problems and Economic Importance", by Henry B. Bigelow (1931). One of the major outcomes of the decisions of that Committee was the building and endowment of the Oceanographic Institution at Woods Hole, and there was a general all-round increase in marine research.

In 1949 a second Committee on Oceanography was established by the National Academy. The reason for the setting up of this second body was not lack of interest in oceanography. Owing to the recognition of the practical applications of oceanography during the Second World War, marine research had, in fact, flourished; but it was chiefly government sponsored. As a result of inflation and the heavy cost of maintenance of modern research ships and equipment, private endowments were entirely inadequate, and research could only continue at its present scale with heavy government support. The Committee considered that "the healthy growth of oceanography has been hampered by the uncertainty as to how long this support may be available, and by other restrictions". It was to report on this situation that the Committee was appointed. Its report, entitled "Oceanography 1951", is now published*.

As in the previous report, the relations of the science to biology, geology and meteorology, and certain recent notable advances, are surveyed. The advance in physical oceanography has been very striking. That this is so is largely due to the War, which has resulted in the provision of "a nucleus of 80 to 100 physical oceanographers in this country, compared with perhaps half a dozen prior to 1930. . . . More than half of the funds being expended for oceanographic investigations at the present time come from the Department of Defence".

The sea is a source of food, and it is necessary to ensure that research is also directed towards increasing the yield from the sea fisheries, as well as gaining knowledge useful in war. The annual yield of the world's fisheries is quoted as twenty million tons, giving only one-fiftieth of the total protein consumption, yet half the world's population has a diet seriously deficient in protein. The Committee considers that "Heretofore most fishery research programmes were attempted on too small a scale. This was due to lack of appreciation of the complexity and magnitude of fishery problems, so that insufficient funds were assigned to many projects". Recently, however, there have been large-scale attacks on certain problems, such as the causes of the disappearance of the Californian sardine; the potentialities of the pelagic fisheries of the central North Pacific; and the movements of the Gulf Stream.

But the Committee considers that oceanography is not developing in a well-balanced manner and that there is almost no financial support for general marine biology. It thinks that inadequate attention is being paid to many challenging problems which do not have military significance and do not bear on specific fisheries; and it feels that, in order to ensure more freedom of research into such basic problems, greater private financial support is needed. At the same time, government support on a liberal and far-sighted basis should be continued, to provide the large-scale co-ordinated effort which the size and complexity of oceanic phenomena demand. Through the United Nations and President Truman's Point Four Programme, the United States should also encourage the development of oceanography in other countries, and especially in the southern hemisphere and western Pacific. The Committee recommends the securing of private funds for the provision of research fellowships at existing oceanographic institutions; for facilities for visiting investigators; for the provision of more permanent posts; and to supply increased funds for operating ships and for basic research in biology and chemistry.

The present total income of institutions in the United States carrying out oceanographical research is about 2,300,000 dollars, four-fifths of which is supplied by the government. It is recommended that the additional funds from private sources should be between 500,000 and 750,000 dollars. This would bring the total annual expenditure on oceanographical research into the region of one million pounds sterling by those laboratories other than the Federal and State organizations.

# PRESERVATION OF THE LAKE DISTRICT

THE Report and News Letter for August of the Friends of the Lake District* records a discouraging year, and refers particularly to the absence of a Joint Planning Board except in name for the Lake District National Park and to the hobbling of that authority by the failure to appoint a planning officer for the Park. The practical consequences of this position are concisely and clearly indicated, as well as the requirements for the effective functioning of any joint board. Local matters on which the Report and News Letter comment are the assurance received from the superintendent of the Eskmeals military range that the proposed night firing is, in fact, abnormal, and the decision given by the Minister of Fuel and Power in favour of the Electricity Board's proposal to serve farms in Martindale by overhead lines.

---

* Friends of the Lake District. Report and News Letter, August. Pp. 20. (14 Princes Street, Ulverston, 1952.)

In Langdale no change is reported in the Electricity Board's policy of withdrawing the scheme on grounds of economy; but reference is again made to the improvement of the Hardknott from a mountain trackway with a loose rough surface into a motoring road in spite of the clear and unequivocal assurance to the contrary given in November 1946 by the chairman of the Highways Committee of the Cumberland County Council. Attention is also again directed to the general difficulty that arises because the virtual control of road-widths and traffic policy is in the hands not of the new Planning Board or even the local highway authorities, but of the Licensing Authority, a body which is detached from any interest in the preservation of the countryside. The intricate work of completing the footpath survey and official statutory map is likely to continue for another two years at least, but the review of open country in the area has been completed in the counties of Cumberland and Westmorland and in the National Park as a whole.

The Friends of the Lake District have been concerned in a preliminary review of the needs and possibilities of new footpaths on the shore of Lake Windermere, and representations have been made regarding the minimum flow in the Dash Beck water scheme for the rural district of Wigton as well as the construction of any necessary buildings. Together with the Council for the Preservation of Rural England, the Friends of the Lake District have made representations regarding the Forestry Commission's proposal to plant Low Holme Park exclusively with conifers and its effect on the footpath between Eskdale and Nether Wasdale.

# NEUROSECRETORY PATHWAYS IN THE HEAD OF CRUSTACEANS, INSECTS AND VERTEBRATES

By PROF. BERTIL HANSTRÖM
Zoological Institute, University of Lund

STUTINSKY[1,2] and B. Scharrer[3,4] have recently proved that the chrome-hæmatoxylin-phloxin of Gomori selectively stains the neurosecretory pathways in several of the Pterygota in identically the same way as it stains the neurosecretory tractus supraoptico-hypophyseus in vertebrates (Bargmann[5], Hanström[6]). Thus, to the formerly known detailed similarities between the corpus cardiacum – allatum system in insects and the hypophysis in vertebrates—similarities which were originally pointed out by me in 1941 [7]—the fact has been added that the neurosecretory tracts, which in insects connect the pars intercerebralis of the brain with the corpus cardiacum and in vertebrates the nucleus supraopticus (and the nucleus paraventricularis) of the diencephalon with the neurohypophysis, both react positively and selectively with the Gomori stain. I think it worth while also to consider whether the neurosecretory substance in insects—as seems to be the case in vertebrates (Bargmann and E. Scharrer[8])—is connected with the production of a hormone regulating water-balance.

In 1940 [9] I described in some of the Apterygota two groups of cells on the surface of the protocerebrum which lie within a separate connective tissue sheath, only connected with the brain through a small aperture in their capsule. On account of their position, these groups of cells ought to be the homologue of the lateral frontal organs in crustaceans and the X-organs of these arthropods, which in 1934 were described by me as neurosecretory structures and which are transformed frontal organs. In the Apterygota these groups of cells give rise to a pair of nerves which take a characteristic course through the brain and can be traced outside it into the corpora cardiaca. In addition, I found that the cells in *Petrobius maritimus* contained secretory droplets which could be traced for a considerable distance along the axons. In higher insects these groups of cells ("the medial neurosecretory cells"), which give rise to the same nerve, are situated within the ordinary brain capsule, but otherwise show the same relations. Thus the lateral frontal organs, which in several lower crustaceans are located in the hypodermis and completely independent of the brain (though connected to it by a nerve), in other crustaceans are transformed into the X-organs, which adhere to the brain, and in the Apterygota into the groups of neurosecretory cells on the surface of the protocerebrum. In the Pterygota, finally, they have been thoroughly retraced into the brain as the medial neurosecretory cells of the pars intercerebralis, which cells, according to E. Thomsen[10] (cf. M. Thomsen[11]), must be regarded as the over-all controlling centre of the endocrine system in insects.

For comparative neurological reasons, I first assumed that a synapse may be present in the nervous pathway between the groups of neurosecretory cells and the corpora cardiaca in the Apterygota, though I did not try to verify this assumption by using special nerve-staining methods. Owing to the considerable physiological importance of the medial neurosecretory cells, which has been proved by a number of recent investigators for the Pterygota, I have now applied the chrome–hæmatoxylin–phloxin method of Gomori to several series of sections through the head of *Lepisma saccharina* and one series of *Petrobius maritimus* with the following result, which mainly deals with the former species.

Within the whole brain, nothing but the medial neurosecretory cell groups, their axons, and their endings within the corpora cardiaca have stained deep blue or blue-black with the hæmatoxylin. The plasm of the cells themselves contains conspicuous small droplets or irregularly formed larger colloid masses of the secretory product, and small droplets are also found along the greater part of the axons. The axons are very delicate, and since the number of neurosecretory cells is very small, the axons cannot be clearly observed without an oil-immersion lens. With the aid of an oil-immersion objective, however, the thin bundle of axons could be seen standing out very sharply, stained blue-black against the phloxin-red of ordinary nervous tissue from the entry of the nerves at the surface of the brain all the way into the corpora cardiaca. Thus, there were no signs of any synapse in the neurosecretory pathway, either in *Lepisma* or in *Petrobius*; further, no such structure has been mentioned in the Pterygota by Stutinsky[2] or by B. Scharrer[3]. At the entrance of the secretory fibres into the corpora cardiaca of *Lepisma*, they become thicker and are equipped with smaller or larger—often relatively considerable—enlargements, which stain as blue-black as the axons and droplets within the cell bodies. The special cells of the corpora cardiaca, on the contrary, do not show any hæmatoxylin reaction at all. This seems to be another parallel to the relations in the hypophysis, in which only the neurosecretory nerve endings from the hypothalamus in the neural lobe and no other colloid in this or the glandular lobe is truly Gomori-positive (Hanström[9]).

In this connexion it is interesting to note that Passano[12] and Bliss[13] seem to have detected at last a function for the X-organ in crustaceans. According to these authors, it is actually the cells of the X-organ which secrete the moult-inhibiting hormone and transport it through their axons into the sinus gland, described by me in 1931, in which structure it is accumulated, and then released into circulation in the adjoining blood sinus. As regards the nature of the secretory mechanism, the X-organ plus the sinus gland can thus be compared with the hypothalamo–hypophyseal system in vertebrates, and the pars intercerebralis–corpus cardiacum system in insects. This latter interpretation further supports the parallels between the X-organ and the medial neurosecretory cells. In addition to the common origin from the lateral frontal organs, there is a similar neurosecretory function: the secretory product is not directly released into the circulation but is transported to a place of storage, the sinus gland in crustaceans and the corpus cardiacum in insects.

It should, however, be pointed out that the parallel between the X-organ – sinus gland system in crustaceans, the pars intercerebralis – corpus cardiacum – allatum system in insects and the complete hypothalamo – hypophyseal system in vertebrates is less perfect than the mutual comparison between the latter two systems, as shown by me and by the Scharrers in earlier papers. Thus, in crustaceans, only the first two links of the chain are present, the X-organ and the sinus gland (comparable, respectively, to the medial neurosecretory cells and the corpus cardiacum in insects, and the neurosecretory nuclei of the hypothalamus and the neural lobe of the hypophysis in vertebrates), while the third link is missing, being represented by the corpus allatum and the glandular lobe (adenohypophysis), respectively, in the other two animal groups. Exceedingly interesting and suggesting a similar structure is the light blue colour which distinguishes not only the neurosecretory cells of the pars intercerebralis of the insect brain, the cells of the X-organ (and the sinus gland) in crustaceans, and, at least in some instances, the neurosecretory cells of the hypothalamus in vertebrates.

Though the medial neurosecretory cells in the Apterygota are placed on the surface of, not within, the brain, they show the same specific staining reaction and the same relations to the corpora cardiaca as in the Pterygota. In accordance with B. Scharrer[3], I conclude that the neurosecretory substance is produced by these groups of cells and transported along their axons into the corpora cardiaca, from which it can easily be released into the circulation because these glands adhere to the aorta.

It may finally be added that an investigation of the function of the endocrine system of the head of apterygotous insects, such as *Lepisma* and *Petrobius*, might yield interesting results. The position of the medial neurosecretory cells outside the brain should facilitate extirpation and transplantation experiments, and the particularly simple structure of the incretory system (in which the corpora allata are missing; Hanström[9], Cazal[14]) and the simpler development of these primitive insects, examined in relation to hormonal factors, may be able to throw new light on the regulation of the more complicated development of their higher relatives.

# THE LIGAMENT IN THE LAMELLIBRANCHIA

By G. OWEN, E. R. TRUEMAN and
PROF. C. M. YONGE, F.R.S.

Departments of Zoology, University of Glasgow and
University College, Hull

THE ligament in the Lamellibranchia should be considered in relation to the different layers of the shell, of which it is an integral part, and so in terms of the areas responsible for the secretion of these layers. As is well known, the shell consists of a superficial periostracum and underlying outer and inner calcareous layers. These three layers have different origins. The periostracum is secreted as a thin sheet within a groove between the outer and middle lobes of the mantle edge, while the outer calcareous layers are produced by the outer lobe of the mantle margin and the inner calcareous layers by the general surface of the mantle. Thus growth of the periostracum and of the outer calcareous layers is by increment from the periphery of the mantle, while the inner calcareous layers normally continue to increase in thickness throughout life.

The Lamellibranchia were probably derived from ancestors having a simple dome-like shell with a single centre of calcification[1]. In the course of evolution the mantle became greatly extended and laterally compressed. This must have been accompanied by the partial division of the mantle into lateral lobes each possessing a centre of calcification. These two pallial lobes remained connected mid-dorsally by a neck of tissue, the shell in this area being left largely uncalcified[2] and constituting the ligament. Thus the shell in the Lamellibranchia consists of two valves with a dorsal connecting ligament.

It is proposed to describe the connecting neck of tissue between the two lobes of the mantle mid-dorsally as the 'mantle isthmus'. This represents the original mid-dorsal surface of the mantle. This region has frequently been described as the pallial

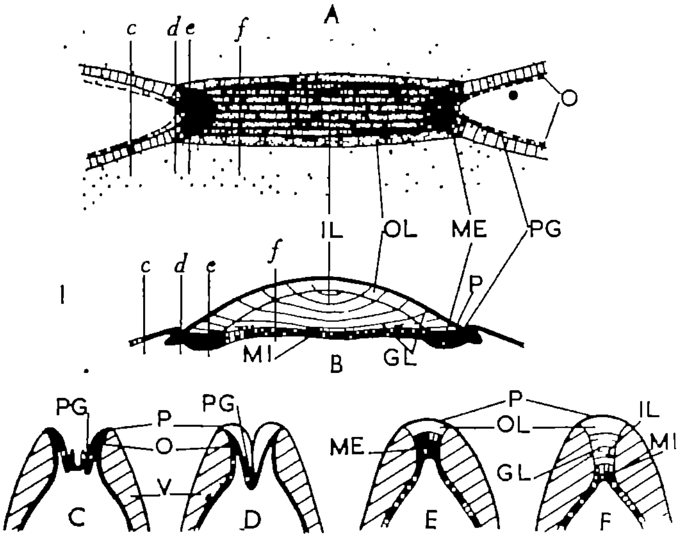

Fig. 1. Diagrams of primary ligament (*A*), viewed dorsally; (*B*), in sagittal section, (*C–F*), in transverse section, the positions being indicated by lines *c–f* in (*A*) and (*B*)
*GL*, growth lines, *IL*, inner layer of ligament, *ME*, outer lobe of mantle edge secreting 'outer' layer of the ligament; *MI*, mantle isthmus, *O*, outer lobe of mantle edge; *OL*, 'outer' layer of ligament; *P*, periostracum; *PG*, periostracal groove; *V*, valve
In *A* the extent of the periostracum is indicated by light stippling, the 'outer' layer by more dense stippling, and the inner layer by parallel lines

suture, conveying the erroneous suggestion that it represents the fusion of two originally separate pallial lobes. It is also proposed that the term 'ligament' should be used to include all structures linking the two valves dorsally. The structure and formation of the ligament can now be considered.

Like the rest of the mantle, the two ends of the isthmus are bounded by the mantle edge. This possesses here, as elsewhere, the capacity to secrete both periostracum and outer shell layers. Similarly, the epithelium of the isthmus retains the capacity to secrete inner shell layers. Thus the ligament primarily consists of a superficial periostracum and an 'outer' and an inner layer. These two layers, unlike those composing the rest of the shell, are largely uncalcified[3]. The results of the activities of these various zones of secretion are shown in Fig. 1. Fig. 1*A* represents a dorsal view, Fig. 1*B* a sagittal section, and Figs. 1*C–F* transverse sections through appropriate regions of such a ligament. The periostracum (*P*) is formed marginally and therefore extends, unchanged, over the ligament from each end. Secretion of largely uncalcified organic matter by the mantle edge (*ME*) in the depth of the embayments at the anterior and posterior ends of the isthmus (*MI*) results in the production of the 'outer' layer (*OL*) extending beneath the periostracum. The epithelium of the isthmus secretes the bulky inner layer (*IL*) of the ligament. Growth results in the extension of all three layers. Thus, although the sections represented in Figs. 1*C–F* are shown as having been taken from different regions of the same specimen, they could be interpreted equally well as having been taken, *at a constant distance from the umbones*, from different specimens at various stages of growth. Fig. 1*C* would then represent the youngest growth stage and Fig. 1*F* the oldest growth stage.

Fig. 2 represents a section through the margin of a valve. A comparison of this diagram with Fig. 1*B* reveals the identity of fundamental structure between valves and ligament (together constituting the shell). The periostracum (*P*) covers all regions of the shell although it is often worn away, especially over the ligament, the inner and 'outer' layers (*IL*, *OL*) of which are derived from the same origins as the inner and outer calcareous layers (*IV*, *OV*) of the valves. This is revealed by a comparison of the growth lines (*GL*) of the inner and 'outer' layers of the ligament with the corresponding layers of the valves. The lines of growth of the inner calcareous layers of the latter run parallel to the outer epithelium of the mantle and are continued into the outer calcareous layers to intersect the outer surface of the valve. The lines of growth of the inner and 'outer' layers of the ligament follow a similar pattern (Fig. 1*B*). They also run nearly parallel to the surface of the isthmus (*MI*) before continuing into the 'outer' layer to intersect its outer surface. Referring to the ligament, Mitchell[3] writes, "both layers appear to be of essentially the same composition as the organic matrix of the shell (conchyolin)". This is so because inner and outer layers of valves and of ligament represent local modification of the same two layers of the shell.

It should be noted that in some genera additional calcareous layers occur between the outer and inner layers of the valves, as in *Tivela stultorum*[4] and *Tellina tenuis*[5]. These additional layers are produced by "the less active part of the mantle edge" between "the extreme edge, where the growth is the most active" and the inner calcareous layer of the valves[4]. Weymouth[4] regards these intermediate calcareous layers as essentially extensions of the outer calcareous layers of the valves.

The structure of the ligament outlined above represents with reasonable probability the primitive condition, restricted to the region of the mantle isthmus and consisting of the three layers: periostracum, 'outer' and inner layers. This may be termed the 'primary ligament'.

This ligament probably originally extended from the anterior to the posterior adductor muscle, these being formed in the depth of the embayments by cross-fusion of the pallial muscles in these regions. Subsequent specialization has led to its reduction, and in this connexion conditions in the Lyonsiidæ[6]

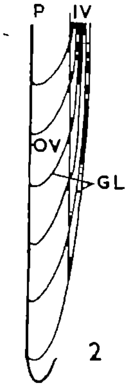

Fig. 2. Diagrammatic section through the edge of a valve
*IV*, *OV*, inner and outer calcareous layers. Other lettering as before

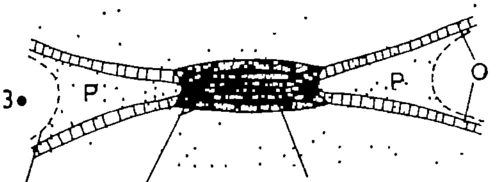
(*Lyonsia, Entodesma, Mytilimeria*) are of interest. Here the mantle isthmus is short and very characteristically formed; but the valves are united by a thick periostracum over the entire dorsal surface from the anterior to the posterior adductor. Such a condition, in which the inner and 'outer' layers of the ligament are reduced while the periostracum remains long, is indicated diagrammatically in Fig. 3. For reasons given below, the elongated periostracal layer in this ligament is more probably primitive than secondary.

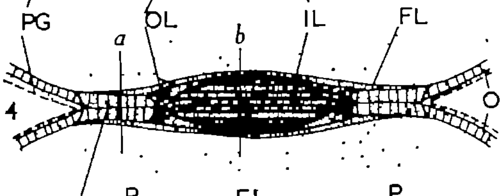
Following reduction in length, secondary extension can take place at either or both ends of the ligament. This is due to fusion of the mantle margins. Discussing the formation of siphons, it was shown by Yonge[7] that this may involve fusion (1) of the inner lobes only, for example, naked siphons of Tellinacea or Cardiacea; (2) of these with the middle lobes and periostracal grooves (now regarded by him as probably always associated), for example, siphons of Myidæ or Mactridæ, covered with periostracum; (3) of the outer lobes also, for example, siphons of *Cuspidaria*, encased in shell.

Fusion takes various forms, as will be discussed elsewhere by one of us (C. M. Y.). In the case of the periostracum, apparent fusion may result when the grooves are separated only by a low ridge representing the completely fused middle mantle lobes (that is, a condition somewhat intermediate between those shown in Figs. 1*C* and *D*). The secretions may then actually unite before spreading laterally over the surfaces of the valves. The periostracum can thus increase in extent and thickness with the growth of the animal; for example, in *Mya*, the fused surfaces remaining attached to the mantle tissues which secreted them. They do not represent additions to the ligament, the condition described in the Lyonsiidæ (Fig. 3) being for that reason probably primitive.

Fusion of the outer lobes of the mantle edge does, however, occur and causes secondary extension of the ligament. Such fusion (Figs. 4 and 5*A*, *FO*) has taken place, to greater or less extent, in many Lamellibranchia. It represents the coalescence of originally free mantle edges in very early post-larval life, after which all regions grow at relatively the same rate, with no further fusion of free surfaces. The result is the formation of a fourth layer in the ligament (described as layer "1*A*" and as "cover" by Trueman[2,8]). It represents material secreted by the united tissues (a true suture in this case) of the outer mantle lobes, as indicated in Figs. 4 and 5*A* and *B*. It is everywhere covered by periostracum (Fig. 5*A*), lying between this and the 'outer' layer in the region of the primary ligament (Fig. 5*B*). It is here proposed to call this the 'fusion layer' of the ligament (*FL*). It occurs without affecting the 'outer' or inner layers. It may be short or may extend for considerable distances beyond one or other end of the isthmus, usually posterior to this as in *Cuspidaria*[7] or in *Pinna* (as will be described elsewhere). In both these genera it extends to the extreme posterior end of the shell. This fusion layer contains a high proportion of organic matter and is similar to the 'outer' layer, although thinner. It generally shows growth-lines nearly parallel with its under-surface, indicating slow secretion over the full length of the fused epithelia.

In contrast to this secondary extension of the ligament is the reduction and possible final disappearance of the mantle isthmus, the two pallial lobes separating. This is what occurs in the Adesmacea, for example, in *Teredo* and *Zirphæa*, where there is no mantle isthmus and so no ligament, the valves being united solely by way of the adductor and, to a less extent, the pedal muscles.





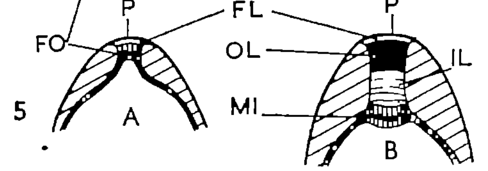


Fig. 3. Diagram of a ligament viewed dorsally, with a long (probably primitive) periostracal layer and relatively short 'outer' and inner layers. Lettering and shading as before

Fig. 4. Diagram of a ligament secondarily elongated as a result of fusion of the outer lobes of the mantle edge. *FL*, fusion layer, *FO*, fused outer lobes of mantle edge. Intermediate stippling indicates the extent of the fusion layer. Other lettering and shading as before

Fig. 5 (*A*, *B*). Transverse sections in areas indicated by lines *a*, *b* in Fig. 4. Lettering as before

Throughout the Lamellibranchia the ligament varies greatly in form. This is the result not only of the varying degrees of pallial fusion or separation but also of the growth pattern of the entire shell, the lines of growth of which radiate from nodes of zero or minimal growth represented by the umbones[9]. The position of the isthmus relative to the umbones therefore determines the growth pattern of the ligament. Primitively, the mantle isthmus probably lay between the umbones, and the amphidetic ligament extended during growth equally in both directions (Fig. 1). The isthmus may, however, be anterior or, more usually (for example, in *Tellina*), posterior to the umbones, with the formation, respectively, of prosodetic or opisthodetic ligaments.

In each group of Lamellibranchia the ligament is formed in a characteristic manner, being 'internal' or 'external', elongated or condensed, and with the primary and secondary constituents variously developed. No general description will cover all cases. In this article the mode of origin of the various layers composing the ligament has been described and suitable nomenclature suggested. It is hoped that this may lead to a clearer understanding of the nature of the ligament generally, and also aid in the comparative description of the many and very varied forms it may assume in different bivalves.

# LETTERS TO THE EDITORS

*The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications*

## Structure of Coenzyme A

CHEMICAL[1] and enzymic[2] studies from these two laboratories suggested that coenzyme A is best represented by formula (I) (cf. ref. 3). While the synthesis of various fragments of the molecule[4] has lent considerable support to this structure, the enzymic and chemical evidence did not agree on one point. This concerned the nature of a substance obtained by the action of nucleotide pyrophosphatase on the coenzyme and which stimulated the growth of *Acetobacter suboxydans*[5]. Although not isolated in a chemically pure state, it was thought to be a simple phosphate of pantothenic acid[6]. None of the synthetic pantothenic acid phosphates showed activity towards this organism; consequently, it was suggested[1] that this '*Acetobacter*-stimulatory factor' might be pantetheine-4′phosphate (II). An unambiguous synthesis of (II) is described here.

D : L-Pantetheine-O$^{2'}$ : S dibenzyl ether was prepared from pantothenic acid-2′benzyl ether by reaction with ethyl chloroformate and then 2-benzylthioethylamine. Phosphorylation with dibenzyl chlorophosphonate and removal of the four benzyl groups with sodium in liquid ammonia gave D : L-pantetheine-4′phosphate.

A more reliable method of assay for the '*Acetobacter*-stimulatory factor' consists in its resynthesis to coenzyme A by a partially purified enzyme system isolated from pigeon liver[7]. This system does not respond to pantetheine or to pantothenic acid phosphates. Synthetic D : L-pantetheine-4′phosphate, when examined in this system, showed an activity equivalent to 265 units of coenzyme A per milligram, which represents a 47 per cent conversion into coenzyme A. This is in excellent agreement with the expected 50 per cent conversion for the optically inactive substance.

Pure D(+)-pantetheine-4′phosphate, $[\alpha]_D^{18}$ 10·8°, was synthesized by direct phosphorylation of pantetheine with dibenzyl chlorophosphonate followed by removal of benzyl groups with sodium in liquid ammonia. This method, although ambiguous, is very convenient in operation, and the product showed a coenzyme A activity in the above test of 450 units/mgm., which represents an 82 per cent conversion. This synthesis establishes beyond doubt the structure of the pantetheine phosphate part of the coenzyme molecule, and it is hoped to extend these studies to the synthesis of pyrophosphates more closely related to coenzyme A.

## Activation of Enzymes by Chelating Agents

LYSINE and glyoxaline-4-5-dicarboxylic acid[1] and histidine[2] have been shown to activate preparations of Keilin horse-heart succinoxidase in unfavourable environments. A property common to these compounds is their ability to chelate heavy metals. We have accordingly tested the effect of other well-known chelating agents upon this system in bicarbonate buffer, which has been shown by Bonner[3] to depress its activity. In Table 1 are shown typical results.

Table 1

| Enzyme in | µl. oxygen/ 20 min. |
|---|---|
| Phosphate buffer (0·13 *M*) | 300 |
| Bicarbonate buffer (0·025 *M*) | 65 |
| ,, ,, + histidine (1·0 mgm./ml.) | 270 |
| ,, ,, + pyrophosphate (1·0 mgm./ml.) | 240 |
| ,, ,, + 8-OH-quinoline (0·1 mgm./ml.) | 300 |
| ,, ,, + versene (0·1 mgm./ml.) | 330 |
| Phosphate buffer + versene | 330 |

Each Warburg flask contained: 0·2 ml. enzyme (see ref. 3), 0·2 ml. cytochrome c, 2·4 ml. buffer (pH 7·3), 0·3 ml. activator to give final concentrations listed above, 0·2 ml. sodium succinate (0·4 *M*). Temp. 37° C., gassed with oxygen with phosphate buffer, and oxygen containing 5 per cent carbon dioxide with bicarbonate buffer.

The most effective reagent, versene (ethylenediaminetetraacetic acid), raises the activity in bicarbonate to a level even higher than that in optimum concentrations of phosphate. The activity in phosphate can be increased to the same figure by the addition of versene.

These results suggest that the activating effect of all these reagents is due to their ability to remove heavy metals from the reacting system. This suggestion is supported by the following further evidence: (1) If commercial sodium succinate is carefully purified, the activity in bicarbonate is markedly increased, and that in phosphate is raised a little (Table 2). However, the effect of versene is still marked, which is not surprising since succinate is not the only source of heavy metals in the system. (2) Concentrations of $2 \times 10^{-5}$ *M* cupric and zinc ions in phosphate buffer inhibit the succinic oxidase completely, and the activity is restored

Table 2

| Enzyme in | μl oxygen/20 min. Commercial sodium succinate | μl oxygen/20 min. Purified sodium succinate |
|---|---|---|
| Phosphate buffer | 300 | 324 |
| „ „ + versene | 330 | 440 |
| Bicarbonate buffer | 60 | 182 |
| „ „ + versene | 330 | 376 |

Conditions and concentrations as in Table 1

above the original by the addition of versene (Table 3). (3) In mitochondrial preparations carefully made with glass-distilled water and pure reagents, histidine no longer increases the activity in phosphate buffer[4].

Table 3 also shows that the well-known activation of the oxidase by calcium ions[5] and by aluminium or chromium ions[6] in the presence of phosphate is of the same order as that due to versene, and that the simultaneous presence of versene causes no further increase, but also no decrease. Keilin and Hartree ascribed activation by these reagents to a physical effect. They suggested that the insoluble precipitates formed by these metals could provide surfaces on which the oxidase could be 're-orientated'. However, the concentration of versene used here causes the rapid solution of the calcium and chromium ion precipitates but causes no diminution in activity. Calcium phosphate and the hydroxides of aluminium and chromium are known to be good adsorbents. An alternative explanation of the action of these precipitates is, therefore, that they strongly adsorb heavy metals. This may also explain the action of denatured globin, another well-known activator.

Table 3

| Addition to enzyme in phosphate buffer | μl. oxygen/20 min. No versene | μl. oxygen/20 min. Versene added* |
|---|---|---|
| None | 194 | 220 |
| $Cu^{++}$ $2 \times 10^{-[illegible]}$ $M$ | 18 | 215 |
| $Zn^{++}$ „ | 6 | 219 |
| $Ca^{++}$ „ | 230 | 228 |
| $Al^{+++}$ „ | 213 | 210 |
| $Cr^{+++}$ „ | 227 | 217 |

* 1·0 mgm./ml. final concentration

If heavy metals are as important as these experiments suggest, metal-binding by phosphate may explain the necessity for using high concentrations of phosphate with a Keilin horse-heart preparation compared with the small phosphate concentrations necessary in mitochondrial preparations. Concentrations of phosphate above the minimum probably act by binding heavy metals, and high concentrations are necessary to exceed the solubility product of the heavy-metal phosphates and cause their precipitation by mass action. The appearance of an optimum rather than a plateau may be caused by a direct inhibition of enzyme by phosphate at these very high concentrations. This inhibition may well become important before the full potential-activating effect of phosphate has been reached, so that versene may still raise the activity even at optimum phosphate concentrations.

## Paper Electrophoresis of Polyglutamyl Peptide

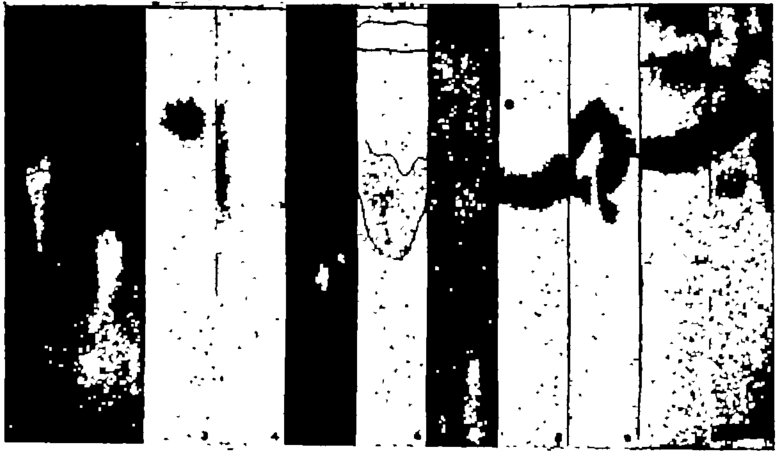
AFTER capsulated *B. anthracis* had grown in a modified synthetic medium of Brewer *et al.*[1], a mixture of growth products was isolated from the glass-filtered medium which gave a precipitate with copper sulphate. Crude polyglutamyl peptide was obtained from this precipitate[2]. An attempt was made to separate the components of the original mixture of growth products by paper electrophoresis using a tank as described by Flynn and Mayo[3], and it was found that the peptide could not be detected using naphthalene black, bromo-phenol blue, ninhydrin or ultra-violet light[4]. We found it could be detected by taking advantage of the acidic nature of the peptide, using the following technique: (1) paper strips with the peptide applied are run in a suitable buffer, for example, veronal/veronal sodium at pH 8·6 or acetic acid/sodium acetate at pH 4·5, and dried at 100°; (2) the buffer is washed out with two changes of 80 per cent ethanol; (3) the strips are treated with $N/50$ hydrochloric acid in 90 per cent ethanol; (4) the acid is thoroughly removed with ethanol; (5) after drying, the strips are dipped into $N/300$ alcoholic sodium hydroxide containing 0·04 per cent bromo-cresol purple, which is repeated if necessary until colour differentiation is obtained, and the strips are blotted.

The peptide appears as a bright yellow spot on a blue background. The method described by Reid and Lederer[5] for fatty acids was not suitable, since the background faded almost immediately and incorporation of formalin in the indicator solution caused proteins to give a faint acid reaction. Strips prepared as above were permanent for some days.

0·2 mgm. of two samples of the peptide, one obtained from the capsules of *B. anthracis*[6] and the other from the synthetic medium after growth and glass filtration, were applied to 3 cm. × 36 cm. strips of No. 4 Whatman paper and run in veronal buffer at pH 8·6 for 19 hr. using a 120-volt high-tension battery. The strips were treated as above and photographed (Figs. 1 and 2). The dye was eluted from one of the papers with ethanol and the peptide eluted with water and hydrolysed with 6 $N$ hydrochloric acid for 20 hr. The residue run on a paper chromatogram[7] showed only glutamic acid.

The mixture of growth products isolated from the synthetic medium was run in duplicate as before. One strip was stained by the naphthalene black method, differentiation being improved by including a wash in $N/100$ hydrochloric acid in 80 per cent methanol. The other strip was treated as above. Separation of the peptide from two components staining with naphthalene black had occurred; but in this case the peptide had travelled much faster (Figs. 6 and 7).

Artificial mixtures of the peptide and complete proteins gave rise to distorted pictures. With 70 μgm. of liver catalase and 150 μgm. of the peptide, a separation had occurred; but the catalase was repelled to the sides of the strip (Figs. 3, 4 and 5). Mixed with 200 μgm. of crystalline bovine albumin, 150 μgm. of the peptide moved at approximately the same rate but again appeared to repel the protein and be concentrated in the centre (Figs. 8 and 9). Similarly, when mixed with 10 μl. of normal human serum, all the protein components were distorted (Figs. 10 and 11).



In each paper strip the starting line is shown at the top (1) 0·2 mgm. of peptide from synthetic medium; 19 hr.; bromo-cresol purple. (2) 0·2 mgm. of peptide from organism; 19 hr.; bromo-cresol purple. (3) 0·07 mgm. of liver catalase; 19 hr.; naphthalene black. (4) 0·07 mgm. catalase + 0·15 mgm. peptide; 19 hr.; naphthalene black. (5) 0·07 mgm. catalase + 0·15 mgm. peptide; 19 hr.; bromo-cresol purple; (6) 1 mgm. growth products from synthetic medium; 19 hr.; naphthalene black. (7) 1 mgm. growth products from synthetic medium; 19 hr.; bromo-cresol purple. (8) 0·5 mgm. crystalline bovine albumin; 16 hr.; naphthalene black. (9) 0·5 mgm. albumin + 0·15 mgm. peptide; 16 hr.; naphthalene black. (10) 10 $\mu$l. normal human serum; 16 hr.; naphthalene black (11) 10 $\mu$l. serum + 0·15 mgm. peptide; 16 hr.; naphthalene black

These results suggest interaction between protein and polyglutamyl peptide, and we suggest this is a factor to be considered when electrophoresis is used as a method of separating unknown mixtures.

We should like to thank Dr. D. Herbert for helpful criticism. Acknowledgment is made to the Chief Scientist, Ministry of Supply, for permission to publish this letter.

## Effect of Calcium Chloride on Choline Esterase

The effect of salts on choline esterase activity has been studied by a number of investigators[1-13]. The results may be summarized as follows: (1) True choline esterase: salts with univalent or divalent cations inhibit at low concentrations of acetylcholine, whereas these salts activate at high concentrations of acetylcholine; the optimum substrate concentration is shifted to higher values, though this was not found by Augustinsson[13]. (2) Pseudo-choline esterase: salts with univalent cations inhibit, whereas divalent cations activate. In most experiments, hitherto, acetylcholine only was used as substrate, and choline esterase activities were determined manometrically,[9] thus introducing a possible complicating effect of bicarbonate and other buffers present in the system. An effect of the salts (especially at high concentrations) on the bicarbonate – carbon dioxide equilibrium cannot be excluded.

In the present communication, only the results with calcium chloride will be given, although preliminary experiments with other salts show that the effects observed are by no means specific for calcium chloride. They may be considered as general cation effects.

All enzyme activities were determined by the continuous titration method at $p$H 7·4 using a direct-reading $p$H meter[14] at 24° C. Spontaneous hydrolysis of the substrates was practically unaffected by the presence of even very high concentrations of calcium chloride and was taken into account in all experiments. The chlorides of the choline esters were used, with the exception of acetyl-$\alpha$-methylcholine and the acetyl-$\alpha$-$\beta$-dimethylcholines which were used as the iodides. The following enzyme preparations were used. *True choline esterase*: (1) a suspension of ox nucleus caudatus, prepared as described previously for rat brain[14] (crude true choline esterase); (2) Winthrop–Stearns choline esterase from ox erythrocytes (purified true choline esterase). *Pseudo choline esterase*: (1) Horse serum partially purified by Strelitz's method[15], as described previously[16] (crude pseudo-choline esterase); (2) horse serum purified as far as Strelitz's sixth stage (purified pseudo choline esterase).

Fig. 1 shows the effect of calcium chloride concentration upon the activity of crude true choline esterase and crude pseudo-choline esterase hydrolysing acetylcholine at a concentration of 0·01 $M$. In addition, a curve is shown for liver esterase (rat liver homogenate) hydrolysing ethyl butyrate at a concentration of 0·015 $M$.

While true choline esterase is activated by more than 100 per cent, pseudo-choline esterase activation only amounts to 20 per cent, whereas liver esterase is not activated at all. At high calcium chloride concentrations all three enzymes are inhibited.

In Fig. 2 is shown the effect of 0·1 $N$ calcium chloride and 0·1 $N$ sodium chloride on the acetylcholine hydrolysis of purified true choline esterase at

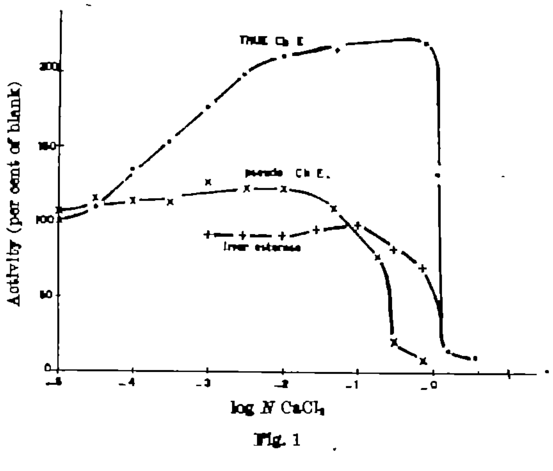

Fig. 1

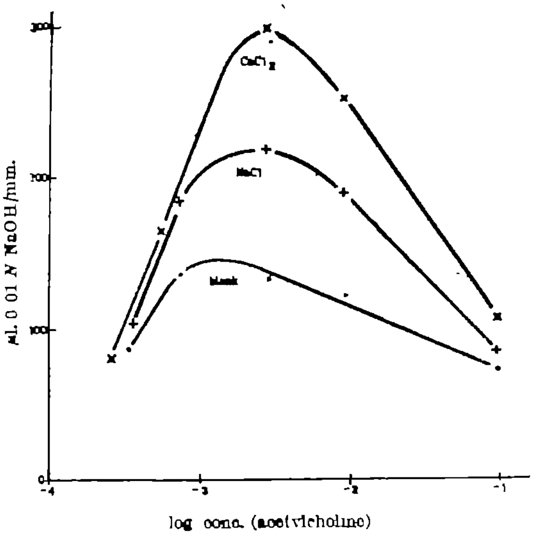

Fig. 2

varying concentrations of substrate. Activation is maximal at the optimum substrate concentration. No definite shift in this optimum is found, and this was confirmed in experiments with crude true choline esterase.

Table 1 shows the comparatively small effect of 0·1 *N*, 0·01 *N* and 0·001 *N* calcium chloride on the acetylcholine hydrolysis by crude pseudo-choline esterase. The activation increases slightly with increase of substrate concentration.

Table 1. EFFECT OF CALCIUM CHLORIDE ON THE HYDROLYSIS OF ACETYLCHOLINE BY CRUDE PSEUDO-CHOLINE ESTERASE

| Concentration of acetylcholine (*M*) | Concentration of calcium chloride (*N*) | % Activation |
|---|---|---|
| 1 | 0 1 | 20 |
| | 0·01 | 35 |
| | 0·001 | 29 |
| 0·1 | 0 1 | 19 |
| | 0·01 | 26 |
| | 0·001 | 10 |
| 0 01 | 0 1 | 13 |
| | 0·01 | 21 |
| | 0·001 | 25 |
| 0·001 | 0 1 | —19 |
| | 0·01 | — 6 |
| | 0·001 | 11 |

Table 2. EFFECT OF CALCIUM CHLORIDE ON THE HYDROLYSIS OF SUBSTRATES BY CRUDE TRUE CHOLINE ESTERASE AND CRUDE PSEUDO-CHOLINE ESTERASE*

| Substrate (0·01 *M* unless otherwise stated) | % Activation by calcium chloride (optimum concentrations in brackets) | |
|---|---|---|
| | True choline esterase | Pseudo-choline esterase |
| Acetyl choline | 129 (0 1 *N*) | 25 (0·01 *N*) |
| Propionyl choline | 105 (0·1 *N*) | 20 (0 01 *N*) |
| Butyryl choline | 90 (0 1 *N*) | 8 (0 01 *N*) |
| Benzoyl choline | not hydrolysed | 26 (0·01 *N*) |
| Acetyl-$\alpha$-methylcholine | 117 (0·1 *N*) | 16 (0·01 *N*) |
| Acetyl-$\beta$-methylcholine | 2 (0·01 *N*) | not hydrolysed |
| Acetyl-$\alpha,\beta$-dimethylcholine threo | 10 (0·01 *N*) | not hydrolysed |
| Acetyl-$\alpha,\beta$-dimethylcholine erythro | not hydrolysed | not hydrolysed |
| Butylacetate (0·028 *M*) | 113 (1 *N*) | 118 (0·1 *N*) |
| Isoamylacetate (0·0096 *M*) | 77 (1 *N*) | 101 (0·1 *N*) |
| 3,3 Dimethylbutylacetate (0 004 *M*) | 85 (1 *N*) | 76 (0·1 *N*) |
| Triacetine | 76 (1 *N*) | not hydrolysed |

* With the purified preparations the results were essentially the same, although the activations with the non-choline esters were somewhat lower.

The effects of calcium chloride on the hydrolysis of a number of substrates were compared. The results obtained for maximum activations taken from experiments with varying substrate and calcium chloride concentrations are shown in Table 2.

It is apparent that the optimum concentration of calcium chloride depends on the substrate and on the enzyme preparation used.

With pseudo-choline esterase the results can be summarized as follows. Uncharged substrates (non-choline esters) are hydrolysed and the hydrolysis is activated by calcium chloride. Charged substrates (choline esters) lacking a methyl group in the $\beta$-position are hydrolysed, but only slightly activated with calcium chloride. Charged substrates with a methyl group in the $\beta$-position are practically not hydrolysed.

With true choline esterase, uncharged substrates as well as charged substrates without a $\beta$-methyl group are hydrolysed, and this hydrolysis is activated by calcium chloride. Charged substrates with a $\beta$-methyl group are hydrolysed (with the exception of acetyl-$\alpha$-$\beta$-dimethylcholine (erythro)), but their hydrolysis is not activated by calcium chloride. Uncharged substrates with a methyl group next to the ester linkage (comparable with the $\beta$-position of choline) are under investigation. Preliminary experiments with pentanol-2-acetate suggest activation by calcium chloride of its hydrolysis by true choline esterase and practically no hydrolysis by pseudo-choline esterase.

A more extensive report and a discussion of the results will be published at a later date.

I am indebted to R. A. Oosterbaan and the Chemical Laboratory of the National Defence Research Council T.N.O. for preparing some of the substrates.

## Occurrence of Choline Oxidase in Plant Tissues

Mann and Quastel[1] showed that choline is oxidized to betaine aldehyde by homogenates of rat liver, and evidence was obtained that the betaine aldehyde so formed was further oxidized to betaine. Bernheim and Bernheim[2] showed that synthetic betaine aldehyde was oxidized to betaine at *p*H 7·8 by extracts of rat liver, but at *p*H 6·7 betaine aldehyde remained unchanged. As the result of further experiments, Mann, Woodward and Quastel[3] concluded that the choline oxidase system consists of choline dehydrogenase, cytochrome *c* and cytochrome oxidase. Muntz[4] has shown that betaine, formed by oxidation of choline, is an active donor of a labile methyl group for transmethylation in animal tissues. Although betaine is of widespread occurrence in plants, particularly in the Chenopodiaceæ, little is known of the mode of synthesis and the part played by this compound in the metabolism of higher plants.

Preliminary experiments which we have carried out have revealed the presence of an enzyme system in dialysed homogenates of young roots of sugar beet (*Beta vulgaris* Linn.) which brings about the oxidation of choline to betaine. The addition of cytochrome *c* facilitated the oxidation. The enzyme was inhibited by cyanide and inactivated by heat. The conclusion was reached that a choline oxidase system is present which bears a close resemblance to that of animal tissues.

The homogenate was prepared by grinding root tissues with sand in a mortar previously chilled, and straining through muslin to remove cell debris. The homogenate was dialysed against distilled water at 2° for 24 hr. To 12·5 ml. of the dialysed homogenate was added 12·5 ml. of an $M/5$ solution of phosphate buffer $pH$ 7·4, 12 mgm. of choline and 1·5 ml. of a solution of cytochrome *c* containing $1 \times 10^{-7}$ $M$/ml. After a period of 24 hr. at 20°, the $pH$ of the homogenate was adjusted to 4·5, protein was precipitated at 85°, removed by filtration and the filtrate clarified by heating with charcoal. After filtration, unchanged choline was precipitated with ammonium reineckate at $pH$ 8. The filtrate was brought to $pH$ 1 with hydrochloric acid and kept at 4° for 30 min. The copious precipitate which appeared was filtered off on a chilled sintered-glass crucible, washed with water-saturated ether, dissolved in warm water and recrystallized. The reineckate melted at 155°–156° and contained 12·2 per cent chromium. Pure betaine reineckate has a melting point of 154°–156° and requires 11·95 per cent chromium.

Homogenates previously heated to 100° and homogenates with added cyanide did not oxidize choline to betaine. Analysis of controls using homogenates without added choline and cytochrome *c* showed the presence of 0·7 mgm. residual betaine not removed by dialysis, as against 3·7 mgm. found in homogenates to which 12 mgm. of choline and cytochrome *c* had been added. Homogenates of young leaves of sugar beet were inactive under all conditions.

The conclusion is reached that betaine is formed in the root tissues of sugar beet by oxidation of choline and moves upwards into the leaves. Full details of these experiments will be published elsewhere. One of us (S. D. R.) is in receipt of a grant from the Agricultural Research Council.

## Inhibition of *E. coli* Strains by Amino-Acids

THAT amino-acids can inhibit growth of certain bacteria has been known for some time[1]. Thus Gladstone[2] showed that several strains of *Bacillus anthracis* which grew well on a synthetic amino-acid medium failed to grow when leucine or valine was added in concentrations as low as 1 μgm. per ml.; but a very small amount of leucine could abolish the inhibitory effect of valine and vice versa. A similar, though less marked, relationship was shown to exist between serine and threonine.

Washburn and Niven[3] have described analogous effects with a strain of *Streptococcus bovis* growing on a synthetic medium containing arginine as the only amino-acid. Addition of *iso*leucine or leucine in amounts of the order of 1 μgm. per ml. completely suppressed growth. Simultaneous presence of even smaller concentrations of valine would prevent this inhibition.

I wish to record a similar effect with strains of *Escherichia coli*. In the course of auxanograph tests, it was found that the *K*12 strain growing on the minimal medium of Davis and Mingioli[4] was specifically and strongly inhibited by DL- or L-valine. This inhibition was completely reversed in the presence of DL-leucine or DL-threonine. In liquid minimal medium, as little as 1 μgm./ml. of valine suppressed growth for 24 hr., and the inhibition caused by 90 μgm./ml. of valine could be prevented by the simultaneous addition of 15 μgm./ml. of leucine or 8 μgm./ml. of threonine.

In order to see whether this is a general phenomenon among *E. coli* strains, the same technique of testing was applied to a miscellaneous collection of one hundred *coli* strains selected from routine plates for their ability to grow on the minimal medium. Not one further strain was inhibited by valine; but a surprising number of other inhibitions came to light. Thus ninety strains were inhibited in varying degrees by *nor*leucine, seventy-five by *nor*valine, nine by serine, seven by α-amino butyric acid, five by aspartic acid, five by histidine, three by cystine, two by lysine, one by leucine and one by tyrosine. Some strains were obviously inhibited by several amino-acids, others only by one. In every case reversal of the effect was possible by simultaneous presence of one or more different acids, the commonest reversers being leucine and methionine.

This agrees with the finding of Porter and Meyers[5], who reported that inhibition of *Proteus morgani* strains by *nor*leucine or *nor*valine could only be consistently prevented by methionine. This contra-inhibitory effect in *E. coli* is, however, by no means confined to methionine and leucine; for example, inhibition of one strain (61) by aspartic acid could be reversed by valine, with another strain (89) by valine, proline and glutamic acid; inhibition of strain 28 by serine was prevented by aspartic acid or α-amino butyric acid but not by leucine or methionine. By following the growth of these strains in liquid medium, it was observed that the inhibition consisted of an increased lag of up to 24 hr. duration; eventually the populations on minimal media with or without an inhibiting amino-acid reached the same density.

These phenomena are quite distinct from the reported[6,7] inhibition of *Escherichia coli* by D-amino-acids such as D-leucine and D-valine at concentrations of about 1–5 mgm./ml. The toxic effect of these relatively high concentrations of D-amino-acids is exhibited in nutrient broth, whereas all the other inhibitions described above are completely reversed in the presence of nutrient broth.

## Protoporphyrin in the Integument of *Asterias rubens*

MACMUNN in 1886[1] extracted the integument of *A. rubens* (then known as *Uraster rubens*) with ethyl alcohol containing sulphuric acid. The extracts were red-fluorescent to ultra-violet light, and MacMunn reported the presence of hæmatoporphyrin in them—the only porphyrin then known, having been discovered by Hoppe-Seyler in 1871[2]. So far as we know, there is no further mention of hæmatoporphyrin in *Asterias* in the literature.

As part of a survey of marine animals from the point of view of porphyrin content, *Asterias rubens* has been re-investigated by us, when it was found that the integument contained free protoporphyrin and not hæmatoporphyrin.

The details of this work will be published elsewhere, but the essentials are as follow. The integument was freed from adhering cæca, chopped fine, and extracted by shaking with a 5 : 1 mixture of peroxide-free ether and glacial acetic acid, with addition of 1/10 volume of petroleum ether to avoid emulsion formation. After washing out most of the acetic acid with water, the porphyrin was extracted with 5 per cent w/v hydrochloric acid, and driven back to peroxide-free ether with sodium acetate. The ether solution was washed, evaporated to dryness, and the residue rinsed with petroleum ether. The dry residue was dissolved in chloroform, from which the porphyrin was flocculated by adding petroleum ether.

The porphyrin was purified by esterification with methanol saturated with hydrochloric acid, and chromatographed on magnesia from chloroform solution[3]. Impurities remained at the top of the column as a dark brown band, and a strong violet-red band formed some 2 cm. below. This band was eluted only by 3 : 100 methanol–chloroform, indicating protoporphyrin ester. The porphyrin ester crystallized from chloroform/methanol in red prisms, melting at 225° C. (uncorr.).

Evidence of identification of the porphyrin is as follows.

(1) Methyl ester crystallizes in red prisms melting at 225° C. These gave a mixed melting point of 225° C. with a sample of protoporphyrin IX dimethyl ester (melting point 226° C.) made from blood.

(2) Absorption spectrum (Hartridge reversion spectroscope) in chloroform :

| | I | II | III | IV | |
|---|---|---|---|---|---|
| *Asterias* porphyrin | 630 | 575 | 540 | 507 | mμ |
| Protoporphyrin IX dimethyl ester (blood) | 631 | 575 | 541 | 507 | mμ |

(3) Paper partition chromatography using a lutidine–water system in an atmosphere of ammonia vapour. The free porphyrin gave one spot only, of $R_F$ value 0·8, indicating a dicarboxylic porphyrin[4].

(4) Elution of the methyl ester from magnesia by 3 : 100 methanol–chloroform indicated protoporphyrin.

(5) Reduction of the methyl ester by hydriodic acid and subsequent esterification gave mesoporphyrin IX dimethyl ester (melting point 215° C.). Therefore, the original porphyrin could only be protoporphyrin IX, a type-III porphyrin derived from ætioporphyrin III[5].

(6) Chu's test 1946—adding a few drops of concentrated hydrochloric acid to a chloroform solution of the porphyrin—gave a green colour, suggesting protoporphyrin.

Fluorimetric estimation of the protoporphyrin[6] in the integument of various colour groups of *Asterias* gave the following mean contents :

| Violet-brown group | Red group | Pale group |
|---|---|---|
| 69·1 μgm./gm. | 16·0 μgm./gm. | 5·0 μgm./gm. |

## Dehydrogenation of Various Substrates by *Vibrio choleræ*

A DETAILED investigation of the enzyme make-up of *Vibrio choleræ* has been undertaken with the view of studying the metabolic activities of the pathogen. Deamination of amino-acids by a few strains of *Vibrio choleræ* has been reported elsewhere[1]. This communication covers preliminary observations on the dehydrogenase activity of an Ogawa strain (No. 49514—Kasauli), and the Inaba and the Rough variants derived from it[2].

Twenty-four hour growth of the organism on agar slopes ($p$H 8·0) was harvested with saline (0·85 per cent sodium chloride for Ogawa and Inaba and 0·3 per cent sodium chloride for Rough) and, after centrifugation, washed once with salt solution of appropriate concentration and recentrifuged. The residue was finally suspended in saline and adjusted to a fixed turbidity value using a Lumetron model *A* photo-electric colorimeter. The nitrogen content of the suspension was determined in an aliquot portion by the micro-Kjeldahl procedure. The reaction mixture, consisting of 1 ml. of $M/100$ substrate, 1 ml. of $M/15$ phosphate buffer of $p$H 8·0 and 1 ml.

DEHYDROGENATION OF VARIOUS SUBSTRATES BY *Vibrio choleræ*

* Decolorization was not complete.

of $M/10,000$ methylene blue, was kept in the main compartment of a Thunberg tube. 1 ml. of the bacterial suspension was taken in the hollow stopper. The tubes were evacuated with a high-vacuum pump, equilibrated at 38° C. for 5 min. and then mixed. The time taken for the complete discharge of the blue colour was taken as the end-point. Results of some typical experiments (two sets of triplicates) on a few substrates are given in the accompanying table.

It is evident that almost all the amino-acids and aliphatic acids employed in the present study act as hydrogen donors for the respiratory activity of this organism. Ethyl alcohol and malic acids were, however, found to be resistant to dehydrogenation. It may be inferred from the results that the dehydrogenases of *Vibrio choleræ* are linked up with cytochrome systems reported[2] to be present in these organisms. However, the possibility of other coenzyme systems taking part in this process cannot be excluded.

In control experiments with water in place of substrate there was no discharge of colour up to 18–20 hr.

The results obtained would indicate that dehydrogenation by *Vibrio choleræ*, based on activity, falls into three main groups, namely,

Group *A* : Rough > Inaba > Ogawa
Group *B* : Rough > Inaba ~ Ogawa
Group *C* : Rough ~ Inaba > Ogawa

This is in contrast to the pattern observed in deamination wherein the activity was of the order Ogawa–Inaba–Rough[4].

Barron[5] has shown that when the regulatory mechanism within a cell is progressively blocked by the controlled use of alkylating or thiol reagents, catabolic reactions proceed at a faster rate, resulting in an increase in cellular respiration. A faster rate of dehydrogenation in the converted variants (Inaba and Rough) now observed would therefore indicate a higher metabolic activity.

The conversion of the Ogawa into Inaba and the Rough has been considered to be a loss variation[3]. Against the background of the work of Barron[5], it would appear from the present investigation that some factor present in the parent cell is lost during the transformation.

## Anti-diuretic and Oxytocic Substances liberated by the Digestion of Plasmatic Proteins with Pepsin

DIGESTION of human, ox and horse plasma or digestion for 5 hr. at 37° C. of hypertensinogen (alpha-2 globulin) at $p$H 2·5–3·5 with crystallized pepsin (50 mgm. per litre) leads to the liberation of several peptides. These substances have been shown to have similar pharmacological effects to those produced by neurohypophysial extracts. Croxatto and Croxatto[1] have demonstrated that digestion of hypertensinogen with pepsin produces, under certain conditions, pepsitensin. The latter substance behaves similarly to hypertensin with regard to the action of proteolytic enzymes and tissue extracts.

Hydrolysis of hypertensinogen or a second hydrolysis (with pepsin at $p$H 2·5) of the extracts which contain pepsitensin produces a substance which lacks any hypertensive effects but shows instead an intense anti-diuretic action in water-loaded rats (Burn's test). The substance shows chemical and pharmacological properties which are similar to those of vasopressin after being treated with sulphydrilic substances[2].

The sulphydrilic compounds used were thiosorbitol and thioglycollate, but mainly the former. The concentration of thiosorbitol used was 0·003–0·012 $M$ ($p$H 7·3, period of contact 6–12 hr., temperature 37°). Under these conditions, it can be shown by means of intravenous injections that the hypertensive (vasoconstrictor) effect of the vasopressin is destroyed and the antidiuretic potency is totally conserved or almost so. The effect of thioglycollate did not differ from that of thiosorbitol, though at the same concentrations a greater destruction of the antidiuretic properties was produced than with thiosorbitol.

The anti-diuretic substance liberated by pepsin is soluble in both methyl and ethyl alcohol and also in acetic acid. It is also adsorbed by 'Norit', from which it is easily eluted with acetic acid. Afterwards, it is easily precipitated by adding a mixture of equal parts of petroleum ether and absolute alcohol. Also, it may be precipitated by adding either ether or benzol. It is not destroyed by boiling in an acid environment. It is not precipitated by adding trichloroacetic acid. Also, it can be dialysed through 'Cellophane' membranes. It resists the prolonged action of pepsin, but it is destroyed by chymotrypsin.

The anti-diuretic substance is not produced by a simple acid hydrolysis of plasma (pH 2·5) obtained by adding hydrochloric acid to plasma proteins.

The substance is capable of inhibiting diuresis of hypophysectomized rats with diabetes insipidus when injected intravenously or intraperitoneally. Its action on diuresis of the cat anaesthetized with 'Dial' is similar to that of vasopressin treated with thiosorbitol. Extracts adsorbed by 'Norit', eluted with acetic acid and precipitated with ether, produce (at a dose of 10 mgm. in a rat of 200 gm.) in the hyperhydrated rat an effect that is comparable to that of 500–1,000 μ of vasopressin.

It is possible to identify in the same extracts another substance which has marked oxytocic effects and which acts on the uterus of both guinea pigs and rats. This substance is destroyed by chymotrypsin, but resists the action of crystallized pepsin and trypsin. When hypertensinogen is treated previously with renin, in order to eliminate the production of hypertensin, it produces (after further digestion with pepsin) an increase of the anti-diuretic factor and a decrease of the oxytocic factor. Several tests with the different fractions separated from the hydrolysed hypertensinogen demonstrate that the oxytocic and the anti-diuretic effects are independent. This fact suggests that they are different substances.

It is evident that hypertensinogen potentially contains certain peptide fractions which are liberated by hydrolysis with pepsin. These fractions have pharmacological effects which are similar to those of hypertensin and those of the oxytocic and anti-diuretic hormones.

These facts confirm previous deductions about the chemical similarity of hypertensin and of the hormones from the neurohypophysis[3] and suggest that probably the hormones from the hypophysis are bound to certain blood proteins. Another possibility would be that proteins contain some chemical precursors which would be utilized by the hypophysis in the synthesis of hormones[4].

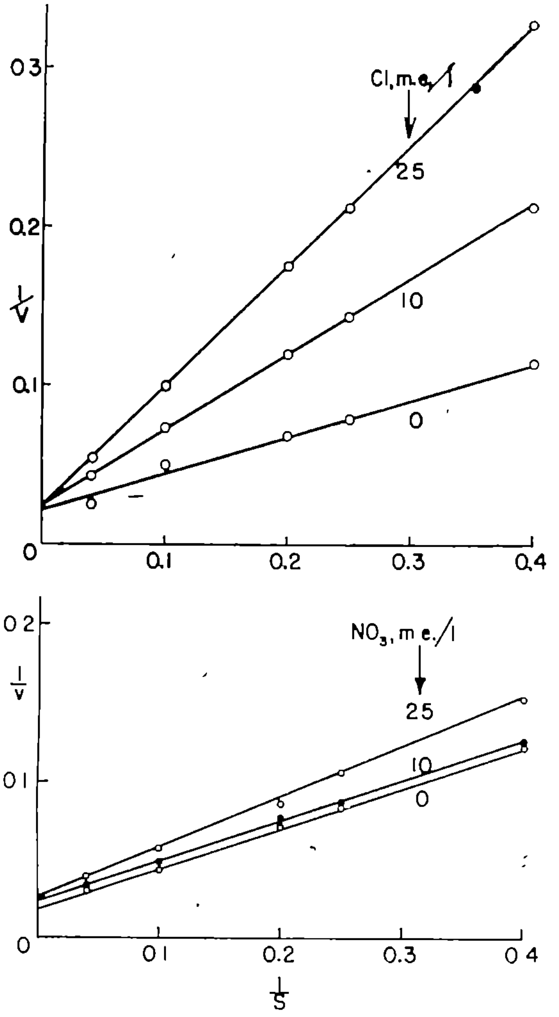
## Mechanism of Ion Absorption by Roots

THE absorption of anions by barley roots has been studied in a manner similar to that adopted in a recent study[1] of the absorption of alkali cations. The earlier paper considered the effect on the rate of absorption of varying (1) the concentration of the ion whose absorption was being measured (arbitrarily called the 'substrate ion'), and (2) the concentration of another alkali cation present (the 'interfering ion'). The anion was chloride throughout. The results were shown to be consistent with the view[2,3] that the absorption of potassium and rubidium involves the formation and subsequent breakdown of an intermediate labile complex, *MR*, of the cation, *M*, with an ion-binding carrier, *R*. It was assumed that a membrane impermeable to the free ions is traversed by *MR*. Upon arriving at the inner surface, *M* is released through a chemical change in the carrier, *R*.

This scheme of the formation and subsequent breakdown of a complex is analogous to the accepted mechanism of enzyme action, which assumes the formation of an intermediate labile complex, *ES*, of the substrate, *S*, with the enzyme, *E*. The kinetic treatment of enzymatic reactions based on this assumption[4,5] was shown to be applicable to ion transport. It was found that potassium and caesium interfere competitively with absorption of rubidium, indicating identical binding sites on the carrier, *R*, for these three ions. Sodium (except at relatively high concentrations of rubidium or sodium) and lithium did not interfere competitively with absorption of rubidium, indicating different binding sites.

The mechanism outlined in the earlier paper[1] and briefly indicated above has now been found to apply in the absorption of anions as well. The methods, in all essentials, were those already described[1]. Briefly, seeds of the Sacramento variety of barley were germinated in aerated water for 24 hr. in the dark, following a 20-min. treatment with 10 per cent hydrogen peroxide to improve germination. The seedlings were grown for five days in the dark at 24° C., over a solution of $10^{-4}$ *M* calcium sulphate, which was renewed once during that time. The roots were then excised and used in the absorption experiments under the following conditions: roots, 1·00 gm. fresh weight per sample; volume of solution, 50 ml.; temperature, 30° C.; duration, 3 hr. The cation was potassium throughout.

The 'substrate ion', the rate of absorption of which was being measured, was bromide tagged with bromine-82. Its concentration, *S*, was varied from 2·5 to 25 m.equiv./litre, both in the presence and absence of chloride and nitrate as interfering ions. The rate, *v*, of absorption of bromide was expressed as m.equiv./3 hr. Upon plotting the reciprocal of the absorption rate, $1/v$, against the reciprocal of the substrate concentration, $1/S$, according to Lineweaver and Burk[6], straight lines are obtained (see diagram). When the interfering ion is chloride, the slopes of these lines are increased, with little or no change in the ordinate intercepts, indicating competitive interference, that is, identical binding sites. With nitrate as the interfering ion, all other conditions being identical, the line for nitrate = 10 m.equiv./l. is parallel to that obtained in the absence of interfering ions. This is characteristic of 'un-competitive' interference (cf. Wilson[7]), which involves combination of the interfering ion with the carrier-ion complex, *RA*, at a site different from that which binds the substrate ion, bromide. At the higher concentration of nitrate (25 m.equiv./l.) both slope and intercept increase, the slope by a smaller factor than the intercept. This case is intermediate between 'un-competitive' and 'non-competitive' interference: the interfering ions combine with *RA*, and to a smaller extent with free *R* as well, at sites different from those with which the substrate combines. The 'Michaelis constants' $K_{\mathrm{Br}}$, which denote the affinity of the bromide ion for the



Double reciprocal plot of interference by chloride and nitrate with absorption of bromide

binding site, were 11·00 and 14·22 m.equiv./l. in the experiments plotted in the graph. The constants, $K_{Cl}$, for chloride found were 12·57 and 13·42 m.equiv./l. at 10 and 25 m.equiv./l., respectively. Hence, the affinity of bromide and chloride ions for the binding-site of the halides is essentially the same.

According to the theory of salt transport advanced by Lundegårdh[7], there is a fundamental difference in the mechanism of cation absorption and anion absorption: "An active accumulation of anions produces potentials which attract cations". The absorption of anions, unlike that of cations, is a primary metabolic process mediated by a component of the respiration referred to as "anion respiration". "The anion respiration thus acts as the promoter of salt accumulation even if the cations are more passively dragged through the protoplasm".

It seems doubtful whether the present findings, together with the earlier ones[1] concerning the absorption of alkali cations, can be reconciled with this dual view. The results imply that cations as well as anions are accumulated by a mechanism involving their temporary combination with binding compounds. Instead of following "general principles of exchange-power, well known from soil colloids", the affinity of cations (as well as of anions) for the various binding sites is governed by their chemical characteristics. It would seem, in fact, that all active transport of ions must needs implicate their combination with protoplasmic constituents, and that this forms the chemical basis for selectivity.

This research was supported in part by the U.S. Atomic Energy Commission.

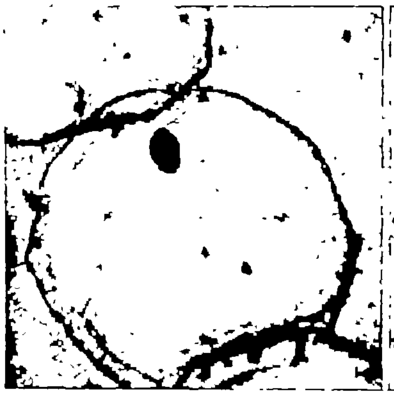
## Nature of Heinz Bodies

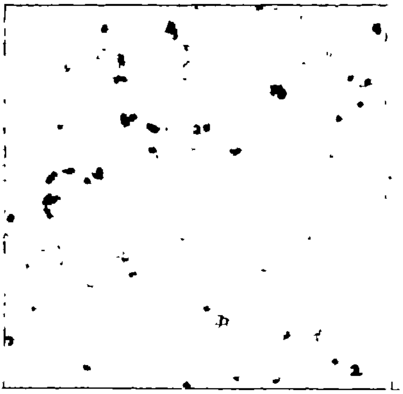
A great number of hæmolytic agents have been found to produce, besides methæmoglobinæmia, certain highly refractive inclusion bodies, the so-called 'Heinz bodies', in the erythrocytes[1]. The connexion between methæmoglobin and Heinz bodies, however, is not clear. Most agents producing Heinz bodies belong to the group of aromatic amines and include such important drugs as sulphonamides and thiosemicarbazones[2,3]. The reports on the formation and chemical nature of Heinz bodies are contradictory[4]. There are reports indicating that these bodies consist of iron-containing compounds[5–7]. Recently it has been stated that[8] Heinz bodies are identical with denatured globin, isolated by Warburg *et al.*[9] from blood in phenylhydrazine poisoning. This conclusion has since been attributed erroneously[4] to Warburg *et al.*

Electron micrographs made of erythrocytes containing Heinz bodies, however, cast some doubt on the latter interpretation. Thus, the inclusion bodies appear as unusually opaque structures (Fig. 1), similar to those shown by Jung[10] earlier. The electron micrographs strongly suggest that the Heinz bodies contain atoms heavier than those contained in globin. Therefore, a separation of Heinz bodies from the denatured globin was undertaken.

Cats were given 30 mgm. aniline per kgm. body-weight in 0·9 per cent sodium chloride intravenously. The development of Heinz bodies within the erythrocytes was followed by the electron microscope in order to observe their first appearance. Blood smears were prepared on glass slides before injecting the aniline, and at intervals up to four days after the injection. The smear was covered with a 'Formvar' film and floated off on to water. After hæmolysis it was transferred on to the grids and examined in the electron microscope. This procedure should remove the denatured globin from the corpuscles since, according to Warburg, hæmolysis frees denatured globin from erythrocytes[9].

Shortly following the injection of aniline, one or two black, irregular bodies, about 0·1–0·2 μ in diameter, appear in approximately one-third of the erythrocytes. The incidence of these bodies and their size apparently increase, so that after 24 hr. almost all the erythrocytes contain one, or occasionally two large, black Heinz bodies. The bodies range in size from 0·5 to 1 μ and have a marginal position.





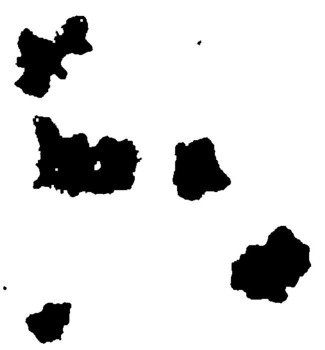


Fig. 1. Electron micrograph of a hæmolysed erythrocyte containing a Heinz body. (× 5,200)
Fig. 2. Isolated Heinz bodies stained with gentian violet. Light microscope. (× 1,000)
Fig. 3. Isolated Heinz bodies. Electron micrograph. (× 6,700)

For the isolation of the Heinz bodies, about 40–50 ml. of blood were drawn from the heart of an animal anæsthetized with nembutal, and heparinized. The chilled blood was centrifuged and the corpuscles were washed twice in 0·9 per cent sodium chloride and hæmolysed with 20 volumes of distilled water. The insoluble matter—which includes the denatured globin at neutral *p*H[8] and which imparts marked turbidity to the suspension—was washed repeatedly with distilled water in the centrifuge until colourless. In the last washing, the sediment was stirred rapidly in a small amount of distilled water to destroy the membranes completely and then was centrifuged at 1,000 *g* for three minutes. At this point a greyish, very heavy precipitate sediments first. The heavy fraction was separated from the overlying bulk of the precipitate, and both were taken up in ten volumes of 0·1 *N* hydrochloric acid.

Most of the insoluble matter other than the rapidly sedimenting fraction went into solution in 0·1 *N* hydrochloric acid, as does denatured globin[9]. This solution, separated from the insoluble material, gave a precipitate when neutralized. Neither the bulky fraction separated from the heavy fraction nor the precipitate formed after neutralization of the acid solution showed Heinz bodies when stained with gentian violet. Moreover, no structure was apparent in these preparations possessing such a high degree of opacity as the Heinz bodies in the electron micrographs.

The heavy, grey precipitate remained insoluble in 0·1 *N* hydrochloric acid. This precipitate was washed several times with the same acid and finally in distilled water. It showed innumerable bodies in the light microscope (Fig. 2), which stained characteristically with gentian violet; and it revealed typical bodies in the electron microscope (Fig. 3), which were identical with the Heinz bodies observed within the erythrocytes. The heavy, grey precipitate dissolves in 0·1 *N* sodium hydroxide. The ultra-violet absorption spectrum of this alkaline solution (Fig. 4) is not that of a pure protein such as globin. The absorption at 280 mμ is indicative of a small amount of protein which may be present as an integral part of the Heinz body or as a contaminant. Gross *et al.*[5] previously found iron in a fraction identified as Heinz body material, and we have confirmed this, using 2.2′-dipyridyl. Although some reservation exists because of the great sensitivity of the dipyridyl reaction, the presence of iron would account for the high opacity of Heinz bodies seen in the electron micrographs. Therefore it is concluded that the grey precipitate consists of Heinz bodies which are distinct and separable from the denatured globin.

## Rates of Combustion of Solid Fuel Particles

DURING the combustion of liquid fuel drops, the chemical oxidation occurs in the vapour phase. The rate-controlling process is thus the transfer of the heat necessary for the evaporation of the drop[1].

In the case of solid fuel particles, the primary combustion occurs at the surface of the particles. If the surface temperature is high enough (experimental evidence published by Tu, Davis and Hottel[2] suggests a threshold temperature of about 850° C.), the rate of the gas–solid reaction is so high that the chemical resistance is negligible, and thus the rate-determining process is the rate at which oxygen is transferred through the gas film surrounding the particle.

Methods of calculating this mass transfer-rate have been proposed by several authors, making use of the analogies between fluid friction, heat transfer and mass transfer[2,3]. It should be emphasized here that in calculating the fluid friction it is only the skin friction component of the total drag that is of significance. Furthermore, in cases in which a laminar boundary layer exercises a controlling influence, the simple turbulent flow forms of the analogies need modification by a function of the Prandtl number in the case of heat transfer[4] and of the Schmidt number in the case of mass transfer[5]. In cases where the Prandtl and Schmidt numbers approach unity, as can occur in gas-phase systems, these modifications may, in fact, be numerically small.

Some notes have been written recently by Edmondson[6], making particular reference to the equations based on Reynolds's analogy proposed by Silver[3] for the combustion-rates of solid particles, and presenting an analysis in these terms of published experimental results. Some reference was made in Edmondson's notes to the influence of laminar conditions, but the equations as applied were those based on the original form of Reynolds's analogy appropriate to the turbulent flow range.

However, rather than making use of the analogies between fluid friction, heat transfer and mass transfer, there is a more direct method of undertaking the calculation for the case of individual particles. There are already available several theoretical and experimental results on the transfer of mass to and from spherical surfaces. In particular, Froessling[7] has presented a semi-empirical equation expressing the mass transfer as a function of the Reynolds number and the Schmidt number. The range of Reynolds numbers examined experimentally was from 2 to 800.

It is suggested in the present communication that Frössling's equation be used, with appropriate values of the physical constants, for calculating the transfer of oxygen to burning spherical solid surfaces and hence the burning-rates.

For example, for carbon spheres in air, assuming that the main primary product of the heterogeneous reaction is carbon monoxide[8,9], it can be shown that the reaction-rate at a representative mean gas-film temperature of 1,200° C. may be expressed by the non-dimensional equation:

$$F = 0{\cdot}347\ (1 + 0{\cdot}272\ Re^{1/2}).$$

In this equation, $Re$ is the Reynolds number, and $F$, a non-dimensional reaction-rate factor, is equal to $Sd/\rho D$, where $S$ is the specific reaction-rate at the surface of the sphere (gm. sec.$^{-1}$ cm.$^{-2}$), $d$ is the diameter of the sphere (cm.), $\rho$ is the density of the gas (gm. cm.$^{-3}$), and $D$ is the coefficient of diffusion of oxygen in the gas (cm.$^2$ sec.$^{-1}$).

It may be noted that the value of the numerical factor 0·347 in the above expression for $F$ is directly proportional to the partial pressure of oxygen in the free gas stream. Over the range of at least 800°–1,400° C. at any given Reynolds number, the influence of the gas-film temperature on the numerical form of the above non-dimensional equation for $F$ is slight.

Comparison of theoretical values of the rates of burning calculated in this manner with published experimental measurements on the rates of burning of carbon spheres[2,10] shows evident agreement. This being so, the theoretical equation may be used to calculate in particular the effects of Reynolds number and partial pressure of oxygen on the rates of combustion.

## Effect of Irradiation on the Intensity Distribution of the Second Positive Nitrogen Bands excited in a Nitrogen Ozonizer

MORE exact measurements have now been made of the changes in the relative intensities of several bands of the second positive system of nitrogen, brought about by irradiation with the 3650–3660 A. group of mercury radiations, using an ozonizer discharge tube excited under conditions yielding the maximum negative Joshi effect when the pressure of the gas is 20 mm. These confirm, in general, the results of preliminary investigations[1] and show further that the percentage decreases of intensity are in the following order of bands:

In sequences: (1,4) > (0,3); (1,3) > (0,2)
In progressions. (0,3) > (0,2) > (0,1); (1,4) > (1,3).

The results show that a change in the relative intensity distribution of the second positive bands of nitrogen is thus brought about, not only in sequences but also in progressions.

A detailed study of the band systems and their intensities developed in the ozonizer tube, excited as above, has revealed that the excitation of the nitrogen molecule is brought about not only by electron collisions but also that collisions with particles of atomic or ionic masses play an important part[2]. Since the variations in electron collisions are less likely than those of atomic or ionic collisions to bring about an alteration in the relative intensity distribution of these bands[3], the present results, in the case of sequences, show that the atomic or ionic collisions are affected by irradiation. Further evidence on this point is afforded by the observation in the present investigation that external irradiation alters the intensity distribution of the bands in a manner similar to the substitution of air for nitrogen as recorded in experiments[4] on low-pressure induction-coil discharges through nitrogen and air.

The effect observed in the two progressions has to be attributed to an induced perturbation of the low $v''$ levels brought about by irradiation. A somewhat similar perturbation of these levels brought about by changes in discharge conditions has been observed in the first positive system of bands by Kaplan[5] and others[6].

Details are being submitted for publication elsewhere.

## Microwave Spectrum and Structure of Iodosilane

IT has come to our notice that independent studies of pure-rotation spectra of the symmetric-top molecule $H_3SiI$ have been made in our two laboratories. The $J = 2 \rightarrow 3$ and $J = 3 \rightarrow 4$ transitions of $H_3{}^{28}SiI$ were observed at Schenectady with a Stark modulation microwave spectrograph, and the $J = 3 \rightarrow 4$, $J = 4 \rightarrow 5$ and $J = 5 \rightarrow 6$ transitions were observed at Birmingham with a microwave spectrograph of the 'video' type operating between about 20,000 Mc./sec. and 40,000 Mc./sec. Good agreement exists between the results of the two investigations. The hyperfine structures of the spectra can be well fitted to patterns calculated for the nuclear quadrupole coupling of the iodine nucleus, second-order effects being allowed for[1]. For $H_3{}^{28}SiI$, $B_0$ is 3,215·6 Mc./sec., the corresponding moment of inertia, $I_B$, is $260{\cdot}90 \times 10^{-40}$ gm.cm.², and the nuclear quadrupole coupling factor, $eqQ$, for $^{127}I$ is $- 1{,}240 \pm 30$ Mc./sec.

If we assume the Si—H distance to be 1·55 A., and the angle H—Si—H to be 111°, which is a configuration for the $SiH_3$ group close to that found in $H_3SiCl$ [2] and $H_3SiBr$ [3], the Si—I distance in iodosilane is found to be 2·433 A. This result is not very sensitive to reasonable variations in the assumed parameters; for example, the calculated length of Si—I is increased by only 0·004 A. if the angle H—Si—H is increased by 2°, or if the Si—H bonds are shortened by 0·04 A. The Si—I distance found agrees with that reported[4] in $SiI_4$ by electron diffraction, which appears to be the only previously determined length for such a bond. The length found is slightly less than that predicted by the Schomaker–Stevenson rule[5]. Iodosilane therefore falls into line with $H_3SiCl$ [2] and $H_3SiBr$ [3], in which Si—Cl obeys the rule and Si—Br is slightly shorter than predicted, whereas in the corresponding methyl halides the carbon–halogen bonds are longer than predicted by the rule[6]. The nuclear quadrupole coupling of $^{127}I$ in $H_3SiI$ is only about 64 per cent of that in methyl iodide, which also indicates that the Si—I and C—I bonds here differ in ways similar to those in which the silicon–halogen bonds in $H_3SiCl$ and $H_3SiBr$ differ from the corresponding bonds in the methyl halides[3,4].

More detailed measurements on these spectra, as observed in the 'video' instrument, are in progress, and it is hoped that these will make possible the determination of distortion coefficients for this molecule, and perhaps somewhat more closely determined values of $B_0$ and $eqQ$. It is also expected that the spectra of $H_3{}^{29}SiI$, $H_3{}^{30}SiI$ and deuterated iodosilanes will be observed and make possible a fuller determination of the molecular structure.

The work at the University of Birmingham is part of a programme of microwave spectroscopy in collaboration with the Physics Department of the Telecommunications Research Establishment, Malvern, and grateful acknowledgment is made to the Ministry of Supply for the loan of much of the equipment.

## 'Giant' Fibres in Dragonfly Nymphs

A PRELIMINARY study of transverse and horizontal sections through the ventral nerve cord of late instar nymphs of *Anax imperator* (Anisoptera) has revealed several notable features. Accurate counts of the number of fibres within the commissures have shown that these range continuously from 0 to 16 µ, as set out in the accompanying histogram (Fig. 1). The total number of fibres is approximately the same for the two commissures. Measurements of axon diameters show that some of the larger fibres (12–16 µ) are comparable with the 'giant' fibres of the cockroach[1] and locust[2]. As in the nerves to the stellate ganglia of *Sepia*[3], these fibres form part of a continuous size spectrum and do not appear to differ in nature from the smaller ones. The 'giant' fibres are almost certainly the same as fibres *a*, *b* and *c* described by Zawarzin[4] in his classical studies of *Aeschna* nymphs using a methylene blue technique. The 'giant' fibres pass through all the abdominal

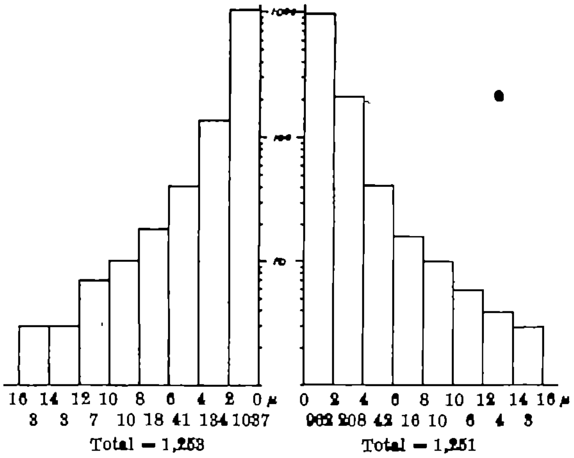

Fig. 1. *Anax.* Histogram to show sizes and frequencies of nerve fibres in the right and left commissures between the 3rd and 4th abdominal ganglia. The number of fibres is plotted on a logarithmic scale

ganglia and send off collaterals into the neuropile of each. Their course through the closely associated metathoracic and first abdominal ganglia to the other thoracic ganglia is more complicated, and has not been fully traced as yet.

Histologically, the 'giant' fibres are of interest because they are surrounded by a definite sheath with well-defined nuclei (Fig. 2). Numerous sheath nuclei have also been observed in sections of the segmental nerves of *Anax*, *Dytiscus* and *Periplaneta*, so that it is probable that at least some insect peripheral nerve fibres are surrounded by such a sheath. In addition to these membranes, there is a distinct sheath (perilemma) enveloping the whole chain of ganglia in these insects (Fig. 2). This sheath is also visible in sections of locust ganglia[4] and it is probably common to all insects. Transverse sections of whole *Periplaneta*, *Dytiscus* and *Calliphora* have clearly shown that the perilemma extends over the peripheral nerves, the neural lamella staining bright blue with Mallory's triple stain. This suggests that the striking tolerance of insect nervous systems to changes in the ionic content[5-7] of the surrounding fluid is partly due to a sheath surrounding the central nervous system in addition to the one which protects the peripheral nerves[8]. The properties of the sheaths around individual axons might similarly be important.

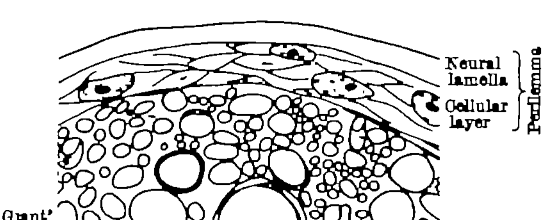

Fig. 2. *Anax.* Part of a transverse section through a commissure shortly after leaving the 3rd abdominal ganglion, showing perilemma and 'giant' fibres with their nucleated sheath. Fixation: 0·2 per cent osmic acid in saturated picric acid. Stain: iron hæmatoxylin. Tracing from a photomicrograph

Electrical activity recorded from electrodes hooked under the abdominal nerve cord includes many different types of action potential, some of which are larger than the others and are presumably from the 'giant' fibres. Mechanical stimulation of the abdomen or anal appendages is followed by bursts of activity in which the large spikes are prominent. Stimulation of the head, however, elicits a different pattern of discharge which does not include the large spikes.

It seems probable that these 'giant' fibres are concerned in the neuromuscular mechanism involved in the rapid expulsion of water from the rectal chamber which brings about jet propulsion in Anisopterid nymphs. The muscles involved are the longitudinal, oblique and dorso-ventral abdominal muscles together with the intrinsic musculature of the hind gut. Water is ejected at a considerable velocity and may reach a height of three feet in air. Simultaneously with the synergic contraction of the abdominal muscles, the legs are drawn into the side of the body and so the resistance to forward movement is decreased. Electrical stimulation (50/sec.) of the abdominal nerve cord in normal and decapitated insects produces this characteristic movement of the legs in addition to active contraction of the abdominal musculature.

No invariable way of evoking swimming has been discovered; but a stream of water is usually expelled when attempts are made gently to grasp the abdomen. The insects must be freely suspended, as swimming is inhibited if the legs are holding pieces of weed, etc. On the other hand, nymphs seized by the head react in a different way. The abdomen is generally flexed laterally and the assailant attacked with the anal appendages, which form a spear-like weapon when closely apposed to one another. These two different responses of the whole animal invite comparison with the two types of electrical discharge recorded from the abdominal nerve cord.

## Endogenous Buds in *Ophioglossum vulgatum* L.

ROOT buds are known in several species of *Ophioglossum* and are the common means of propagation[1-3]. In an experimental investigation of bud formation in *Ophioglossum vulgatum*, root buds have been induced in both entire and decapitated isolated roots. While some buds may be formed from a segment of the root apical meristem, as described by Rostowzew[4], those which occur at random along the root develop from parenchyma cells of the middle cortex and are endogenous. Endogenous buds have also been induced in the pith parenchyma of shoots from which the apex had been excised (Figs. 1–3). In the formation of these endogenous root and shoot buds the following developments have been observed: the inception of a growth centre in a group of deeply seated parenchyma cells; the rapid division of one or more of these cells to form a spherical or ellipsoidal

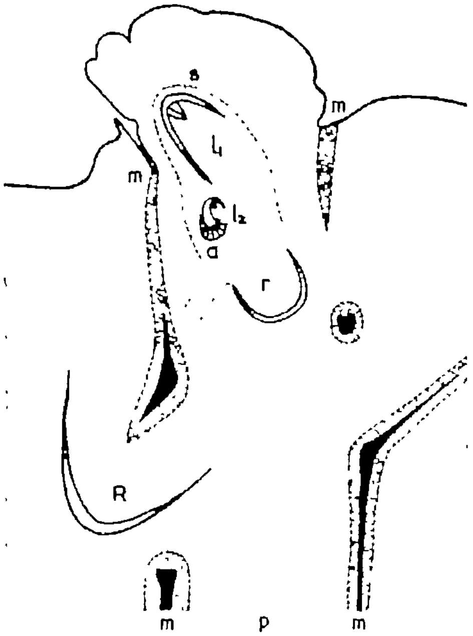

Fig 1. Endogenous bud in the pith at the distal end of a decapitated shoot (Semi-diagrammatic, based on three superimposed camera-lucida drawings). *m*, Meristeles of parent shoot, *p*, pith; *R*, root of parent shoot; *a*, bud apex, $l_1$, $l_2$, leaf primordia, *r*, bud root, *s*, sheath of first leaf, consisting of modified pith parenchyma. (× 40)

meristematic cell mass (Fig. 2); the formation of an upwardly directed nascent shoot apex by the elongation and longitudinal division of a group of cells within this mass (Fig. 3); the lysis and distension of the adjacent cells above, so that the upper surface of the nascent apical meristem becomes freely exposed to the small air space thus formed; the early formation of a rapidly growing first leaf and first root (Fig. 1); a concentric organization of the meristematic and parenchyma cells surrounding the apex so that they constitute a protective sheath which resembles a normal stipular sheath; and the basipetal development of an incipient vascular strand by the longitudinal division of the parenchyma cells situated below the bud (Fig. 1), phloem and xylem being eventually differentiated in this strand. Root buds are not formed by the transformation of incipient lateral roots—these, in fact, do not occur in *O. vulgatum*—and they bear no obligate relationship to the orientation of the root stele. The subsequent developments leading to the formation of a young plant, with a shoot-apex and several leaves and roots, are as in the normal development.

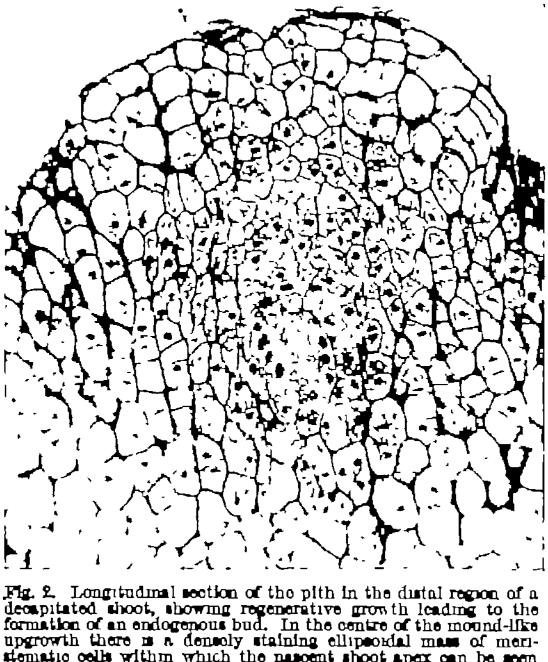

Fig. 2. Longitudinal section of the pith in the distal region of a decapitated shoot, showing regenerative growth leading to the formation of an endogenous bud. In the centre of the mound-like upgrowth there is a densely staining ellipsoidal mass of meristematic cells within which the nascent shoot apex can be seen (*see also* Fig. 3). (× 80.) (*Photo* *Ernest Ashby*)

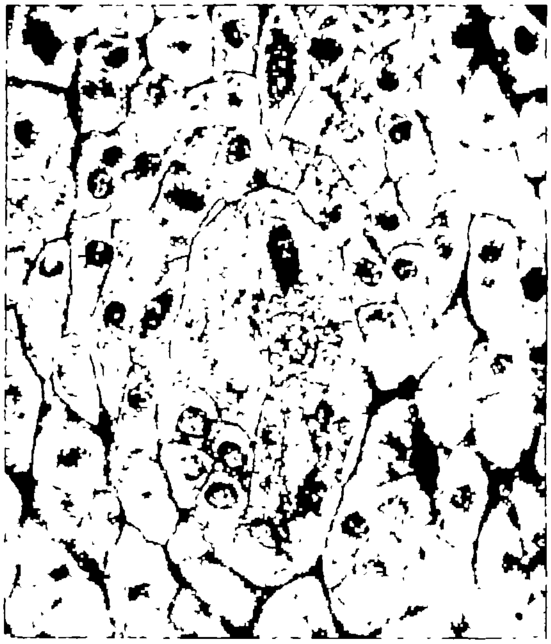

Fig 3. Part of Fig. 2, showing the nascent bud apex. Some of the meristematic cells have elongated and divided by longitudinal walls. The surrounding cells are being thrust outwards and are dividing by walls which are anticlinal to the new apex (× 225) (*Photo*. *Ernest Ashby*)

These developments are very different to those observed in the embryogeny. In the young sporophyte the first distinguishable organs are the foot and the root, the latter being well developed before any apical bud can be discerned; moreover, the first leaf is rudimentary whereas the second is said to take several years before it appears above ground. These differences between bud formation on roots and shoots and the development of the sporophyte on the prothallus illustrate the importance of nutritional factors in morphogenesis. In the inception of buds a nascent shoot apex is the first organ to become apparent and, like other shoot apices, it functions as a self-determining, organizing region, its effects extending into the surrounding parenchymatous tissue within which the endogenous bud is enclosed.

These observations will be described and discussed in greater detail elsewhere.

## Growth of Influenza Virus in the Chick Chorion

HOYLE[1] found that, following inoculation of influenza virus into the allantoic cavity of fertile hens' eggs, complement-fixing 'soluble' antigen became detectable in suspensions of chorio-allantoic membranes before the virus itself. He suggested[1,2] that the 'soluble' antigen was an intracellular form of the virus or a virus precursor. Henle and Henle[3] and Fulton[4], working on similar lines, concluded that 'soluble' antigen and virus antigens appeared together; and Cairns[5] has shown that Hoyle's interpretation of his own results is not necessarily correct, since there are differences in the sensitivity of the experimental methods in this particular situation.

One assumption underlying work of this type is that the cells of the chorio-allantoic membrane respond uniformly to infection by influenza viruses. A test of this assumption has been made by comparing the response to infection of the chorionic surface of the membrane with that of the allantoic. Fertile hens' eggs (10–11 day) were inoculated on the chorionic surface of the 'dropped' membrane[6], or intra-allantoically. The virus used was the *PR*8 strain of influenza *A*; the inoculum was given in 0·5-ml. amounts, diluted in 50 per cent broth-saline. At appropriate intervals after inoculation the allantoic fluids were harvested and the chorio-allantoic membranes removed and stored at – 70° C. until required. Usually, six eggs were tested in each group; all membranes were treated and tested individually. They were frozen rapidly and thawed slowly three times, spun lightly and the supernatant fluids (membrane suspension) removed. The allantoic fluids were titrated for hæmagglutinin and the membrane suspensions titrated for infectivity in eggs, complement-fixing 'soluble' antigen and hæmagglutinin (following treatment with sufficient receptor-destroying enzyme[7] to remove all inhibitor present). The variables in these experiments were the route of inoculation—chorionic or intra-allantoic—the size of inoculum and the time of incubation.

Following intra-allantoic inoculation, hæmagglutinin appeared in the allantoic fluid in high titre, and membrane suspensions showed high titres of infective virus, 'soluble' antigen and hæmagglutinin. The results with different sizes of inoculum and different times of incubation followed the pattern expected from the work of Henle and Henle[3] and von Magnus[8]. By contrast, the behaviour of eggs injected by the chorionic route was strikingly different. In general, no agglutinating virus was detected in the allantoic fluid, even following inoculation of $10^{3}$–$10^{6}$ $ID_{50}$ of virus. This statement needs qualification, since in early experiments a proportion of eggs (14/44) showed high titres of agglutinin in the allantoic fluid. It was suspected that these anomalies may have resulted from minor injuries to the membrane during 'dropping', and in later experiments membranes were 'dropped' 24 hr. before chorionic inoculation of virus in order to allow for healing of small lesions. This change in technique was rewarded by a sharp drop in the number (7/104) of eggs showing agglutinin in the allantoic fluid. Since the latter behaved in all respects like eggs injected intra-allantoically, they will be excluded from the description which follows.

Membrane suspensions from eggs inoculated chorionically showed low infectivity titres following injection of 100 $ID_{50}$ of virus. The titres showed only a slight rise (10 to 100-fold) in infectivity over the amount of virus inoculated and were much lower ($10^{-4}$ to $10^{-5}$-fold) than those of membranes from corresponding eggs inoculated intra-allantoically. Agglutinin and 'soluble' antigen were not detected. With large inocula (approximately $10^{6}$ $ID_{50}$ of virus) traces of agglutinin were detected, but only following treatment of the suspensions with receptor-destroying enzyme. However, high titres of 'soluble' antigen were found. The titre of 'soluble' antigen in membrane suspensions was roughly proportional to the amount of virus inoculated, although there was considerable variation in the titre of individual eggs given the same inoculum.

In those eggs in which it was measurable, agglutinin was first detected four hours after chorionic inoculation of $10^{6}$–$10^{6.5}$ $ID_{50}$ of virus; it was still detectable up to 24 hr. but not at 48 or 72 hr. Complement-fixing antigen was first detected at 3 hr. in 6/12 eggs after inoculation of the same amount of virus. This proportion is higher than that of allantoically inoculated eggs, where complement-fixing antigen was detected in only 1/12 eggs at 3 hr.; however, the difference is barely significant ($p < 0{\cdot}10 > 0{\cdot}05$). In eggs inoculated by the chorionic route, the 'soluble' antigen titre rose to reach a maximum at 24 hr. and had declined considerably by 72 hr. Since eggs injected by the chorionic route behaved in some respects as if they supported only a single 'cycle' of virus multiplication, it was interesting to note that the decline in 'soluble' antigen titre could be prevented by repeated chorionic inoculations of virus.

The possibility was considered that the different behaviour of chorionic and allantoic cells might depend on the different physiological conditions in the two layers. Experiments were therefore carried out with chorio-allantoic membrane *in vitro*, using the principles of a technique previously described[9] and now modified to allow infection of one layer at a time only. Infection of chorionic and allantoic layers separately was carried out with the *BAR* (*A'*) strain. 16/18 pieces of membranes infected on the allantoic surface showed high-titred agglutinin in the supernatant fluid; only 1/18 pieces infected on the chorionic surface showed agglutinin, and on inspection an obvious tear was found in the single positive piece. These results support those obtained by egg techniques, and confirm the essential difference in response to infection of chorionic and allantoic cells.

## Tuesday, January 13

Institution of Chemical Engineers (in the Great Hall, Caxton Hall, Caxton Street, London, S.W.1), at 2 p.m.—Symposium on "Bursting Discs".

University of London (at the Royal Veterinary College and Hospital, Camden Town, London, N.W.1), at 4 p.m.—Prof. S. A. Asdell (Cornell University): "Mammalian Reproduction".* (Further Lectures on January 14 and 15.)

Institution of the Rubber Industry (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Lecture on "Calendering"; at 7 p.m.—Dr. R. G. James: "Some Aspects of Latex Thread Coagulation"; Dr. H. J. Stern: "Latex for Surface Coatings".

University of London (at the Senate House, Malet Street, London, W.C.1), at 5.30 p.m.—Sir James Scott Watson: "Soil and Food" (Sanderson-Wells Lecture).*

## Wednesday, January 14

Society for Applied Bacteriology (joint meeting with the Microbiology Group of the Society of Chemical Industry, at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 10.15 a.m.—Scientific Papers; at 2.15 p.m.—Symposium on "Recent Advances in Microbiological Methods".

Royal Sanitary Institute (at 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Discussion on "Fluorides in Water Supplies" (to be opened by Dr. Roy C. Hoather).

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. W. H. P. Johnson: "Use and Abuse of Fuels".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Physical Society, Acoustics Group (in the Physics Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 5.15 p.m.—Dr. K. Tamm and Dr. G. Kurtze: "Sound Absorption in Aqueous Solutions of Electrolytes—(a) Measuring Techniques, (b) Results and Explanation".

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. H. C. Rampton: "Methods of Hydrocarbon Type Analysis".*

Royal Statistical Society, Study Section (at the R.I.M.A. Theatre, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Mr. D. L. Lamberth: "Forms with Many Functions".

## Thursday, January 15

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. P. H. R. James: "Recent Experiments in the Psychology of Vision".*

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Society of Chemical Industry, Road and Building Materials Group (at the Building Centre, Store Street, London, W.C.1), at 6 p.m.—Mr. A. R. Smee and Mr. L. Mullins: "The Use of Rubber in Bituminous Road Surfaces".

British Institute of Radiology (at 32 Welbeck Street, London, W.1).—Discussion on "The Technical Problems affecting Radiology".

## Friday, January 16

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. L. S. le Page and Mr. A. L. P. Milwright: "Radar and Ice".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. H. N. Pemberton: "Welding in Marine Engineering" (Thomas Lowe Gray Lecture).

## Friday, January 16—Saturday, January 17

Institute of Physics, Industrial Radiology Group (joint meeting with the Hospital Physicists' Association, at the Royal Institution, 21 Albemarle Street, London, W.1).—Discussion on "Radiation Protection".

Friday, January 16

At 7 p.m.—"Medical and Industrial Aspects".

Saturday, January 17

At 9.30 p.m.—"Monitoring".

## Saturday, January 17

Biochemical Society (in the Department of Physiology and Biochemistry, King's College, Strand, London, W.C.2), at 10.30 a.m.—Scientific Papers.

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

University Graduate with first- or second-class honours in pure or applied science for the Department of Pedology, Soil Survey (Scotland) Section—The Secretary, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (January 17).

Physicist at the Central Research Establishment, Worton Hall, Isleworth, to lead a small team engaged in research on the structure of solids and on the mechanism of brittle fracture and abrasive wear—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, endorsed TT/576 (January 19).

Keeper in the Department of Natural History, City Museum and Art Gallery, Birmingham 3—The Director (January 26).

Lecturer (honours graduate) in Inorganic and Physical Chemistry—The Principal, Heriot-Watt College, Edinburgh (January 26).

Chemist and Bacteriologist—The Clerk to the Bucks Water Board, 7 Temple Square, Aylesbury, Bucks (January 30).

Chair of Fuel Technology—The Registrar, The University, Sheffield (January 31).

Senior Research Officer or Research Officer (with university degree with honours in agriculture or science and experience in research in plant nutrition) for investigations into plant nutrition and biological problems, with particular reference to the cultivation of fruit trees, including citrus, in the Murrumbidgee Irrigation Area (Ref. 3940), and a Senior Research Officer or Research Officer (Chemist) (with university honours degree in science or equivalent qualification) to conduct research into various chemical aspects of plant growth and soil problems on the Murrumbidgee Irrigation Area (Ref. 3941)—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (January 31).

Lecturers (2) in Botany, and a Lecturer in Organic Chemistry—The Secretary, Queen's University, Belfast (February 25).

Senior and Junior Fellowships for fundamental research in aerodynamics or aeronautical structures—The Director, Royal Aircraft Establishment, Farnborough, Hants (March 1).

Broodbank Fellowship for research in biochemistry or biophysics, with special reference to the principles and practice of food preservation—The Registrary and the University Registry, The Old Schools, Cambridge (March 31).

Will Edmonds Fellowship for clinical research in hospitals in the Metropolitan area of London—The Assistant Secretary, Royal College of Physicians, Pall Mall East, London, S.W.1 (March 31).

Chemist or Chemical Engineer at Salwick, near Preston, to lead a team on pilot plant experimental work, and for interpreting fundamental scientific information and providing design data—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting 409.

Senior Chemist (Senior Scientific Officer grade) for research laboratories at Salwick, near Preston—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting 400.

Experimental Officer at Torry Research Station, Aberdeen, for research into the physics of fish preservation, involving investigations of properties of smoke, measurement of moisture, high vacuum techniques, colorimetry, and servo-control methods—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.116/52A.

Scientific Assistant (with a degree in agriculture or natural science, a knowledge of French and German, and the ability to write clear, concise abstracts in English) for examining and abstracting world scientific literature on grassland and field crop research—The Director, Commonwealth Bureau of Pastures and Field Crops, Aberystwyth.

Scientific Officer (with first- or second-class honours degree or equivalent in chemistry) with sound knowledge of electrochemistry and electrodeposition of metals, at the Ministry of Supply Establishment, Aldermaston—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.317/52A.

# REPORTS and other PUBLICATIONS

(*not included in the monthly Books Supplement*)

## Great Britain and Ireland

Association of Universities of the British Commonwealth. United Kingdom Postgraduate Awards (Fellowships, Scholarships, Grants, etc.), 1952–53. Pp. 94. (London: Association of Universities of the British Commonwealth, 1952.) [1211

Annual Report of the British Interplanetary Society. Pp. 301–364. (London: British Interplanetary Society, 1952.) [1811

Question: a Journal. Edited by H. Westmann. Vol. 5, No. 1: Conflicts of Loyalties. By Prof. M. Polanyi, J. H. Oldham, Prof. W. R. Niblett, H. Westmann and Herbert Read. (Published for the Present Question Conference, Ltd.) Pp. 112. (London: Hammond, Hammond and Co., Ltd., 1952.) 3s. 6d. [1811

Department of Scientific and Industrial Research. Report of the Hydraulics Research Board for the Years 1947–1951 with the Report of the Director of Hydraulics Research for the Years 1948–1951. Pp. iv+40+12 plates. (London: H.M. Stationery Office, 1952.) 3s. net. [1811

Department of Agriculture: Fisheries Branch. Report on the Sea and Inland Fisheries for the Year 1951, incorporating Statistics of the Capture of Salmon, Sea Trout and Eels. (Pr. 1344.) Pp. 47. (Dublin: Stationery Office, 1952.) 2s. 6d. [1911

British Hat and Allied Feltmakers Research Association. Fifth Annual Report of the Director of Research for Year ending August 1952. Pp. 20. (Manchester: British Hat and Allied Feltmakers Research Association, 1952.) [2011

Department of Scientific and Industrial Research. Report of the Mechanical Engineering Research Board with the Report of the Director of Mechanical Engineering Research for the Year 1951. Pp. iv+88+4 plates. (London: H.M. Stationery Office, 1952.) 2s. net. [2011

Select List of Standard British Scientific and Technical Books. Edited by H. R. McColvin. Compiled at the request of the British Council. Fourth edition revised and enlarged. Pp. 72. (London: Aslib, 1952.) 7s. 6d.; to members of Aslib, 6s. [2011

Report from the Select Committee on Nationalised Industries together with the Proceedings of the Committee. Pp. xxiv. (London: H.M. Stationery Office, 1952.) 9d. net. [2411

National Physical Laboratory. Notes on Applied Science, No. 2: The Industrial Application of Aerodynamic Techniques. Pp. vi+37. (London: H.M. Stationery Office, 1952.) 3s. 6d. net. [2011

Angry Prayers: a Report on the Convention of British Animal Protection Societies. Edited by Keidrych Rhys. Second edition. Pp. viii+64. (London: National Canine Defence League, 1952.) 2s. 6d. net. [2611

City of Leeds. Annual Report of the Sub-Libraries and Arts (Museums) Committee to the Council for the Year ended 31st March, 1952. Pp. 10. (Leeds: City Library, 1952.) [2611

Ultrasonic Examination of Axles of Railway Rolling Stock. By Dr. Erich Martin. (Report No. 776 of the Committee on Materials of the Verein Deutscher Eisenhuttenleute.) Translated. Pp. 24. (London: Solus-Schall, Ltd., 1952.) [2611

## Other Countries

New Zealand Department of Scientific and Industrial Research. Geophysical Memoir 1: Magnetic Resurvey of New Zealand at Epoch 1st July 1945. By H. F. Baird and A. L. Cullington. Pp. 54. (Wellington: Government Printer, 1952.) [1111

Cawthron Institute. Annual Report, 1951–52. Pp. 42. (Nelson, N.Z.: Cawthron Institute, 1952.) [1111

United States Department of Commerce: National Bureau of Standards. Applied Mathematics Series 25: Tables of the Bessel Functions $Y_0(x)$, $Y_1(x)$, $K_0(x)$, $K_1(x)$, $0 \leq x \leq 1$. Pp. ix+60. (Washington, D.C.: Government Printing Office, 1952.) 40 cents. [1111

Annals of the New York Academy of Sciences. Vol. 55, Article 2: The Chick Embryo in Biological Research. By David A. Karnofsky and 27 other authors. Pp. 37–344. 4 dollars. Vol. 55, Article 3: Shock Syndrome. By John Scudder and 25 other authors. Pp. 345–542. 3.75 dollars. (New York: New York Academy of Sciences, 1952.) [1111

Government of India: Meteorological Department. Report on the Administration of the Meteorological Department of the Government of India in 1950–51. Pp. ii+46. (New Delhi: Meteorological Department, 1952.) [1211

Proceedings of the Eighth Meeting of the Crops and Soils Wing of the Board of Agriculture and Animal Husbandry in India, held at Patiala from 28th to the 31st March, 1950. Pp. iii+307. (Delhi: Manager of Publications, 1952.) 12 rupees; 19s. [1211

Proceedings of the Eighth Meeting of the Animal Husbandry Wing of the Board of Agriculture and Animal Husbandry in India, Mysore, 17th to 22nd February, 1949. Pp. xii+260. (Delhi: Manager of Publications, 1951.) 11.14 rupees; 18s. 6d. [1211

Indian Forest Bulletin (New Series). No. 101 (Cellulose and Paper): Indigenous Cellulosic Raw Materials for the Production of Pulp, Paper and Board, Part 11, Chemical Pulps from *Andropogon contortus*, Linn. (*Kusal* grass.) By R. V. Bhat and M. G. Karnik. Pp. ii+8. (Delhi: Manager of Publications, 1952.) 10 annas; 1s. [1311

Indian Forest Records (New Series). Vol. 1, No. 1 (Composite Wood): Weathering Trials on some Synthetic Resin Bonded Aircraft Components. By D. Narayanamurti, Joseph George, N. Subramanyan and N. R. Das. Pp. 8+10 plates. (Delhi: Manager of Publications, 1952.) 12 annas; 1s. [1311

Indian Forest Leaflet. No. 130 (Silviculture): General Formulae for Measurement of Heights of Trees. By V. S. Krishnaswamy. Pp. 9. (Delhi: Manager of Publications, 1952.) 10 annas; 1s. [1311

Chemical Apparatus in the U.S.A. Technical Assistance Mission No. 23. Report by a Group of European Experts. Pp. 224. (Paris: Organisation for European Economic Co-operation; London: H.M. Stationery Office, 1952.) 20s. net. [1811

Koninklijk Nederlands Meteorologisch Instituut. No. 102 (Mededelingen en Verhandelingen Serie A, 57): Klimaat en Brouwgersteteelt in Nederland; een Bijdrage tot de Oecologie van de Zomergerst. Door Dr. C. Kramer, Dr. J. J. Post en W. Wilten. Pp. 149. 2.25 f. No. 106a: Upper Air Data, 34, 1949. Pp. 90. 12 f. No. 108: Seismic Records at De Bilt, 35, 1947. Pp. vii+30. 1 f. ('s-Gravenhage: Staatsdrukkerij- en Uitgeverijbedrijf, 1951–1952.) [1811

Commonwealth Scientific and Industrial Research Organization. Bulletin No. 269: A Comparative Study of *Pisum*, *Vicia*, *Lathyrus* and *Lupinus* Varieties grown in Buckingham Sand in the Coonalpyn Downs, South Australia. By D. S. Riceman and J. K. Powrie. Pp. 36+3 plates. (Melbourne: Commonwealth Scientific and Industrial Research Organization, 1952.) [1811

Publications de l'Institut National pour l'Étude Agronomique du Congo Belge. Hors Série, 1952. Pp. 436. (Bruxelles: Institut National pour l'Étude Agronomique du Congo Belge, 1952.) 160 francs. [1811

Coryndon Memorial Museum. Occasional Papers, No. 3: Notes on African Gomphidae, by Lieut.-Colonel F. C. Fraser, and Three New Species of Odonata, by E. C. G. Pinhey. Pp. 16. (Nairobi: Coryndon Memorial Museum; Cambridge: Deighton, Bell and Co., 1952.) 5s. [1811

Goteborgs Kungl. Vetenskaps- och Vitterhets-Samhalle. Reports of the Swedish Deep-Sea Expedition, 1947–1948. Vol. 5: Sediment Cores from the East Pacific. By Gustaf Arrhenius. Fasc. 1. Pp. 227. 75 kr. Vol. 5, Part 2: Description of the Sediment Cores. By Gustaf Arrhenius. Appendix: Description of Plates. Pp. 4+plates 2.6.1–2.62. (Goteborg: Elanders Boktryckeri A.B., 1952.) [1911

Unesco: International Bureau of Education. Publication No. 139: XVth International Conference on Public Education, convened by Unesco and the I.B.E., Geneva, 1952. Teaching of Natural Science in Secondary Schools. Pp. 216. (Paris: Unesco; Geneva: International Bureau of Education; London: H.M. Stationery Office, 1952.) 5 francs; 8s. 6d. [1911

Scientific Council for Africa South of the Sahara. First Report, November 1950 to June 1952. Pp. 48. (Kikuyu: Scientific Council for Africa South of the Sahara, 1952.) 2s. 6d. [2011

Bulletin of the American Museum of Natural History. Vol. 99, Article 8: The Neotropical Genera *Procornitermes* and *Cornitermes* (Isoptera, Termitidae.) By Alfred E. Emerson. Pp. 475–540. (New York: American Museum of Natural History, 1952.) 80 cents. [2011

University of California Publications in Zoology. Vol. 52, No. 1: Distribution and Variation of the Brown Towhees. By John Davis. Pp. 120. 1.25 dollars. Vol. 52, No. 2: A Comparison of Variation, Behavior and Evolution in the Sea Bird Genera *Uria* and *Cepphus*. By Robert W. Storer. Pp. 121–222+2 plates. 1.25 dollars. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1951–1952.) [2611

Report of the International Scientific Commission for the Investigation of the Facts concerning Bacterial Warfare in Korea and China. Pp. 665. (Prague: World Council of Peace, 1952.) [2611

Colony and Protectorate of Kenya. Report of the Forest Department for the Years 1948, 1949, 1950. Pp. 62. (Nairobi: Government Printer, 1952.) 3s. [2611

Transactions of the American Philosophical Society. New Series, Vol. 42, Part 3: Three Revolutionary Architects, Boullée, Ledoux and Lequeu. By Emil Kaufmann. Pp. 429–564. (Philadelphia: American Philosophical Society, 1952.) 2 dollars. [2611

Beach Erosion Board: Corps of Engineers. Technical Memorandum No. 28: Source of Beach Sand at Santa Barbara, California, as indicated by Mineral Grain Studies. By Parker D. Trask. Pp. ii+24. (Washington, D.C.: Government Printing Office, 1952.) [2611

Report on Federal Forest Administration in the Federation of Malaya for the Year 1951. By J. P. Edwards. Pp. 67+4 plates. (Kuala Lumpur: Government Printer, 1952.) 2 dollars; 4s. 8d. [2611

Bulletin of the American Museum of Natural History. Vol. 99, Article 9: A New Fossil Tortoise from Mona Island, West Indies, and a Tentative Arrangement of the Tortoises of the World. By Ernest Williams. Pp. 541–560+plates 44–47. 50 cents. Vol. 99, Article 10: A Pseudosuchian Reptile from Arizona. By Edwin H. Colbert. Pp. 561–592+plates 48–49. 50 cents. (New York: American Museum of Natural History, 1952.) [2611

American Journal of Science. Bowen Volume. (Geophysical Laboratory, Carnegie Institution of Washington, Publication No. 1200.) Part 1. Pp. viii+318. Part 2. Pp. iv+319–627. (New Haven, Conn.: American Journal of Science, 1952.) [2611

Skrifter udgivne af Kommissionen for Danmarks Fiskeri- og Havundersøgelser. Nr. 14: Kommissionen for Danmarks Fiskeri- og Havundersøgelser, 1902–1952. Af Erik M. Poulsen. Pp. 78. (København: C. A. Reitzels Forlag, 1952.) 6 kr. [2011

Meddelelser fra Danmarks Fiskeri- og Havundersøgelser. Ny Serie, Bind 1, Nr. 1: Undersøgelse af Industrifisk-Fiskeriet i Danmark, Saerlig I, 1949–51. Af Aage J. C. Jensen. Pp. 81. 15 kr. Serie Plankton, Bind 5, Nr. 5: Investigations on the Phytoplankton in the Southern North Sea in May 1947. By Jul. Grøntved. Pp. 50+1 plate. 10 kr. (København: C. A. Reitzels Forlag, 1952.) [2611

State of California: Department of Fish and Game, Bureau of Game Conservation. Game Bulletin No. 6: A Survey of California Deer Herds, their Ranges and Management Problems. By William M. Longhurst, A. Starker Leopold and Raymond D. Dasmann. Pp. 136. (San Francisco: Department of Fish and Game, 1952.) [2011

# PROFESSIONAL STANDARDS IN THE WELFARE STATE

A LIVELY chapter in Mr. R. Lewis and Mr. A. Maude's survey "The English Middle Classes", three years ago, discussed the position and problems of the professions in the society of to-day. That discussion has now been expanded into a full-length study*, written with the same charm as well as scholarship, and pervaded with wit, sometimes a little tinged with malice. It covers a wider field than the earlier book by Carr-Saunders and Wilson, to which it is a natural complement, glancing at the Church and the Armed Services, which they excluded. The detailed historical account which occupies the bulk of that book is the natural starting point for this new survey, which reviews and analyses the trends of the past two decades with a lucidity and vivacity that should commend it far outside the range of the widest definition of the professional classes to whom it, presumably, is primarily addressed.

To professional organizations, indeed, it offers a clear challenge; it sounds a ringing call to the humblest members of a profession to face the implications and responsibilities of a situation in which their position threatens to continue to deteriorate. No less it is a challenge to thought, and to action, on the part of all who are concerned about the effectiveness of our social, and indeed our industrial organizations, from a national as well as from a personal or professional point of view. The authors have the courage to ask questions that have hitherto been evaded; and the issues confronting us in shaping educational policy and social services, especially the national health services, are described frankly and realistically. Criticism is constructive as well as penetrating. The professional man, be he scientist or technologist or otherwise, is summoned to work much harder to strengthen an influence already waning, and, accepting the responsibilities and implications of what Mr. Lewis and Mr. Maude describe as an aristocracy of talent, to seek, personally and through his professional associations, to protect himself and defend his ideals.

Mr. Lewis and Mr. Maude unhesitatingly defend the professional ideal. They are convinced that it has an essential place in the world to-day, and that, in fact, the institutions of democracy and of social service cannot function unless the traditions and standards of professional men are respected and upheld. But they are equally clear as to the price that has to be paid; and loose claims to be regarded as a profession are analysed and rejected with a ruthlessness verging at times on contempt. The validity of the claim thus trenchantly analysed of some of the newer specialisms to be regarded as professions, leading to the consideration of the question of what is a profession, is one of the three major issues raised in the book. The second is that which arises through the increasing extent to which the State has become the client of the professional man. The implications of this position, the impact of nationalization and the position of what are termed the socialized professions—in Britain, medicine and dentistry, with the other auxiliaries of the National Health Service, such as opticians, pharmacists and nurses, and teaching and law—are reviewed in three successive chapters. The third issue is that of professional education. This is considered in close relation to the other problems and to the factors which may determine supply and demand for practitioners.

---

* Professional People. By Roy Lewis and Angus Maude. Pp. viii+284. (London: Phoenix House, Ltd., 1952.) 18s. net.

On the first question, Mr. Lewis and Mr. Maude reach no hard-and-fast definition of what constitutes a profession. They incline to accept that of the "Oxford English Dictionary" which Carr-Saunders and Wilson quoted with approval: "a vocation in which a professed knowledge of some department of learning or science is used in its application to the affairs of others or in the practice of an art founded upon it". Unlike Carr-Saunders and Wilson, they reject very firmly the claims of management or administration to be considered as a profession. Equally they question the conclusion that the control of business or industry is likely to pass into the hands of those marked by professional outlook. The business instinct, they remark, will remain indispensable, and the extent to which it is influenced by the professional ideal will depend on the extent to which management passes into the hands of those who also, whether as lawyers, scientists or technologists, accept loyalty to some professional tradition

Nevertheless, the authors insist on the value to-day of the professional outlook or spirit, marked at least by some measure of personal integrity on the part of the practitioner and some relationship of trust between practitioner and client or employer. The vital issue to-day is the extent to which professional people can remain professional in this sense, in the face, on one hand, of what is essentially dilution and, on the other, of the increase of professional employment by the State. It is the free, rather than the controlled, professions which set the standard and justify professional prestige. "The moment that the state organises, trains, and employs all the members of a profession, we can no longer speak of it as a profession. We can only speak of a body of expert officials. Such officials might, or might not, have high standards of conduct—but those standards would depend on the state of society, not the professional spirit; and any freedom they enjoyed would be on sufferance from those who held power."

This was foreseen by Carr-Saunders and Wilson. In such circumstances the professional man can no longer find in his vocational organizations the permanent anchorage and shelter regarded as the prerequisite for independent professional service to society. We are thus led to the second main issue raised in this book. Here the picture painted of the frustrating and depressing effect of State service and nationalization on the professional spirit is profoundly disturbing. Sometimes the deterioration of standards is for the time being obscured or mitigated, as in the National Health Service, by the possibility of living on the tradition of the past. When that is no longer possible, Mr. Lewis and Mr. Maude clearly do not believe that the traditional professional attitudes and standards can be maintained.

The third, and related, problem is that of professional education. The State, Mr. Lewis and Mr. Maude point out, is in a hurry to get more and more experts: simultaneously it seeks to encourage them to get a better training, and to reduce the period of training to get qualified men from anywhere, anyhow; at the same time it is trying to curb rising costs. Bluntly and specifically they write (of the nursing profession): "The root cause of the trouble is, quite simply, that (unless all other professions and jobs for girls are to be further raided for recruits) there are not enough young women of adequate intelligence and education in the country to staff both the schools and the hospitals, at the present level of services provided, without lowering standards".

It is idle at this stage to indict those who, introducing the new national services, failed to heed the scriptural advice first to count their resources, nor do Mr. Lewis and Mr. Maude allow themselves to stray from the point. They emphasize the way in which professional education itself depends on the quality of primary and secondary education, and thus on our ability to maintain the standards of teaching at that level. They indicate some of the implications of the situation for the professional institutions and the universities, and there is forthright criticism of some professions, notably of the excessive specialization of engineering. They insist that the solution of the present problem of professional education depends, above all, on genuine interest and sacrifice on the part of the best and most highly paid members of the engineering and scientific professions. They must teach; and at the same time, throughout the field of professional training, teachers must be helped and encouraged to vary their employment between practical work and teaching.

This brief chapter on professional education has some biting remarks on professional organizations, particularly in regard to technological education; and it places the responsibility for the dangers into which professional education is drifting—both over-specialization and inadequacies in the supply of the right type of talent and character—fairly on professional people themselves, as members of learned institutions and universities. Personal sacrifice as well as clear thinking will be required, and the authors add that professional people will never solve these problems by sitting on government committees, for even to accept membership of one of these is to deny ultimate responsibility for action.

That the State is setting the professions tasks beyond their powers is the real danger; but it does not follow that those demands inevitably involve dilution and the lowering of standards. The demands are not likely to be checked merely in the interests of the professions; nevertheless, this book gives some convincing reasons why it is in the general interest to diminish the present strain on the Civil Service and certain professions, even at the cost of postponing further nationalization measures or developments in social welfare until resources are more commensurate with requirements. The lowering of standards can be avoided if professional bodies will devise clear definitions of professional ideals and standards, and limit the maintenance of high standards to situations in which the nature of the work makes it really necessary.

We are not left in doubt as to what such a policy demands of professional institutions. Institutional 'stiffneckedness' alone, the authors remark, will not preserve the professional tradition; and even in teaching it may be possible to utilize the auxiliary 'technician' once the opposition to salary differentials for graduates is discarded—an opposition to which is attributed largely the decline in academic standards in grammar schools. To distinguish between technician and technologist, between strictly professional work and non-professional, whether administrative or of the ancillary technical type which can be done by a laboratory assistant or other trained technician, requires clear thinking. Such decisions must be taken by the professional institutions and none other, and they must equally take account of the legitimate aspirations of the technicians, providing means and opportunity for those who have the ability to qualify for the professional grade. It means ruthlessness, as well as a clear conception of the nature of a profession, in dealing with some of the newer claimants to that title; and, quite possibly, a good deal more flexibility, as well as internal reform, in some existing professions.

"Only the doctors themselves," remark Mr. Lewis and Mr. Maude, "can preserve the integrity of their own profession"; and fundamentally the maintenance of standards is thus linked with the question of the proper use of the professional man or expert. This further reminder to the administrator and legislator that the supply of brains and ability in Britain is strictly limited, and that much of it is at present being wasted on work that could be done by less-qualified people, is also a challenge to the professional institutions to give adequate thought to the means of eliminating such waste and to the implications of the growth of modern administration for their own members. It is a stern warning of what may follow if professional institutions, on the other hand, disregard such constructive work and responsibilities, and become preoccupied exclusively with their protective or purely economic functions.

These economic functions are not ignored in this book. On the contrary, full weight is given to the difficulties which the deterioration in the economic position of the professions place in the way of recruitment of men and women of the requisite ability. The primary problem is none the less that of maintaining standards where the nature of the work demands high professional standards, and that in itself plays its part in attracting men and women of the ability and character required. Paraphrasing a passage from a recent Croonian Lecture by Dr. T. F. Fox, which they quote with approval, Mr. Lewis and Mr. Maude maintain that a professional man is a practitioner first and an employee second and incidentally.

A main argument of this book is that the basis of professional life is the contract between practitioner and client—an essentially ethical relationship—and that this fiduciary and confidential relationship lies not merely at the heart of the great professions of medicine and law, and their derivatives, but also, by the power of example and co-practice in the same environment, at the heart of all professions. The body of private practitioners and consultants sets the tune for professional life; in the last resort, the devotion which characterizes the Civil servant and which might be regarded as the ethic appropriate to an age of 'socialized' professions and nationalized industries, is also very largely derived from the conduct of the free professions. Reasonably enough, the authors suggest that service and selflessness are founded ultimately more on direct personal relations—ties of honesty, trust, honour and loyalty—between a professional man and his client, as they have been practised over generations, than upon any natural or instinctive urge in man to serve the community under irksome restraints, with a load of responsibility and for limited rewards.

To preserve this personal responsibility to the client in the professions of law and medicine is regarded by Mr. Lewis and Mr. Maude as the primary task, and it has to be achieved within the framework of partly 'socialized' administration and finance. They insist, too, that financial freedom must go with professional freedom, and that the professions, like the universities, should so far as possible be free from Treasury dominance. Linked with this is the question of administration, particularly as presented by the dangers which the growth of centralized organizations offers to the survival of professional traditions. Here they comment briefly on the question of leadership from a novel angle; and a remark as to the possibility of administration becoming the happy hunting ground of the second-rate mind is a shrewd hit at some current discussions and theories.

Through this book blows a refreshing air of common sense. Its realism is inspiring and persuasive. It deals some shrewd blows, and may provoke some irritation, even anger. But the professions have been warned, and also shown that they have some effective replies if they have the courage to take the right action. They could, for example, well afford to ignore the charge that by upholding educational standards they are failing to provide the experts in the numbers required by the nation: they would do better to refute the charge by emphasizing the effect on quality, or by pointing to the present prodigious waste of professional talent in government departments and in nationalized industry. "Those who claim to possess something of vital importance to the community should be prepared, not only to state clearly what it is, but also to fight to preserve it for the community's good."

That challenge must be met by professional people with vision as well as energy and courage. The book under discussion indicates also some of the steps that could be taken by professional people to adapt their institutions, both for the preservation of professional traditions and standards and for the more effective discharge of their professional functions and responsibilities to their clients, and to the society in which both client and profession have a vital part to play.

# HISTORY OF GEOLOGY IN GREAT BRITAIN

Geological Survey of Great Britain
By Sir Edward Bailey. Pp. xii+278+4 plates. (London: Thomas Murby and Co., 1952.) 22s. 6d. net.

THIS account of the history of the Geological Survey of Great Britain, written by a former director of the Survey, is a noteworthy publication. Although it follows a centenary volume by one of his predecessors published still far short of twenty years ago, it will not surprise those who have known both authors that the two books differ in many respects. The present volume is one that should find a place in every geological library, and it is worthy to be added to books devoted to the history of the subject.

The Geological Survey is the oldest organization of its kind in the world, dating its institution from 1835; there was, of course, official but discontinuous geological mapping before that date in Great Britain and elsewhere. The Survey has been taken as a pattern for the organization of similar work by many countries. This book contains an account of the problems met with through this long history, and of the ways in which they have been dealt with. Each chapter (though they are not called by that name) deals with the work of one of the successive directors and with his more important achievements and difficulties. Alongside this history of Survey activities, there is some account, especially in the earlier years, of the development of geological ideas both in the Survey and outside. To the student this volume will thus supply a valuable introduction to the history of the science as a whole. As the Geological Survey grew, there was a considerable degree of similarity between the development of ideas among its members and of those who were not attached to its staff. The numbers of those geologists engaged in the Survey and in the universities have always been small—smaller than those in most sciences—and, leaving aside the very important band of amateurs whose contribution to some fields of geology have been outstanding, the Survey has held on an average about one-half of the employed geologists in Britain. It is not surprising, therefore, to find that in many ways its history is to a great extent the history of British geology.

The Geological Survey was founded in order to expedite the provision of one-inch maps with geological boundaries, and the production of such maps (each with an accompanying memoir containing a description of the geology of the area which is summarized on the map) has continued to be one of the Survey's most important tasks. Several diagrams show very clearly the progress towards this objective. But with greater demands the work became slowed down very considerably, even so long as seventy or eighty years ago. Thus the reader is shown on p. 84 how the rate of completion of English one-inch maps became less than half as rapid under Ramsay as it had been in a corresponding period under his predecessor Murchison. The rate rose again with the next director, Archibald Geikie, to exceed that reached under Murchison. This variation is partly accounted for by the use made of six-inch maps as a basis of surveying. This was officially ended by Geikie in the 'eighties, though it had been in existence for some twenty years.

Geikie was anxious to complete the geological mapping of Great Britain, having more or less undertaken on his appointment "to wind up most of the activities of his office". How many since that time have demanded to know how long it would be before the primary task of the Survey was accomplished? All one can now say, unless there is a large expansion in numbers, with the demand for greater detail and for the need for frequent revision (at least in some areas), is that the geological survey will never be complete, for new tasks are added more rapidly than they can be overtaken. Geikie would find an organization much larger than in his day, but with its responsibilities continually expanding.

So many topics are discussed in this volume, especially in those sections relating to later years, that a reviewer can only indicate the wide range of problems. The linkage with other government services is traced from the days when the Geological Survey was one of the very few scientific bodies established under the Government (many may read with amazement that in 1871 a director's funeral was joined by royal carriages and that a Prime Minister followed the bier), to its present position as one of the divisions since 1919 of the Department of Scientific and Industrial Research. The glimpse of the Geological Survey's relation to water-divining, or dowsing, in the Second World War is one of the many reminders of present activities.

Altogether this is a book from which few will not be able to learn. Other writers would perhaps have chosen differently, but with so much available, particularly of recent history, the author must make some selection. Little of importance appears to have escaped his notice, however. The book is illustrated with plates and line-drawings, many of the latter reproduced from memoirs of dates ranging from near its foundation until more than a century later and illustrating some of the more important conclusions reached in that time.

# ANCIENT EGYPT

Ancient Egypt
By J. E. Manchip White. Pp. xii+217+48 plates. (London: Allan Wingate (Publishers), Ltd., 1952.) 21s. net.

THE history of Egypt is unlike that of any other country in the world. For centuries, indeed for millennia, geography imposed so complete an isolation on the region that the evolution of Egyptian culture, especially that of Upper Egypt, became rigidly circumscribed and unaffected by influences from the outside world. The thought of the people throughout centuries of existence seems to have been conditioned by their peculiar natural environment, canalized, almost solidified, and but little influenced by ideas germinated in other civilizations. It is true that, during periods of exceptional governmental weakness, invasions of foreigners did take place; but their effect seems not to have been permanent, and when the central authority once again became strong the invaders were turned out. Perhaps the Biblical account of the ejection of Adam and Eve from Eden is a poetical remembrance of the ejection of the Shepherd Kings from the Nile Delta.

Only when Egypt under the kings of the Eighteenth Dynasty tried to found an empire in Nearer Asia, and for a time succeeded, were the seeds of future final decadence sown. From then onwards, in spite of brilliant flashes of returning vitality, the end became inevitable, and Alexander had few difficulties when he invaded the country—nor had his captain Ptolemy after his death. The contacts with outsiders and their ideas following on these foreign conquests of the earlier years of the New Kingdom sapped fatally the strength of the old Egyptian culture.

The volume under review is written by a poet who has studied archæology, and particularly Egyptology, thoroughly. We get, therefore, the best of both worlds—a knowledge of the available facts and a sensitive appreciation of what old Egyptian life and culture must have been like. The book is not meant for the specialist wanting every detail, but for the informed individual who wishes to realize what life and ideas were like in the remote past in this interesting land. The history of the dynasties is given very briefly in three chapters, but far more pertinent are those on the environment, the Pharaoh, the priest, the aristocrat, the architect, the craftsman and the commoner. There are a number of well-chosen illustrations and the work is an excellent introduction to the study of Egyptology.

MILES BURKITT

## "A IS HAPPY—B IS NOT"?

### British Scientists of the Twentieth Century

By J. G. Crowther. Pp. xiv+320+8 plates. (London: Routledge and Kegan Paul, Ltd., 1952.) 25s. net.

THE theme of this book may be taken in the author's own words: "The parallelism of trends in biology and physics is noticeable, how the Mendel–Morgan genetics and the prostitution of Rutherford's nuclear physics are seen to flourish in the same place, side by side; and, in contrast, how sounder biological theories, together with beneficent applications of atomic energy, are flourishing elsewhere in great constructive works for the dignity and happiness of man".

This *motif* is varied with studies of the lives and works of J. J. Thomson, Rutherford, Jeans, A. S. Eddington, Gowland Hopkins and William Bateson. Excellent portraits of each of these are used to illustrate the book, and a photograph of Academician T. D. Lysenko also appears. With regard to the last, in view of the title of the book, the reader may well ask "Que diable fait-il dans cette galère ?", but a study of the text will soon show why.

The book gives the impression that it is the work of two authors. There is *A*, the gifted writer with a neat and clear style, and with a wide reading in the literature of science, particularly in the biographies and publications of his characters; and there is *B*, the Marxist philosopher, ever seeking an opportunity to despise British intelligence, British institutions and British theoretical physics. Most of the writing is done by *A*, but *B* always has the last word. Some examples will show how this schizophrenic method of biography works itself out.

J. J. Thomson. *A*: "J. J. was not only a teacher and discoverer, he was a creator in the method and organization of research. . . . This world-wide movement of research students to Cambridge was stimulated by the need for science teaching. . . . Unique in the galaxy of J. J.'s collaborators was C. T. R. Wilson. This most admired and Scottish of Scotsmen". *B*: "The cost to mankind as a whole of a leisured life for Newton, Clerk Maxwell and the scores of geniuses who created the subtlety and depth of the Cambridge tradition was great. . . . It is impossible to overlook the adolescent, uncultivated, unintellectual aspects of his mind and school".

Rutherford. *A*: "Rutherford departed suddenly in the midst of a healthy, happy, triumphant and glorious life". *B*: "An unconsciously tragic social figure".

Jeans. *A*: "Why was Jeans so successful as a popular writer? Because he was clear, vivid, confident". *B*: "The enormous circulation of 'The Mysterious Universe' owed much to its meretricious style and shallow philosophical thought. . . . Somehow or other, though, Jeans extracted £256,000 out of society. . . . The character of his writing for the people, revealed the intellectual bankruptcy of the British educated bourgeoisie".

Eddington. *A*: "He regarded his expositions as harmonious works of art and he made them so. It [Eddington's 'unified theory'] may prove to be the boldest, the most imaginative work of the twentieth century". *B*: "It seems probable that it will prove to be an extreme individualist aberration, a product of the weak side of Quaker solitary quietism and obstinacy, which remained uncorrected through the absence of an adequate system of mutual scientific criticism, because of a defect in social organization".

The reader can take what he pleases; but he may be left wondering how the work of Rutherford and Thomson could have been improved had they had the advantages of "an adequate system of mutual scientific criticism" in that Utopia of social organization so beloved by the author. It is, of course, possible that, instead of their superb achievements in experimental physics, they might only have succeeded in developing electric power and illumination had they been subjected to the demands of the party line; similarly, Faraday might have confined his attention to the improvement of the Leyden jar.

> "See how the Fates their gifts allot,
> For A is happy—B is not.
> Yet B is worthy, I dare say,
> Of more prosperity than A".
>
> *The Mikado.*

W. L. SUMNER

## MANAGEMENT AND BIOLOGY OF LIVESTOCK RANGES

### Range Management

Principles and Practices. By Prof. Arthur W. Sampson. Pp. xiv+570. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1952.) 60s. net.

THIS book deals with a subject which, on the surface, might appear to have little interest to the British reader, but there is much in the book to interest students of many sciences as well as agriculturists to whom the book is of especial interest.

A vast subject is covered, and it is impossible to deal in minute detail with every section; but great credit must be given to the writer for the way in which he has selected his material, giving just enough of the scientific background to explain each point sufficiently for the practical man and at the same time to allow the student, who may not be so familiar with the practical aspects, to orientate himself. For the latter who wishes to pursue any section further, there are comprehensive lists of references at the end of each chapter.

The book is divided into four main parts. Part 1, entitled "Range Management in Perspective", deals with the general concept of range management and gives a very concise picture of grazing practices throughout the world and problems which should be of interest to all concerned with the supply of meat and animal products. There follows a consideration of the scientific principles, mainly physiological and ecological, which have an important bearing on range problems, and one is struck by the similarity of many of the problems to some encountered in Britain. This leads to a consideration of some of the aspects of United States grazing, followed by a historical survey.

Part 2 is mainly botanical and deals with the many species of plants which go to make up the range, giving adequate details of the value or otherwise of each. These are classified according to natural orders, and mention must be made of the excellent line illustrations of the plants, many, but by no means all, not commonly seen in Britain. Part 3 deals with the improvement and management of range and stock, starting with the improvement of the herbage, both by natural and artificial reseeding, and the control of noxious woody vegetation. This leads, by way of management and considerations common to both range and range livestock, to livestock choice and management, followed by two chapters on general range management. Again one is struck by the broad similarity of many aspects of the subject to the management of rough grazings in Britain. The final section of the book deals with such subjects as timber and its place on the range, poisonous plants and their control, wild life on the range, soil erosion and, finally, the administration of public grazing lands.

The book will be a useful reference work for advanced students of agriculture, and certain sections will be of more than passing interest to geographers, economists and biologists.

---

# PLANT CELL WALLS

## The Molecular Architecture of Plant Cell Walls

By Dr. R. D. Preston. Pp. xii+211+10 plates. (London: Chapman and Hall, Ltd., 1952.) 36*s.* net.

THE advancing study of the fine structure of plant cell-walls now has an evident relevance to problems of growth, and may also have taxonomic implications; it thus commends itself to general botanical interest. A concise account, from Dr. R. D. Preston, of the essentially botanical (as distinct from the technological) aspects of cell-wall micro-structure is thus a welcome addition to botanical literature.

To the non-specialist, however, his subject presents certain difficulties of approach, derived from its basis in unfamiliar research techniques and modes of thought. Dr. Preston therefore devotes about a third of his book to outlines of the salient features of the chemical and physical structure of cellulose and other cell-wall substances and of the techniques applicable to their study. Special attention is given to the methods of X-ray crystallography and polarization optics, which have proved most fruitful in cell-wall studies. Modern views of the micellar structure of cellulose are explained and discussed in the light of these and other techniques.

Against this physico-chemical background the main theme of the book is developed, largely by reference to the researches of the author and his colleagues. Facts and hypotheses of cell-wall structure and growth are considered in relation to the evidence, and described in terms of the mean orientation, angular dispersion and dimensions of cellulose micelles and microfibrils, and of the nature, proportion and distribution of non-crystalline material in the wall.

Thick cell-walls, having a dense, well-oriented cellulose framework, are described first, by reference to algæ, especially *Valonia*, *Cladophora* and related forms, and to cells of higher plants, especially conifer tracheids and bamboo and other fibres. Such diverse examples, while differing in detail, nevertheless exhibit a certain unity of structure; helical organization, and lamellation of the wall, in varying degrees, are common features. Primary walls are considered separately: here again different examples have a common type of structure; the cellulose framework is more diffuse than in secondary walls and less highly oriented; and protein is present among the non-cellulosic components.

From features of wall structure the author passes to processes of wall growth, of which, as yet, we know little. The growing primary wall is regarded not as a membrane separate from the protoplast, but rather as a differentiated outer layer of the latter, consisting perhaps largely of carbohydrase systems, within which cellulose deposition takes place. It is possible that deposition of the secondary wall may also occur in this way; the complexity, in *Valonia*, of growth in area of an already multi-lamellate wall, without apparent disturbance of its astonishing regularity of structure, seems especially to demand some such relationship. The concept of a definite interface between the protoplast and the wall may thus have to be abandoned. It might be added that cellulose-synthesizing systems external to the protoplast (in the ordinary usage of that term) appear in the activities of *Acetobacterium xylinum* and in the growth of the stalk of the sorocarp of *Dictyostelium*; they may well thus be of wider occurrence.

Further problems arise in the relationship between wall structure and cell shape. A detailed consideration shows that they are not simply related mechanically as has sometimes been supposed, but must be regarded as consequences of different aspects of cytoplasmic organization of which our appreciation is as yet speculative, but towards an understanding of which future cell-wall studies will extend.

In its conception, and in the broader aspects of its presentation, this is a valuable and stimulating book. The detailed exposition is, however, marred by a certain lack of coherence and an inexactness of style which make for unnecessary difficulties. This appears in the arrangement of the physical sections and in ambiguities such as the conflicting statements on pp. 48 and 71 concerning molecules and micelles; the confusion on p. 67 between $n_\gamma$ and $n_\gamma'$ (not apparently a mere misprint) in relation to the degree of crystallinity; and the reference on p. 140 to "cellulose micelles . . . (of) low cellulose content"—to cite but three examples among many. There are also some misprints which lead to confusion.

The book is generously illustrated, though in some instances the half-tone reproduction is inadequate. There is a bibliography of some hundred and twenty titles.

K. Wilson

# THE SECOND CŒLACANTH

By Prof. J. L. B. SMITH

South African Council for Scientific and Industrial Research, Fellow in Ichthyology, Rhodes University, Grahamstown

IT is my great privilege to announce the discovery of a second Cœlacanth. There are few biologists who do not remember the amazement engendered by the appearance of *Latimeria* Smith, 1939, as well as the acute disappointment in learning that all the soft parts of the fish had been lost.

For these various reasons it became a self-appointed task to endeavour to find a complete specimen, and for almost fourteen years I have constantly pursued that aim. There was overwhelming evidence that the fish was a stray, so that the first essential was to attempt to trace the habitat.

The only overseas scientist to venture an opinion on this matter was E. White, of the British Museum, whose statement that it was "almost certainly" from "the deeper parts of the sea, to which its kind have retreated in the face of fierce competition with the more active modern types of fish", scarcely took into account that numbers of successful modern fishes, some quite numerous, appear less well equipped for survival than the Cœlacanth, and a fish from the depths so well armoured would from our present knowledge indeed be a phenomenon.

From my study of fishes the Cœlacanth appeared to be a denizen of moderately deep water, living in and about rocks, presumably in an area not easily fished or commonly fished with efficiency.

My studies led me to regard the Mozambique channel about Madagascar as the most likely area, and plans for an expedition to search for more were well advanced, but fell through. I then decided on another method, and a leaflet, in English, French and Portuguese, was prepared, giving a brief account, and a photograph of the Cœlacanth, as well as offering a reward of £100 for each of the first two specimens caught.

By co-operation of the respective authorities, thousands of these leaflets were distributed throughout the coastal regions of the Western Indian Ocean, in such fashion that they reached and were explained to the native fisherfolk in even the most remote parts. During the past six years my wife and I have carried out expeditions along a considerable part of the East African coast, covering many otherwise inaccessible parts on foot. We continually spoke of the Cœlacanth and emphasized its importance, to all classes and races, and distributed leaflets. It is more than gratifying that this has led directly to the discovery, at the Island of Anjouan in the Comoro Archipelago, of the new Cœlacanth described below. The European responsible for saving the specimen was Captain E. E. Hunt, to whose trading schooner it was brought. Circumstances were such that I was compelled to fly to Pamanzi Island to retrieve the specimen, a military Dakota aircraft being provided by order of the Prime Minister, Dr. D. F. Malan. The return journey from and to Durban was completed in thirty-seven hours.

The native recipient of the £100 reward caught the fish in the evening of December 20, 1952, on a fish-baited hook, at a depth of about eight fathoms on rocky ground some 200 metres from shore off the village of Domoni, at about lat. 12° 15′ S., long. 44° 33′ E. He killed it by blows on the head. At the market next day the fish was saved from being cut up by a native who recognized it from our leaflet. It was then carried across the Island to Hunt, then at Mutsamudu village.

Having no formalin, he ordered his natives to cut it for salting, which they unfortunately did by slicing it all along the back from snout tip to tail, thereby destroying the brain and other soft parts of the head, and cutting through the gullet and axial structures. Hunt then went to Pamanzi, where he got and injected formalin. During my short time at Pamanzi he informed me that the specimen was intact, that no part had been removed. I have only in the past few days had time to examine the creature more carefully, and it is most disturbing to find that the head is shockingly battered and the body roughly and widely lacerated. On the other hand, it is apparently only the soft parts of the head, chiefly the brain, that have been lost.

This is not as disastrous as may appear, for it is more than counterbalanced by the fact that the home of at least one species of Cœlacanth has been found. The natives there know the Cœlacanth well and assert that one or two a year have been caught in that same locality regularly as far back as they know. It is likely, therefore, that over the whole archipelago more must be caught, and it should not be long before a perfect specimen can be obtained. The natives speak also of a constantly smaller Cœlacanth, which may well prove to be different, and it will in any event not be surprising if further species exist; nor is there any reason why they should not occur in other parts of the world as well. From what can be ascertained, the Cœlacanths can scarcely be regarded as degenerate fish. They are apparently full of vigour.

This fish clearly represents a new genus, and *Malania* nov. gen. is proposed, in honour of the Prime Minister of South Africa, Dr. D. F. Malan, whose prompt decision and commendable action at that late stage saved the fish. I had intended to name the species after Captain Hunt, but he preferred that it should mark the locality where the fish was caught, hence *Malania anjouanae* gen. et sp. nov.

Owing to a printer's error, *Melania* Perry, 1811, appeared as *Malania* in Preston, *Rev. Zool. Afric.*, 1913. As there is no connexion whatever between *Melania* and *Malania*, it appears reasonable that the latter should be valid, as a generic name, for the present fish. If *Malania* is ruled as invalid, I propose the generic name *Malanius* to replace it.

## Family Latimeriidæ

The specimen of which an outline account follows resembles *Latimeria* Smith, 1939, in general facies, but is only provisionally referred to this family. A more detailed investigation may lead to other conclusions. Of interest is the presence of a well-developed spiral valve, the presence of which had been suspected in forms now regarded as extinct.

## Genus *Malania* nov.

### Genotype *anjouanae* sp. nov.

This genus superficially resembles *Latimeria* Smith, 1939, and is clearly derived from the same ancestral

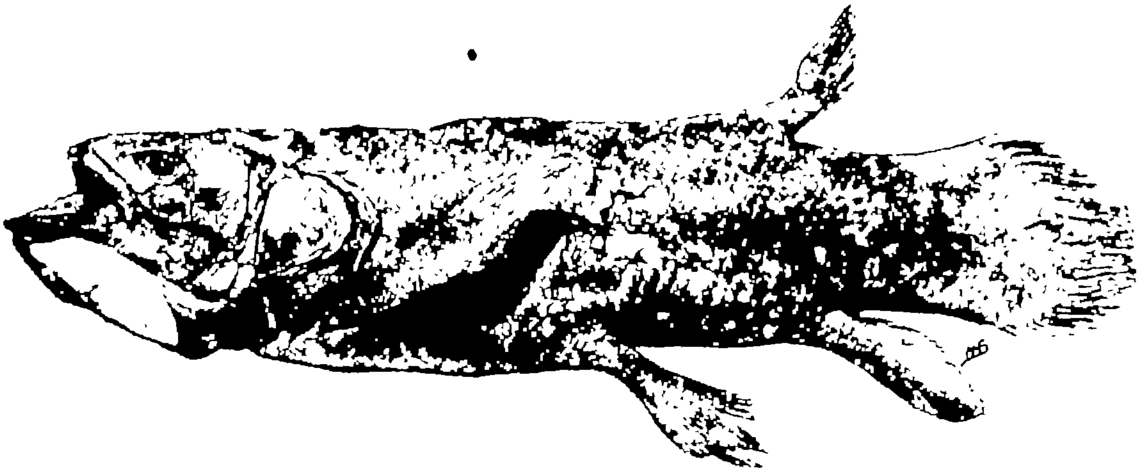

Fig. 1. *Malania anjouanae* gen. et sp. nov Type Male Actual length, 1,385 mm.

type. As far as may be determined, the main surface bones of the head are very much like those of *Latimeria*; but there are differences in the smaller structures.

Immediately apparent is the absence of a supplementary caudal and of a first dorsal. The basal plate of the latter fish is present, and it is at least possible that the fin itself may have been lost by injury in early youth. That particular area of skin was mutilated in cutting; but the adjacent scaling has the appearance of having grown abnormally, as would occur in covering a scar.

The ossifications in this fish appear to be less dense than in *Latimeria*.

The whole fish is extremely oily, especially the dermal structures.

There are numerous other structural distinctions, as yet not fully worked out, which may necessitate separation by family rank for this form. These will be described later in a more detailed monograph on the specimen.

The scales are much like those of *Latimeria*, but smaller, and the tubercles are not so marked. There are 33 series to the level of the origin of second dorsal, 56 to caudal origin and 68 to caudal base.

*The Head*

The major dermal ossifications appear to be much the same as in *Latimeria*, the opercular, the post-orbital, the squamosal, the preopercular and the lacrimo-jugal being almost identical in shape and position. There is no trace of the small ossification provisionally identified as an inter- or sub-opercular in *Latimeria*.

*Mouth Parts*

The dentigerous structures are in every way comparable with those of *Latimeria*, but the anterior tooth plates are smaller and less clearly distinct from one another. The teeth on the whole are smaller, and there are more granular than sharp teeth.

### *Malania anjouanae* sp. nov.

The specimen has a total length of 1,385 mm. The body is robust and moderately compressed, increasingly so posteriorly.

The first dorsal is represented only by the basal plate beneath the skin. The second dorsal is relatively smaller than in *Latimeria*, while the pectoral is somewhat similar. The pelvic in *anjouanae* is broader than in *Latimeria*, and there is a fringe of separate elongate rays along the inner hinder margin, the hindmost few again connected by membrane, forming a slight lobe that folds back over the anus and is in some respects reminiscent of the elasmobranch 'clasper'.

The anal fin is much like that of *Latimeria*.

The caudal is almost symmetrical and lacks any sign of the axial supplement. The rays are all spinose, increasingly so anteriorly.

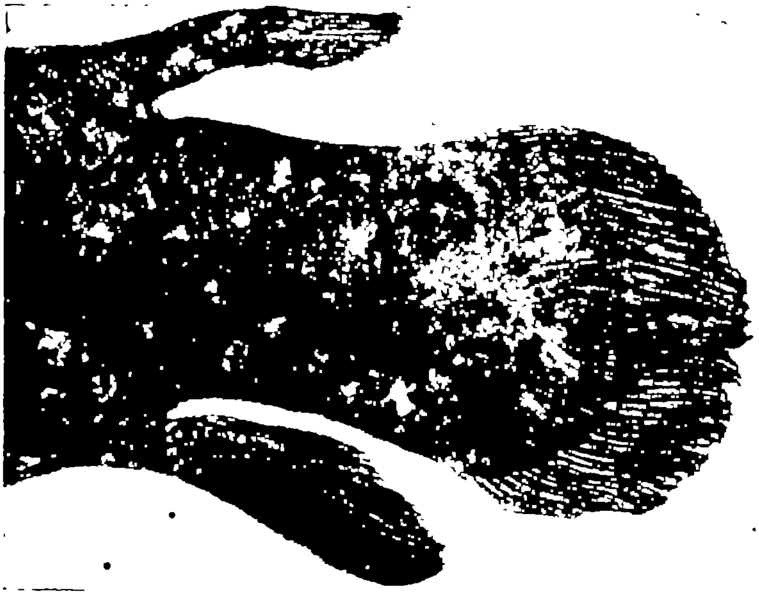

Fig. 2. *Malania anjouanae* gen. et sp. nov. Caudal Actual length, 560 mm.

The suspension of the lower jaw appears to diverge considerably from that of *Latimeria*, but time does not permit of more detailed investigation at present.

There is no sign of any internal narial opening.

*Copula and Gills*

The copula is much like that of *Latimeria*, and situated much as deduced for that fish[1]. There are five gill-arches, but, as deduced for *Latimeria*, only four are attached to the copula; the smaller fifth is behind. There is no slit behind the last gill. Well-marked pseudo-branchiæ are present. The gill-arches are hollow, flat, boomerang-shaped plates, the lamina formed by inverted U-shaped, thin, but strong bone, with a rod-like bony structure running inside along the dorsal margin. The outer arch is 35 mm. wide at the angle and about 8 mm. in thickness. Each side of the top of each arch bears two series of numerous fairly small plates, each beset with stout sharp spines. Mostly there is one large spine, almost a canine tooth, on each plate, together with small spines of varying size and number. The large spines on the outer face of the first gill-arch point upwards. The gill filaments are attached to the approximating but not touching lower edges of the bone, and at the angle are about 30 mm. in length, longer on the hinder limb of the arch.

*Rostral Papilla*

This is almost exactly as in *Latimeria*.

*Brain Case*

In regard to the nature and structure of the median rostral cavity and the relation of the three external "narial openings", described for *Latimeria*[1], doubts have been expressed about the accuracy of those observations by Jarvik[2]. *Malania* has exactly the same system in every respect as that described for *Latimeria*. The three external openings communicate directly with the median rostral cavity, and with nowhere else, and that cavity appears to have no direct connexion whatever with the brain.

The lateral fossæ of this median cavity, leading to the lateral openings, are completely filled with an oily jelly-like substance, and the mouth of each of the fossæ appears to have been completely closed by a stout membrane, cutting off all connexion with the outside. My observation on *Latimeria* of the possibility of water passing through the cavity is thus invalid.

Jarvik's statement[2] that I maintained this system as having something to do with the olfactory system of Cyclostomes is not correct.

The actual brain cavity is almost exactly as for *Latimeria*, and so far as may be observed at present, the 'olfactory' lobes of the brain do not communicate directly with any aperture on the snout.

*Axial Skeleton*

The notochord is massive and entirely cartilaginous, the walls being quite soft and about 8 mm. thick. The tube is about 40 mm. internal diameter at its widest part, tapering posteriorly. It had been hacked through roughly by Hunt's natives, so the contents are lost. The anterior end curves up, then down, to end in an imperforate fossa in the posterior ossified cranial wall.

On the anterior and on the posterior parts of the sheath are neural and hæmal processes, the shape of which there has been no time to determine, but they seem to be cartilaginous. They appear to be few or absent along most of the central part of the sheath.

*Abdominal Viscera*

Brief examination shows that the intestinal canal is comparatively short. The gullet merges into a long stomach the posterior end of which is well behind the anus. Near the anterior end of the stomach is a wide pyloric aperture, leading to a comparatively short and slender 'duodenum' about 7 in. in length, which runs anteriorly from the pylorus. At its anterior end there is a sharp reverse flexure, which is the anterior part of a 9-in. long, fairly slender, more or less fusiform spiral valve, of apparently complex structure, with six or seven revolutions in its length. The gut issuing from the valve is about 9 in. in length, slender and simple, running direct to the anus. Attached to almost the whole length of the spiral valve is an elongate sub-nodular organ, a pancreas, or its antecedent, apparently discharging into the anterior end of the spiral valve.

The fish is a male, the paired testes being about 7 in. in length, long, slender subfusiform, and partly segmented and entirely posterior to the anus. I can discern no clear indication of any structure which may be regarded as an intromittent organ, but on the external parts of the genital opening there appear to be two large flat fleshy papillæ. The urogenital opening is large and lies immediately behind and between the pelvic bases.

In the intestine were found the two eyeballs of a fish and some scales. The former indicate a fish prey of possibly 2 ft. in length.

The liver is of curious appearance, almost black, elongate, sub-cylindrical, the left lobe reaching two-thirds of the length of the cavity, the right shorter, about three-fifths of the left. This has not yet been investigated.

I wish to pay tribute to our Prime Minister, Dr. D. F. Malan, for his prompt response to my appeal for assistance to fetch this fish from the Comoro Islands. Also to M. Pierre Pierre Coudert, Governor of the Comoro Archipelago, for his cordial co-operation. Captain E. E. Hunt deserves every credit, first for having taken the trouble to learn as much as possible about Cœlacanths, and also for having saved what he did under great difficulties.

# A. A. MICHELSON, 1852–1931

By Prof. R. S. SHANKLAND

Case Institute of Technology, Cleveland, Ohio

THE Cleveland Physics Society met on December 19, 1952, to commemorate the centenary of the birth of Albert A. Michelson and to dedicate a plaque in memory of the Michelson–Morley experiment. The plaque was presented by the Case Institute of Technology and the Western Reserve University, and is to be erected in Cleveland, Ohio, on the line between their adjacent campuses near the spot where the Michelson–Morley experiment was performed.

Michelson was born on December 19, 1852, in Strelno, Germany, now Strezelno, Poland. When he was two years old the family moved to California, where Michelson finished his high-school education in San Francisco, and in 1869 he entered the United States Naval Academy at Annapolis on a special appointment from President Grant. He graduated in the class of 1873 and, following the usual cruises as a past midshipman, served during 1875–79 as instructor in physics and chemistry at the Naval Academy.

While at Annapolis in 1877, Michelson made his first measurement of the speed of light, employing an important improvement which he had made on Foucault's rotating-mirror method. This work led to his association, in 1880, with Simon Newcomb at the Nautical Almanac Office, Washington, D.C., where they collaborated in further measurements of the speed of light. In September 1880 Michelson went to Europe and for two years studied and carried out research at Paris, Heidelberg, Berlin and Potsdam, and it was while at the Collège de France in 1880 that he invented the Michelson interferometer as a means for measuring the earth's motion through the æther. His interest in this problem had been aroused by a letter from James Clerk Maxwell to D. P. Todd, who was director of the Nautical Almanac Office during Michelson's appointment there. Maxwell had emphasized that all experiments attempting to observe the earth's motion through the æther, which depended on measuring the first power of the ratio of the earth's speed to that of light, were doomed to failure. He went on to say that no terrestrial experiment for measuring the velocity of light could detect the earth's motion in space, since "in the terrestrial methods of determining the velocity of light, the light comes back along the same path again, so that the velocity of the earth with respect to the ether would alter the time of the double passage by a quantity depending on the square of the ratio of the earth's velocity to that of light, and this is quite too small to be observed"[1]. Michelson's interferometer and the 'Michelson experiment' which he devised were the direct results of this challenge by Maxwell. The first trial of the experiment was made in Helmholtz's laboratory in the University of Berlin; but street traffic made observations impossible. The interferometer was therefore removed to Potsdam where, in April 1881, a second trial was made at the Astrophysical Observatory. The experiment gave a null result[2]; but, as the expected effect due to the motion of the earth in its orbit was only a shift of 0·04 of a fringe when the interferometer was rotated through 90° in the horizontal plane, this result was never considered conclusive, especially by Michelson himself[3].

In September 1882 Michelson went to Cleveland and began his duties as professor of physics in the Case School of Applied Science (now Case Institute of Technology). He had been appointed on March 28, 1881, but had been granted leave to remain in Europe until his researches there were completed. During his first two years in Cleveland, Michelson made further measurements on the speed of light, obtaining 299,853 ± 60 km./sec. for the value reduced to a vacuum, which was the most reliable measure until 1927. He also discovered the difference between phase and group velocities of light in carbon disulphide, this being the first experimental confirmation of Lord Rayleigh's dispersion theory for this effect[4].

Interest in the æther problem was revived when Michelson and Edward W. Morley, professor of chemistry and natural history in the Western Reserve University, Cleveland, attended the series of lectures by Lord Kelvin (then Sir William Thomson) on "Molecular Dynamics and the Wave Theory of Light" given at the Johns Hopkins University, Baltimore, during October 1884. Lord Rayleigh was also present for part of these lectures, and both he and Kelvin urged that a new trial of the Potsdam experiment be undertaken. Thus began the collaboration of Michelson and Morley. Their first work together, however, was not to repeat the Potsdam experiment, but to carry out in greatly improved fashion Fizeau's experiment on the speed of light in moving water[5]. At that time Fizeau's result was considered to be in conflict with Michelson's Potsdam experiment, and there seems to have been considerable doubt as to its validity. As all theoretical treatments of the æther problem involved Fizeau's 1851 measurement of the Fresnel dragging coefficient, it was felt that a new experiment should be performed to subject this question to a decisive test. By employing a modified form of the Michelson interferometer, greatly improved optics, compared to those available to Fizeau, were brought into play, and with other refinements for controlling and measuring the water flow they obtained a result[6] in very close agreement with the Fresnel theory and also with the more precise and satisfying formulation given by the Lorentz "Theory of Electrons"[7].

After completing this work in 1886, Michelson and Morley undertook the investigation which has since been known as the Michelson–Morley experiment, employing for this a greatly improved Michelson interferometer compared to that used at Potsdam. The optical paths were lengthened by multiple reflexion of the light beams so that the expected effect due to the earth's orbital motion was increased from 0·04 to 0·4 of a fringe. For greater stability, freedom from vibration and ease of rotation, the optical system was mounted on a sandstone slab 150 cm. square and 30 cm. thick, which was supported on an annular float in an annular trough full of mercury. The work with this apparatus continued from 1886 until July 1887 and was conducted in buildings on the adjacent Case and Western Reserve campuses. The definitive null result obtained in these experiments[8] led to profound changes in the development of physics. The contraction hypothesis of G. F. FitzGerald was the first serious attempt to explain the result of Michelson and Morley, and this contraction, together with the concept of 'local time', was elaborated in Lorentz's revised "Theory of Electrons" to provide an adequate but rather artificial interpretation for the Michelson–Morley experiment[7]. It is needless to say that the most direct and now universally accepted explanation for the Michelson–Morley experiment, as well as for the Fizeau experiment and the phenomena of astronomical aberration, is provided by the special theory of relativity given by Albert Einstein in 1905 [9].

The collaboration of Michelson and Morley continued during 1887–89 when they established the feasibility of making the light wave the ultimate standard of length, a programme which was carried to completion by Michelson in Paris in 1892. In the course of this investigation, they discovered the fine structure of the red hydrogen and other Balmer lines and the hyperfine structure in the spectrum of mercury[10]. Later, Morley conducted his notable determinations of the atomic weights of oxygen and hydrogen, and Michelson, first at Clark University and then for many years at the University of Chicago and at the Lick and Mount Wilson Observatories, carried on his many famous investigations in spectra and optical metrology.

# INTERACTION OF CHLORINE DIOXIDE WITH FLOUR: CERTAIN CHEMICAL ASPECTS

By Dr. T. MORAN, C.B.E., Dr. J. PACE and E. E. McDERMOTT

**Research Association of British Flour-Millers, Cereals Research Station, St. Albans**

FOLLOWING the discovery that agene-treated flour could produce hysteria in dogs and certain other animals, the whole question of flour improvers is being very carefully considered in many countries. It is clearly essential that an improver should not only meet the technical requirements necessary for present-day methods and standards of bread-making, but should also be completely acceptable from the point of view of public health. In the United States, chlorine dioxide has replaced agene as the more commonly used improver. This decision was taken after extensive feeding experiments with dogs, rabbits, rats, monkeys and human beings[1,2] had shown no clinical evidence of acute toxic symptoms or abnormalities in any of the species tested.

The feeding trials carried out in the United States are reassuring; such investigations are an essential first step in deciding whether or not the interaction of flour with chlorine dioxide could lead to the formation of deleterious substances. In a problem of this character, however, there are certain limitations in such animal-feeding tests. The gaseous flour improvers are applied at very low concentrations; chlorine dioxide at about 30 parts per million. They may interact with a number of the constituents of flour and not exclusively with one. There is the possibility, therefore, that flour treated with an improver may contain traces of a number of unknown substances, without necessarily reducing significantly the amount of any one essential metabolite. In these circumstances the overall composition of the experimental diet used in the tests may be decisively important. A certain diet may, for example, accentuate the effect of a deleterious factor or it may neutralize it. Thus, in our work with methionine sulphoximine, the agene toxic factor, we encountered an example[3] of a change in the dietary of rabbits neutralizing the toxic effect of sulphoximine. Again, since the chemical nature of any new substance is unknown, it is not possible to plan dietaries with which neutralizing or masking effects will be minimized.

In our opinion, it is important, in studies on the effect of chemical treatment of food, to supplement the essential biological tests with biochemical investigations. If it is possible to identify modified substances, then these may be studied in animal-feeding trials and their effect observed on isolated enzyme systems. Because of the importance of flour as a staple article of diet, we consider both types of investigation—tests with animals and chemical studies—to be essential. In addition to animal-feeding tests, which are continuing, we have investigated some of the interactions which occur between chlorine dioxide and flour and fractions derived from flour. This article summarizes the observations we have so far made. It is hoped to publish elsewhere a more detailed account of the methods and techniques used. Both pure chlorine dioxide and chlorine dioxide containing approximately 30 per cent chlorine have been used.

## Interaction with the Lipoids of Flour

The lipoids of flour interact readily with chlorine dioxide and with chlorine. With pure chlorine dioxide, the unsaturated fatty acids are the initial sites of an oxidative process which appears to include some degree of polymerization. The iodine number of fat extracted from 81 per cent extraction flour is about 112, whereas that of fat extracted from similar flour treated with chlorine dioxide, at ten times the commercial level, is about 103. If a solution of this 'treated' fat in petroleum ether is kept at room temperature, there is a slow deposition of an insoluble rubber-like polymer. The initial oxidation reaction with unsaturated fatty acids is observed both at commercial levels of treatment and at higher levels. This has been demonstrated by an adaptation of the method of Wilbur, Bernheim and Shapiro[4], who have shown that thiobarbituric acid is a sensitive reagent for detecting autoxidation and catalysed oxidation of unsaturated fatty acids in biological material. The products of oxidation when treated with the thiobarbituric reagent give a pink colour with a characteristic absorption spectrum. Table 1 records observations made with flour treated with a number of improvers, and with untreated flour.

From these results it will be noted that untreated flour three months old may have an oxidation value, as shown by the thiobarbituric test, either less or greater than that of flour treated with chlorine dioxide at the commercial level. Different flours apparently vary in this respect, presumably because

Table 1

| | Material tested: 81 per cent extraction flour | Colour with thiobarbituric reagent |
|---|---|---|
| (I) All the same Manitoba flour | (1) Treated with chlorine dioxide at 10 times commercial level | Strong orange pink |
| | (2) Treated with agene at 10 times commercial level | Strong orange pink |
| | (3) Treated with bromate at 10 times commercial level | Very faint pink |
| | (4) Treated with persulphate at 10 times commercial level | Slight pink (> No. 3) |
| | (5) Treated with chlorine dioxide at the commercial level | Pink (< No. 1 but > No. 4) |
| | (6) Untreated flour 3 months old | Similar to No 3: very faint pink |
| (II) Mixed grist flour | (7) Treated with chlorine dioxide and chlorine at the commercial level | Very faint pink (< No. 9) |
| | (8) Treated with chlorine dioxide and chlorine at 10 times commercial level | Strong orange pink |
| | (9) Untreated flour 3 months old | Very faint pink |
| Manitoba flour as in (I) | (10) Untreated flour 12 months | Pink (> No 9) |

of varying content of natural anti-oxidant substances. An untreated flour, twelve months old, has a considerably higher value than flour treated with chlorine dioxide at the commercial level. Whether the polymerization effect, noted with fat extracted from flour treated at ten times the commercial level, is also observed with an aged flour, for example, nine to twelve months old, has not yet been investigated.

There is no significant chlorination of the fat when pure chlorine dioxide is applied to flour, and most of the chlorine originally bound in the chlorine dioxide molecule appears ultimately in the form of water-soluble chloride. If the gas applied contains free chlorine, there is chlorination of the fat. As much as 40 per cent of the chlorine applied may be found in the fat extractable from the flour with petroleum ether.

The oxidation (or peroxidation) of lipoids by chlorine dioxide or air may be an important primary step in a sequence of oxidative changes affecting other flour constituents. In this connexion, if the fat from flour treated with chlorine dioxide at ten times the commercial level is deposited on kieselguhr together with methionine and the mixture kept in the dark, the methionine is oxidized almost completely to methionine sulphoxide with a little of the sulphone. With fat from untreated flour under similar conditions there is no significant oxidation of the methionine within the same period of time. This observation, of a non-enzymatic transfer of oxygen, may be of interest in other fields of work connected with food and nutrition. In relation to the present problem it has led us to pay particular attention, in the work on protein fractions, to the lipo-protein complexes which may be obtained from petroleum ether extracts of flour.

## Reaction with Tocopherols

Flour containing wheat germ, for example, flour of 81 per cent extraction, is a useful source of vitamin E. In view of the oxidative effect of chlorine dioxide on fat, and the sensitivity of this fat-soluble vitamin to oxidation, some observations have been made on the stability of tocopherols in flour to treatment with chlorine dioxide. These have been made on the flour stream rich in germ from a commercial mill before and after chlorine dioxide treatment under commercial conditions. A chemical estimation of total tocopherols has been used, based essentially on Parker and McFarlane's[4] adaptation of the Emmerie–Engell method but modified by using the last stage of the Wall and Kelley[5] procedure. The tocopherol content of the treated flour was reduced by about 70 per cent compared with the untreated flour. The nature of the oxidation products has not been investigated, and we have not yet carried out tests with animals to examine whether or not they have retained any biological activity similar to that of vitamin E.

## Interactions with Proteins

Many of the amino-acids readily react with oxidizing agents and halogens. When they are linked together by peptide bonds, as in proteins, their reactivity may differ, compared with when they are free, and the type of reaction may be different. Only those residues at the end of peptide chains will have free α-amino or carboxyl groups. Reaction with the side-chains may also be influenced by the presence and nature of the neighbouring groups, by the spatial configuration of the various residues in the peptide chains, and by interchain bonding. In this connexion it is interesting to recall that the agene toxic factor, methionine sulphoximine, is not formed when free methionine reacts with nitrogen trichloride but only when methionine is a component residue in a protein. It also follows that similar residues or groups within a given protein may differ in their reactivity and also, of course, in their reactivity in one protein compared with another. It is therefore useful to examine hydrolysates from different types of proteins which have interacted with chlorine dioxide.

For the immediate purpose it would suffice to consider the total protein of flour, as this would include a variety of types of protein. But this would involve hydrolysis of whole flour, and the presence of so much carbohydrate leads to losses of an unknown order and favours the production of artefacts. Another approach would be simply to compare the gluten from treated and untreated flour. It is not, however, possible to wash out a gluten, from flour treated with chlorine dioxide at ten times the commercial level, which is comparable with that from untreated flour. For these reasons we have, in addition to comparing fractions from treated flour with similar fractions from untreated flour, also isolated fractions and then treated them directly with chlorine dioxide. There are a number of limitations to be noted. First, we have worked with totally hydrolysed protein fractions. Therefore we should not detect any modified amino-acids which are unstable to conditions of total acid hydrolysis. Secondly, our final observations have been made with paper chromatograms using ninhydrin. We should not, therefore, detect any substances present which do not give a colour on the paper chromatogram with this reagent.

Hydrolysates have been fractionated by ionophoresis in a four-compartment cell of the type described by Synge[7], displacement chromatography on ion-exchange resins and, occasionally, on kieselguhr partition chromatograms. Fractions at different stages have been examined on two-way paper chromatograms. In all cases the appropriate untreated fraction has been examined by the same procedure as the treated fraction. Table 2 records amino-acids observed in treated material but not in untreated material. Methionine sulphoxide is only noted if present in significantly greater amount than in the control.

In some of the examples given in Table 2 we have calculated the amounts of modified amino-acids formed (see Table 3). This has been done by comparisons, on paper chromatograms, with known amounts of the appropriate substances. The calculations are admittedly rough but they give an idea of the order.

The levels of treatment with chlorine dioxide which have been employed in this work are considerably higher—in some cases fantastically higher—than those normally used in the commercial mill. This, however, is a reasonable first approach in investigations which have a toxicological aspect, and it was used successfully in our work on the isolation of the agene toxic factor[8]. Furthermore, the present study has been chiefly concerned with noting the types of reaction which are most likely to occur and which are most readily detected. It has also been our experience that the same reactions occur at different levels of treatment, though of course they are progressively less as the level of treatment is reduced. At commercial levels of treatment the production of modified amino-acids, for example, will

Table 2

| Protein fraction | Treatment | Modified amino-acids found |
|---|---|---|
| (1) *Gliadin* prepared from untreated flour (75% extraction) | Gliadin preparation saturated with ClO$_2$/Cl$_2$ absorbed 2,400 mgm./100 gm. | Monochlortyrosine, dichlortyrosine, methionine sulphone, methionine sulphoxide |
| (2) *Gliadin* extracted from treated flour (75% extraction) | Flour treated with ClO$_2$/Cl$_2$ at 7·9 mgm./100 gm. | Methionine sulphoxide |
| (3) *Gliadin* extracted from treated flour (81% extraction) | Flour treated with pure ClO$_2$ at 29·6 mgm./100 gm. | Methionine sulphoxide |
| (4) *Gliadin* prepared from untreated flour (81% extraction) | Gliadin preparation treated with ClO$_2$ containing 0·08% Cl$_2$ at 560 mgm./100 gm. | Methionine sulphone, monochlortyrosine |
| (5) *Zein* (Corn Products Co.) | Saturated with ClO$_2$/Cl$_2$ absorbed 2,400 mgm./100 gm. | Methionine sulphoxide, methionine sulphone, monochlortyrosine |
| (6) *Lipoprotein complex* extracted from treated flour (81% extraction) | Flour treated with pure ClO$_2$ at 79 mgm./100 gm. | Methionine sulphone |
| (7) *Lipoprotein complex* extracted from treated flour (81% extraction) | Flour treated with pure ClO$_2$ at 29·6 mgm./100 gm. | Methionine sulphone |
| (8) *Lipoprotein complex* extracted from untreated flour | Lipoprotein preparation treated with ClO$_2$ containing 1% Cl$_2$ at 2,730 mgm./100 gm. | Methionine sulphone, monochlortyrosine |
| (9) *Lipoprotein complex* extracted from untreated flour (81% extraction) | Lipoprotein preparation treated with pure ClO$_2$ at 2,900 mgm./100 gm. | Methionine sulphone, cysteic acid, one unidentified substance |
| (10) *Lipoprotein complex* extracted from treated wheat germ | Wheat germ saturated with ClO$_2$/Cl$_2$ | Methionine sulphone cysteic acid, monochlortyrosine, dichlortyrosine, one unidentified substance.<br>Ethanolamine reduced by about 50% |
| (11) *Lipoprotein complex* extracted from treated flour (81% extraction) | Flour treated with ClO$_2$/Cl$_2$ at 40 mgm./100 gm. | Methionine sulphone, monochlortyrosine |
| (12) *Lipoprotein complex* extracted from germ-rich stream from commercial mill | Flour stream had been treated with ClO$_2$/Cl$_2$ at usual commercial level for this stream | Monochlortyrosine, methionine sulphone, cysteic acid |
| (13) *Albumin-type protein* extracted from treated wheat germ | Wheat germ saturated with ClO$_2$/Cl$_2$ | Methionine sulphone, cysteic acid, monochlortyrosine, dichlortyrosine |

The normal commercial treatment of flour averages 3 mgm./100 gm. flour

be of an extremely low order, and therefore difficult if not impossible to detect with the experimental techniques at our disposal.

The amino-acid residues which are attacked, in a variety of protein fractions, and which give ninhydrin-positive modifications which are stable to total acid hydrolysis, are methionine, cysteine and tyrosine. These may, in fact, be the most susceptible in the intact protein; but this cannot be considered as completely established by the present work, as other amino-acid residues may be equally susceptible to attack, though, as already stated, the products may be either unstable to acid hydrolysis or may fail to give a colour with the ninhydrin reagent. If pure chlorine dioxide is used, oxidation reactions predominate, with the formation of cysteic acid and the oxides of methionine. If free chlorine is also present, then halogenation occurs, and in these circumstances we have usually noted the presence of monochlortyrosine and, at higher levels, dichlortyrosine. In none of the protein fractions treated with chlorine dioxide, or derived from treated flour, have we observed the presence of the agene toxic factor—methionine sulphoximine.

It would obviously be easier to comment on the practical significance of this work when more results have been accumulated by other workers and by ourselves. As, however, the question is regarded as of urgent national importance, we have considered that we should record the results we have so far obtained. If, however, they are presented without some expression of our opinion of their significance, they may be given interpretations to which we should not necessarily subscribe. This possibility arises because the whole question of chemical additions to food is controversial and widely debated. For these reasons a brief comment appears desirable.

Table 3

| Fraction as described in Table 2 above | Modified amino-acid found | Estimated amount of modified amino-acid present | |
|---|---|---|---|
| | | per cent of protein fraction | p.p.m. in flour |
| 6 | Methionine sulphone | 0·1 | 0·12 |
| 8 | Monochlortyrosine | 0·1 | |
| 9 | Methionine sulphone | 2·0 | |
| | Cysteic acid | 1·0 | |
| 12 | Monochlortyrosine | 0·01 | 0·001 |

At commercial levels of treatment with chlorine dioxide, the production of the modified amino-acids which we have observed is quantitatively so small that the reduction in the content of the parent amino-acids is certainly negligible. Again, because of the very low concentration of these modified amino-acids, it also follows that they are unlikely to induce toxic symptoms unless they are extremely potent anti-metabolites such as methionine sulphoximine. So far as we have been able to ascertain from our own limited feeding trials, they have no such acute toxic properties. Methionine sulphoxide is the most readily produced modification of those we have observed, and we have noted that this substance is present, at concentrations approaching those to be expected with commercial chlorine dioxide treatment, in *untreated* samples open to ordinary atmospheric oxidation. The chlortyrosines have not been observed when chlorine dioxide free from chlorine was used.

Judged by the thiobarbituric acid test, the degree of oxidation of unsaturated fatty acids by chlorine dioxide, applied at commercial levels, may be no greater than is observed with some flours (untreated) which are three months old, and considerably less than with untreated flour twelve months old. We do not yet know whether the fat extracted from such aged flour undergoes polymerization similar to that observed with fat from flour treated with chlorine dioxide at ten times the commercial level.

The reduction in tocopherol content should be assessed, by the appropriate authorities, in relation to the overall supply of vitamin E in the dietary. We consider that this aspect of the work requires further investigation, using biological tests, primarily to ascertain whether or not the oxidation products may have an anti-vitamin E activity.

# FORTIETH ANNIVERSARY OF THE DISCOVERY OF X-RAY DIFFRACTION

WHEN Max Laue, then a young *Privatdozent* at the University of Munich, saw, early in 1912, the successful result of the attempt made at his request by Friedrich and Knipping to diffract X-rays by a crystal grating, he could scarcely have imagined the effect that this success would have on so many and so varied branches of science, followed as it was to be by the opening up of X-ray spectroscopy and crystal structure analysis by W. H. and W. L. Bragg. A tribute to this fundamental work of Laue was given by the X-ray Analysis Group of the Institute of Physics, at the instance of the British National Committee for Crystallography, by the arrangement of a special meeting held in London at the Royal Institution during October 24–25[*], with an anniversary dinner in London. Many famous figures were able to attend this meeting, and many of them spoke, either during the meeting or at the dinner, including Prof. von Laue himself, Sir Lawrence Bragg, Sir Charles Darwin, Prof. J. D. Bernal, Prof. J. M. Bijvoet, Dr. C. Sykes, Dr. Dorothy Hodgkin and Prof. G. V. Raynor. To complete the picture, a congratulatory message from the American Crystallographic Association, sent by Prof. P. P. Ewald, himself one of those associated with the early work of Laue, was read out by the chairman of the Group, Dr. W. H. Taylor, before the meeting began.

The first session began with an account, given by Sir Lawrence Bragg, of the early days of X-ray diffraction. He told of how Laue's interest in the X-ray problem was aroused by a problem of Ewald's on the double refraction of light, and how Friedrich, somewhat against Sommerfeld's wishes (who thought that he should be getting on with other work), was persuaded, with the help of Knipping, to try the now famous experiment with a copper sulphate crystal. The various stages of the work were described in some detail, and Sir Lawrence mentioned that the early papers had recently been reprinted in *Die Naturwissenschaften* (16, 361; 1952). Sir Lawrence went on to describe the early work of his father and himself and to tell how he first hit upon the now famous idea of the 'reflexion' of a continuous spectrum (rather than one composed of discrete wave-lengths as Laue had supposed) by atomic planes, and the part played by the conception of a crystal lattice, which was then new to him. He outlined some of his early results on crystal structures and traced the development of X-ray spectroscopy by his father, following this by a mention of the early theoretical work of Darwin on the scattering of X-rays by perfect and imperfect crystals, which was so much in advance of experiment that it was overlooked and afterwards worked out in another form by Ewald. He ended by pointing out how many of the later developments had, in fact, been foreshadowed in the first three years.

Sir Lawrence was followed by Prof. von Laue, who spoke about his own experiences in those early days; this was not on the programme, and the pleased surprise of the audience was obvious. Speaking in German, apart from a few introductory remarks in English, he told of the first experiments in Munich and of his own contributions to the work, confessing that, like W. L. Bragg, he too was unfamiliar at the time with the conception of a crystal lattice. He characterized the German contribution as one concerned with 'principles' and the British as one concerned with 'models'. The former approach had been in danger of causing the subject of X-ray diffraction to run into a dead end, from which it had been saved by the latter; and Prof. von Laue pleaded for a collaboration between the two nations in political matters which should be as effective in the cause of peace as it had been in the cause of science. A summary of his remarks was then given in English by Dr. W. F. Berg.

After Sir Lawrence Bragg's historical review, and following Prof. von Laue's remarks, Prof. J. D. Bernal gave a talk in which, after some reminiscences of his own concerning his early days at the Royal Institution with Sir William Bragg, he discussed the future of X-ray crystal analysis in the light of recent developments. He showed how the real crystal, rather than the ideal, is becoming more and more the main object of study and forecast that we should, as a consequence, be led to a greater understanding of such phenomena as epitaxy, adsorption and catalysis, followed ultimately by an explanation of the phenomena of plastic deformation, creep, hardening and fatigue. Turning to methods of structure analysis, he hoped that the time would come when information justifiable on chemical grounds—the known mutual arrangement of constituent atoms in the structure, known ionic or atomic dimension, etc. —could be added to the X-ray data in a rigorous way. Prof. Bernal foresaw that, with the help of electronic and other computing machines, the heaviest part of crystal structure analysis would ultimately be automatic; he even foresaw that the reduction of observations might become so, the output being linked directly to the computer. But, as he said, we are still a long way from being able to drop a crystal down a hopper and receive a table of atomic coordinates or an electron density map within a short time.

The second session, on the morning of October 25, was devoted to 'review' papers on various present-day applications of X-rays, Dr. Dorothy Hodgkin dealing with chemical problems, Prof. G. V. Raynor with problems of the metallic state and Sir Lawrence Bragg with the application of X-rays to protein structure.

Dr. Hodgkin dealt mainly with recent developments in the analysis of organic structures and

[*] See "Forty Years of X-ray Diffraction", by Prof. J. M. Bijvoet, Prof. J. D. Bernal, Prof. A. L. Patterson and Sir Lawrence Bragg (*Nature*, 169, 949; 1952).

described, among other things, the way in which it is now possible, in certain instances, to determine the positions of hydrogen atoms. She then traced the way in which our knowledge of stereochemistry has been increased by our ability to study the effects of such factors as the repulsive forces between non-bonded atoms in addition to those of the classically directed valencies. Finally, she referred to the analysis of such complex compounds as vitamin $B_{12}$ and the problems set for the theoretical chemist by the molecular configurations recently found in substances such as the boron hydrides.

Prof. Raynor, after surveying the part played by the electron theory of metals in the development of our ideas of the metallic state, discussed Pauling's suggested valencies and described how, by making absolute measurements of X-ray scattering power, a check might be obtained on these. He added that such an attempt, recently made in Chicago, favoured, if anything, the conventional valencies. Other points dealt with by Prof. Raynor concerned the examination of the diffuse X-ray background, on one hand to determine the local distortions around dissolved atoms in alloys and, on the other, to measure the elastic constants of metals.

In the final talk of the conference, Sir Lawrence Bragg dealt with his recent work at Cambridge on hæmoglobins, carried out in collaboration with Dr. M. F. Perutz. He said that a systematic attempt is being made, based on an extensive series of intensity measurements of the diffraction by a hæmoglobin crystal at various stages of shrinkage, to see just how much could be discovered without making any structural assumptions; and he described a series of ingenious steps by which not only the size and shape of the protein molecule has been established, but from which also the distribution of scattering matter within the molecule is beginning to be understood. When it is realized that the volume of the molecule is 83,000 A.$^3$ dry and 116,000 A.$^3$ hydrated, the magnitude of this task will be appreciated; but Sir Lawrence gave every hope that, as he put it, we are now in sight of the promised land.

Space does not permit a detailed discussion of these or the previous papers, but a fuller report of the conference will appear in the *British Journal of Applied Physics*.

An account of the conference would be incomplete without a further reference to the dinner held on the evening of October 24, at which Prof. von Laue, replying to the toast of "X-ray Diffraction and the International Union of Crystallography", proposed by Sir Charles Darwin, made what is believed to be his first public speech in English. He began by referring to his early days in Strassburg and ended by hoping, as Röntgen had done before him, that, even if those younger workers present were not as lucky as he had been, they would derive as much enjoyment from their work as he had done from his. In a final gesture, he drank their health in a personal toast which was all the more appreciated for being so entirely and so obviously spontaneous.

In conclusion, a few words must be said about the historical exhibits at the Royal Institution which were shown during both days of the conference. Among other things on view were the original Bragg spectrometer, reproductions of Laue's original photographs, correspondence and note-books of the two Braggs, letters written by Barlow, Moseley and others, and even a (correct) model of rock salt constructed from balls of wool and knitting needles by Prof. Crum-Brown in Edinburgh in 1883. No one who attended the conference could fail to be impressed by the tremendous vitality of X-ray crystallography as well as by its versatility and power in application. He would indeed be a bold man who would guarantee what the next forty years of X-ray diffraction will bring forth.

J. Thewlis

# OBITUARIES

## Dr. C. H. Kellaway, F.R.S.

Charles Halliley Kellaway, director-in-chief of the Wellcome Research Institution, London, died on December 13 at the age of sixty-three. He was born in Victoria, and was educated at Melbourne Church of England Grammar School. A brilliant student, always the head of his year, he graduated at Melbourne in 1911, and after holding house appointments at Melbourne Hospital, became resident medical tutor at Trinity College, Melbourne, and then acting professor of anatomy at the University of Adelaide. During the First World War he served as a regimental medical officer with the 13th Australian Infantry Battalion in the Middle East and won the M.C. At the end of the War he worked at the Lister Institute in London under Dr. H. H. (now Sir Henry) Dale for a short period, and then became acting professor of physiology at Adelaide for a short time. In 1920 he was in England again as a Foulerton Scholar of the Royal Society. He worked at the National Institute for Medical Research and at University College Hospital, London. He returned to Australia as director of the Walter and Eliza Hall Institute, Melbourne, in 1923. During the Second World War he was director of pathology for the Australian Medical Services and later scientific liaison officer with D.G.A.M.S. In 1944 he retired with the rank of brigadier and became director-in-chief of research to the Wellcome Foundation, Ltd.

Kellaway's main interest in scientific work was initiated by his collaboration with Dale on the mechanism of anaphylaxis, and through most of his work he returned to the problem of cell damage and the associated release of histamine and similar substances. He was a pharmacologist working in the field of experimental pathology. The Hall Institute was closely connected with the Melbourne Hospital, to which Kellaway was appointed specialist physician, and consequently most of his research there was related with practical medicine. He worked on hydatid antigens and intradermal tests in the diagnosis of hydatid disease, on renal infection and hypertrophy. He studied intensively the pharmacology of the venom of the numerous Australian colubrid snakes, including many not previously studied, and extended his researches to the venom of spiders, the bee and the duck-billed platypus. He produced antivenoms in horses to several of the larger Australian snakes and collected venom from the snakes himself. In the course of this work he was once bitten by a tiger snake. His life was probably saved by the injection of antivenom; but he nearly died from serum reaction. He was one of the world's leading authorities on snake venoms. He continued his work on anaphylaxis and the histamine problem; one of his last personal investigations was conducted with collaborators on the pharmacological action of the toxins of the *Clostridium welchii* group, particularly in reference to the action on the pulmonary circulation. This was a good example of the application of physiological methods to experimental pathology; evidence was obtained that histamine, or a substance pharmacologically similar, was a link in the chain of action of the toxin.

Concurrently with all his personal research, Kellaway steadily developed the work of the staff of the Hall Institute. He had a gift for choosing able workers, and for fostering them. In the 'thirties, virus work was started under the present director, Sir Macfarlane Burnet; research on the *Q* fever virus is one of the outstanding examples of the growing importance of the Hall Institute. All the time Kellaway had considerable anxiety for the Institute on the financial side, for its original endowment was not large by modern standards; but by unceasing efforts he persuaded the Government, the Rockefeller Institute and other semi-official bodies and various private donors to increase the resources at his disposal, and before he left he had succeeded in getting erected for the Institute a beautiful modern building in close proximity to Melbourne Hospital. In addition to all this, with the growth of his personal reputation, his wise counsel was increasingly sought on pathological matters for the Government. He was, for example, appointed chairman of the commission which investigated the death of some children at Bundaberg from poisoning with the until then unknown staphylococcal toxin, which had developed in an accidentally contaminated injection of prophylactic.

Kellaway was elected a Fellow of the Royal College of Physicians in 1928, Foundation Fellow of the Royal Australasian College of Physicians in 1938 and Fellow of the Royal Society of London in 1940. He received the Walter Parfitt Prize of the Royal Society of New South Wales in 1932.

During the Second World War, the Hall Institute diverted its work into researches on influenza, scrub typhus, Asiatic schistosomiasis, blood typing and transfusion, drying of serum and other problems of direct importance in war; and in spite of his official duties with the Army, Kellaway continued to control its activities. When he accepted the post of director-in-chief of research to the Wellcome Foundation, Ltd., in 1944, he had the satisfaction of having brought the Hall Institute into the front rank of the world's medical institutes, and he had complete confidence that he was leaving the Institute to the care of an outstanding successor—one of his own men.

In the Wellcome Foundation, Kellaway was responsible for the research policy of the organization in Great Britain, and acted in an advisory capacity for the research activities of the American subsidiary company in Tuckahoe, U.S.A. He had under him the directors of the Wellcome Laboratories for Tropical Medicine, of the Research Laboratories at Beckenham and of the Museum of Medical Science and of the Museum and Library for the History of Medicine. While delegating much to his colleagues, as was inevitable, he kept very close interest in all their activities. He found time to serve on outside scientific committees, where he was often in demand because of his own reputation. His particular interest in the Foundation was the development of chemotherapeutic research; an intensive drive for the discovery of new compounds of therapeutic importance was started. What is perhaps the most important result so far is the drug sold as 'Daraprim', which seems likely to be of considerable importance as a suppressive drug for malaria. This came as a result of collaboration between the Foundation laboratories in Tuckahoe and London. It was Kellaway who first brought these laboratories to close collaboration.

The field in which he now worked was very different from that in which he had worked. But the way in which he adapted himself to his new responsibilities was a tribute to his wide knowledge and versatility, and he carried the organization successfully through some very trying times.

Kellaway was an attractive character. His boyish enthusiasm, his kindness to his colleagues and his discerning courtesy to his lowliest subordinate, combined with his resoluteness and reliability and his power to see another point of view, stirred affection and respect in all who worked with him. His courage in his last illness will be an abiding memory for those who witnessed it. Our sympathy goes out to his wife and three sons. J. W. TREVAN

---

We regret to announce the following deaths:

Prof. W. H. Hobbs, emeritus professor of geology in the University of Michigan, aged eighty-eight.

Prof. F. E. Weiss, F.R.S., emeritus professor of botany in the University of Manchester, on January 7, aged eighty-seven.

---

# NEWS and VIEWS

## Royal Astronomical Society: Awards

The following awards of medals have been made by the president and Council of the Royal Astronomical Society: *Gold Medal of the Society*: Prof. S. Chandrasekhar, for his contributions to mathematical astrophysics; *Eddington Medal*: Canon G. Lemaître, for his work on the expansion of the universe; *Jackson-Gwilt Medal and Gift*: Mr. J. P. M. Prentice, for his contributions to the study of meteors.

## Royal Photographic Society: Centenary Celebrations

On January 20 the Royal Photographic Society will celebrate the hundredth anniversary of its formation, and to mark the day there will be a special ceremony at 11 a.m. in the Society's house at 16 Princes Gate, London, S.W.7, when the president of the Society will receive the representatives of a large number of other societies and kindred organizations. At 3.30 p.m. in the house of the Royal Society of Arts in John Adam Street, London, W.C.2, exactly a hundred years later to the very hour and in the same place where the inaugural meeting of the Royal Photographic Society was held, Mr. Bertram Sinkinson, vice-president, will give a lecture entitled "The Centenary of the Royal Photographic Society", in which he will reconstruct the atmosphere surrounding the Society's inception and give historical details of the incidents which led to these events. Mention will be made of the great part played by the first officers of the Society, namely, Sir Charles Eastlake, president, and Roger Fenton, honorary secretary, and the support given to them by the many ardent pioneers of photography at that time, including

W. H. Fox Talbot. The main theme of the lecture will be based on two papers delivered at the first ordinary meeting of the Society, which were, in point of fact, pronouncements of policy: Sir William J. Newton delivered a paper on "Photography in an Artistic View and its Relation to the Arts", and Roger Fenton made pronouncements on "The Mode in which it is Advisable that the Society should conduct its Labours". After discussing the main principles of these two papers and illustrating, with the use of lantern slides, the effect they had on the later development of the Society, Mr. Sinkinson will explain how, during the past century, the early policies of the Society, mainly based on our artistic concepts, have been adapted to meet the growing ramifications of the photographic process as they are now applied in their many forms to the service of the community through the arts and sciences. Admission to this lecture will be by ticket, obtainable from the Secretary of the Society. Finally, in the evening of the same day the Society will hold a banquet at Claridge's Hotel, London, at which T.R.H. the Duke and Duchess of Gloucester will be the guests of honour; included among the guests will be the president of the Royal Society, the president of the Royal Academy of Arts, and the presidents or vice-presidents of twenty-seven other learned and cultural societies.

### Scientific Research in British Industries during 1951–52

FOR the Royal Society Empire Scientific Conference in 1946 there were prepared "Some Notes on Current Scientific Researches in the United Kingdom" which included, besides particulars of academic research at the universities, some notes on research in progress at the Royal Technical College, Glasgow, the College of Technology, Manchester, the Royal Botanic Gardens, Kew, the Rothamsted Experimental Station, the John Innes Horticultural Institution, the Wellcome Research Institution and some other research establishments directly attached to government departments. This list was appended to the Conference report and was later used as the basis for the first edition (1948) of the British Council's "Scientific Research in Britain". This was intended only for the use of the British Council; but, in view of the interest aroused and requests received for copies, it was arranged that the Department of Scientific and Industrial Research would sponsor future editions and that the British Council would collect the material. The edition for 1949–50 was entitled "Scientific Research in British Universities", the scope being limited to researches in British universities and university colleges; but neither this edition, nor the similar off-set litho edition for 1950–51, was made generally available. The report for 1951–52 is issued as an open publication on sale to the public (pp. 485; London: H.M.S.O., 1952; 8*s*. 6*d*. net).

The contents are arranged by universities and university colleges, and are classified by subjects under the laboratory or department concerned, with the name of the director of research or research worker. Work at colleges of technology is excluded, although the College of Technology, Manchester, appears under the Department of Technology, University of Manchester, and the inclusion of work of like standing in other major colleges of technolo would give the reader a more complete pict the lines of research being carried out in u

institutions throughout Great Britain. Only research which was pursued during the 1951–52 session and on which information has been published by the staff of the department within the past four years is included. An author index supplies information on the scientific activities of any particular research worker. The list constitutes a most useful reference volume for the industrial as well as the academic scientist and for libraries and information departments of research organizations.

### Technological Education in Great Britain

A REPORT on "A Policy for Technological Education", which has been issued by the Association of Scientific Workers, urges that, besides the creation of a technological university, it is necessary to extend further existing university departments of technology, particularly for students who have done two years of science, and to make more use of the existing technical colleges. For this purpose, the report considers that it is essential to place the financial responsibility of selected major technical colleges on a body of the standing of the University Grants Committee so that these colleges may become responsible degree-granting institutions, either through affiliation to universities or independently. Adequate facilities for research should be provided as well as further post-graduate courses and vacation courses, to facilitate contacts between industry and the universities. In making these recommendations, the report does not deal with the critical question of how many technical colleges should be developed in this way, nor in its recommendations for further financial assistance from the State to those technical colleges remaining under the financial jurisdiction of local authorities does it deal with the question of student numbers, either from the point of view of the number of technicians required or from that of the existence of students of the requisite intellectual capacity and other qualities. The recommendations for expansion here appear to assume that the supply of such students is unlimited. Stress is rightly laid on the provision of adequate maintenance grants for full-time students accepted in institutions of higher technology, but the content of higher technological education is briefly discussed without specific recommendation, other than the extension of the 'sandwich' type of full-time course and broadening the scientific basis of part-time courses, as well as extending them as far as possible.

### Bibliography of Science in Latin America

THE Centre of Scientific and Technical Documentation, an organization which, situated at Plaza de la Ciudadela 6, Mexico, D.F., was set up under the Unesco Programme of Technical Assistance, publishes monthly a *Bulletin* which contains translations int Spanish of the titles of all the original articles in th fifteen hundred scientific journals received regular in the Centre from all parts of the world. T arrangement is by broad subject and sub-divis within each subject, and then the listing is d alphabetically within each sub-division by the n of the first author. Papers published originall Latin America are specially with the September 1952 abstracts in French or papers.

The serie

Experts, held in Montevideo in 1948, and now two more volumes have been published: "Ecuador, No. 1" (pp. 74, 1952), and "Argentina, No. 3" (pp. 150, 1952). In these two volumes, which are published by the Unesco Centre of Scientific Co-operation for Latin America, Montevideo, the usual practice is followed of including first a list of institutions, indicating their scope and resources and giving the names of their chief officials, and then an alphabetical list of scientific workers, in which the publications and field of work of each worker are listed. Further volumes are promised for Argentina.

## Study of Psychology in the United States

A study of the development and status of research and education in psychology in the United States is being undertaken by the American Psychological Association and will be conducted in two parts: one part will be an evaluation of the status of psychological knowledge; and the other an analysis of occupational, educational and institutional relations of scientific psychology. The study will include a survey of methodology, theory and applications of psychology to determine the interrelationships among various branches of psychology and the importance of psychology to other scientific fields. Problems in psychological education, man-power, research support, communications and administration will also be examined. The project, which will cost about 40,000 dollars, derives its financial support from the National Science Foundation as another in the series of studies of specific fields of science which will assist the Foundation in developing a national science policy in the United States.

## Declassified Information on Atomic Energy Piles

A revised edition of a report from the Atomic Energy Research Establishment, Harwell, entitled "A Quantitative Study of Uranium-Graphite Lattices" (*R/R 922*; pp. 28+12 pl. London: H.M.S.O., 1952; 6*s*. net), by Profs. E. A. Guggenheim and M. H. L. Pryce, which was first issued on August 11, 1945, has recently been declassified and published. Calculations and results are given concerning piles of natural uranium rods arranged as a lattice in graphite. The quantity of uranium required for the pile to react steadily, the reproduction constant $k$, the square of the migration length $M^2$, and the Laplacian $(k - 1)/M^2$ are particular quantities specified. The calculations show the effect of varying the radius $a$ of the uranium rods and the radius $b$ of the moderator cell. Both $k$ and the Laplacian each have a maximum, while the critical mass of uranium has a minimum. For a cylindrical pile with height equal to diameter, composed of uranium rods sheathed in 1·15 mm. of luminium, arranged as a lattice in a graphite noderator and surrounded by a graphite reflector, e minimum quantity of uranium required is given 26 tons. In this case $a = 1{\cdot}25 \pm 0{\cdot}10$ cm., $= 11{\cdot}5 \pm 0{\cdot}50$ cm., and the width of the air-gap rounding each rod $= 1{\cdot}5 \pm 0{\cdot}25$ cm. The effect arying the air-gap is considerable, and the reasons this are discussed. In a homogeneous pile the proportion of uranium to to remain approximately $b$ and the air-gap. The hree diagrams illus- tribution

Rennie. Interested readers may well like to refer also to another A.E.R.E. report (*R/L 5*) by C. A. Rennie, entitled "Lecture Notes on Pile Theory" (*R/L 5*; pp. 29+3 pl. London: H.M.S.O., 1952; 5*s*. net), in which the basic nuclear design features of natural-uranium graphite-moderated thermal reactors are dealt with. This report includes references to published papers containing fuller treatment.

## Stomatal Behaviour in the Onion

Since the stomatal guard cells in the onion (*Allium cepa*) contain neither chloroplasts nor any visible quantity of starch, but do respond to changes in light intensity (which cannot be attributed to concomitant changes in temperature, etc.), the classical explanation of stomatal movement in terms of the starch $\rightleftarrows$ sugar mechanism cannot apply. Whether the hydrolysis of a soluble polysaccharide is involved has not yet been investigated. This interesting case of stomatal behaviour has recently been investigated by O. V. S. Heath (*New Phytol.*, 51, No. 1, 30; 1952), who has advanced various hypotheses to account for effects observed during the course of the relevant experiments.

## Conference on Plant and Animal Breeding

A one-day conference on "Plant and Animal Breeding" will be held under the auspices of the Joint Biology Committee and the Association of Agriculture at University College, London, on March 7. Mr. Alexander Hay, general secretary of the Association of Agriculture, will take the chair, and the speakers in the morning session will be Prof. L. S. Penrose, Galton professor of eugenics in University College, London, whose subject will be "Present-day Human Genetics", and Dr. Arthur Walton, deputy director of the Agricultural Research Council Unit of Animal Reproduction, Cambridge. The latter, in a talk entitled "Animal Genetics", will deal with the improvement of farm animals through modern breeding methods. In the afternoon Mr. W. B. Barker, of King's School, Wimbledon, will speak on "Teaching Genetics in School", and the conference will close with an address on "Plant Breeding Genetics" by Dr. G. D. H. Bell, director of the Plant Breeding Institute, Cambridge, who will describe the application of Mendelian principles to the work of increasing food production through crop improvement. The fee for the conference is 5*s*., and application should be made as early as possible to the Secretary, Joint Biology Committee, c/o British Social Biology Council, Tavistock House South, Tavistock Square, London, W.C.1.

## Discussion on Collagen

An informal discussion on the "Nature and Structure of Collagen", under the auspices of the Colloid and Biophysics Committee of the Faraday Society, will be held in the Wheatstone Physics Laboratory, King's College, London, W.C.2, during March 26–27. It is hoped that the response will be such as to allow for a small number of papers on the biological background to the subject, although the chief emphasis on this occasion will be given to physical and chemical studies of native and extracted or precipitated collagens. The biochemical studies of the amino-acid and polysaccharide contents of collagens of various origins now in progress in various oratories are essential to the understanding of obtained by means of the techniques of fraction, electron microscopy, and infra-red dichroism. It is hoped that researches in these fields will be reviewed and form the basis for discussion of models of the structure of collagenous fibres. Those wishing to attend or to take part in the discussion should communicate with Prof. J. T. Randall, King's College, London, W.C.2, as soon as possible.

## Medical Research Awards for Study Outside Britain

THE Medical Research Council is offering a number of fellowships and scholarships as follows: *Rockefeller* travelling fellowships (2,600 dollars a year or 3,600 dollars for married men) for graduates resident in Great Britain with previous research experience in medicine, to work at a centre in the United States or elsewhere abroad before taking up positions for higher teaching or research in Great Britain; *Eli Lilly* travelling fellowships of a similar nature to the Rockefeller awards; *Dorothy Temple Cross* research fellowships in tuberculosis (£650 a year or £900 for married men) for British subjects to devote themselves to the advancement of knowledge of tuberculosis at a centre outside Britain; *Alexander Pigott Wernher Memorial* travelling fellowships in ophthalmology and otology (£650 a year or £900 for married men) for suitably qualified medical graduates to study at a centre abroad before taking up positions for higher teaching or research in these subjects; and *French Government* exchange scholarships (45,000–90,000 francs a month, plus a marriage allowance payable in sterling) for young British graduates in medicine or science who have had some experience in a branch of medical science, to work in a research institution in France on some branch of medical science other than clinical medicine. All the above awards carry travelling allowances and other allowances, in addition to the stipend. Applications for the Rockefeller, Lilly and Cross fellowships must be received not later than March 15, and for the Wernher fellowships and French Government scholarships not later than March 31. Application forms and all further particulars can be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, London, S.W.1.

## Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: C. W. Benson (administrative officer, Nyasaland), biologist, Department of Game, Tsetse Control, Northern Rhodesia; M. D. Ashwin and T. G. Gudgeon (agricultural assistants, Nyasaland), agricultural officers, Nyasaland; J. R. Curry (senior agricultural officer, Federation of Malaya), chief field officer, Agricultural Department, Federation of Malaya; D. L. Downie (botanist, Uganda), tea research officer, Nyasaland; L. J. S. Littlejohn (agricultural officer, Tanganyika), chief soil conservation officer, Tanganyika; A. K. F. Nicol (assistant conservator of forests, Nigeria), chief conservator of forests, Sierra Leone; I. P. Tamworth (forestry officer, Hong Kong), assistant conservator of forests, Federation of Malaya; E. H. Jaques (senior geologist, Aden), geologist, Federation of Malaya; C. S. Cree (senior assistant conservator of forests, Northern Rhodesia), conservator of forests, British Honduras; D. B. Fanshawe (deputy conservator of forests, British Guiana), principal scientific officer (forestry research officer), Northern Rhodesia; J. W. Macaulay (senior veterinary research officer, Northern Rhodesia), senior veterinary research officer, Kenya; K. M. Francis (government statistician, Sierra Leone), government statistician, Gold Coast;
D. P. E. Speldewinde (sub-assistant conser
forests, Federation of Malaya), assistant con
of forests, Federation of Malaya; H. D
agricultural officer, Gambia; E. B. Dennison
Pickering, R. B. Skinner and D. J. Wheele
cultural officers, Nigeria; A. V. Haddon
Tuley, botanists (plant breeders), Federat
Malaya; M. G. Hawson and M. J. Strickland
cultural officers, Federation of Malaya;
Howston, plant breeder, Tanganyika; A. D. F
agricultural officer, Uganda; D. C. Mackenz
F. P. Massey, agricultural officers, Sierra
H. J. McLean, agricultural officer, Tanga
A. R. McWalter, soil chemist, Federation of
A. B. Rains, pasture research officer, Nigeria
Hockey and H. J. Richards, geologists,
W. C. White, geologist, Somaliland Prote
W. Jackson, scientific officer, Sierra Leone
Stanton, senior scientific officer, Nigeria
Adlard and R. J. McEwan, assistant conser
forests, Nyasaland; D. K. Bailey, geologist,
Rhodesia; P. B. H. Bailey, geologist, Britis
P. R. Browning, statistician, East Africa H
mission; R. D. T. E. Chandler, chemist, F
of Malaya; Prince John Loewenstein, c
anthropology, Raffles Museum, Singapor
Stratton, statistical officer, Gold Coast; R.
biochemist, Federation of Malaya.

## Announcements

H.R.H. THE DUKE OF EDINBURGH h
election to honorary membership of the I
Metallurgists.

# RESEARCH IN BRITISH COLONIAL TERRITORIES

"COLONIAL RESEARCH 1951–1952"* follows the form of last year's report. Besides the brief report of the Colonial Research Council, to which are appended a list of schemes approved for research grants, April 1, 1951–March 31, 1952, and the report of the Director of the Colonial Products Advisory Bureau for 1951–52, it comprises the ninth annual report of the Colonial Products Research Council, the eighth annual report of the Colonial Social Science Research Council, the seventh annual reports of the Colonial Medical Research Committee and the Committee for Colonial Agricultural, Animal Health and Forestry Research, the fifth annual reports of the Colonial Insecticides and the Colonial Economic Research Committee and annual reports of the Colonial Fisheries Advisory Committee on Fisheries Research, of the Director of the Anti-Locust Research Centre on Locust Research and Control, and of the Tsetse Fly and Trypanosomiasis Committee: lists of publications are appended to the several reports. The Colonial Research Council's report is, as usual, confined to matters not covered by the specialist committees, and its most important feature is the warning it sounds as to the effects of the uncertainty regarding the provision of Colonial Development and Welfare funds after the present Acts expire in March 1956. As the Council here points out, such uncertainty both makes the planning of long-term research impossible and is also hindering the recruitment of research workers for the Colonial territories.

The Council's reasonable request for an early clarification of the position is one which should receive prompt response from the Government, and should be carefully noted by scientific workers as well as by the Parliamentary and Scientific Committee. Little is said in these reports about other difficulties in recruiting scientific workers; seventeen research appointments were made during the year, and about forty officers in some ninety posts in the Colonial Agricultural, Veterinary and Medical Services have been declared suitable for transfer to the Colonial Research Service. The Council in this report stresses the importance both of direct contact between research organizations and institutions in Great Britain and the Colonial territories, and of visits of members of the various research advisory committees to the territories where the schemes sponsored by the committees operate.

As was forecast in last year's report, there was a substantial reduction in the number and size of research schemes made during the year: some thirty-six new schemes and fifty-three supplementary schemes, involving grants totalling £868,851, brought the total allotted to Colonial Development and Welfare Schemes to a net expenditure and commitment of £10,140,000 at March 31, 1952, of which £9·94 millions is chargeable against funds provided under the 1945 and 1950 Acts. Additional assistance provided by Colonial Governments or industry since 1940 is estimated at about £3 millions. Of the gross allocation of £11,100,000, about 32·7 per cent has been for agricultural, animal health and forestry schemes, 13·9 per cent for medical research, 13·8 per cent for fisheries research, 11·7 per cent for tsetse and trypanosomiasis research, 8·8 per cent for social science and economic research, 6·2 per cent for insecticides research, 4·6 per cent for research sponsored by the Colonial Products Research Council and 3·5 per cent for anti-locust research. About 39·0 per cent of the gross allocation has been for schemes to benefit the East African territories, 18·3 per cent for the West African group, 11·1 per cent for the South-East Asian territories and Hong Kong, 8·7 per cent for the West Indian Colonies, British Guiana and British Honduras and 6·2 per cent for the Central African territories (Northern Rhodesia and Nyasaland). Schemes approved during the year besides those recently noted (cf. *Nature*, 170, 311; 1952) include £28,750 for the Anti-Locust Research Centre and its extra-mural research, £31,500 for physiological and biochemical research at Makerere College, Uganda, £26,620 for the East African Agriculture and Forestry Research Organization, £24,403 for the Nutrition Field Station, Fajara, Gambia, and £17,500 to enable clove research in Zanzibar to be extended until August 31, 1953.

Work under four of the Economic Co-operation Administration projects mentioned in last year's report was started or continued in 1951–52. An American plant-breeder visited Nigeria to investigate the breeding of improved grain sorghums and maize, and an entomologist was secured for research in Northern Rhodesia into the control of ticks affecting livestock. The African Studies Branch of the Colonial Office is undertaking surveys of particular subjects to meet current Colonial Office needs, and a complete survey of the development of local government in the African territories since 1947 began to appear as supplements to the *Journal of African Administration* in January 1952. Mr. Ian Small, the newly appointed director of the West African Building Research Organization, was proceeding to the Gold Coast in the summer of 1952, and Mr. G. A. Atkinson, the Colonial building research liaison officer, who has now visited twenty-five Colonial territories, visited Hong Kong and the South-East Asian territories and also Aden and Cyprus during January–May 1952. His report on his visit to the Caribbean area was presented during the year, and a review of aided self-help housing, based on information gained during the tour, was circulated to all Colonial governments. Mr. Atkinson reached the conclusion that little or no organized scientific research into building problems is possible in the area in the immediate future. Much could be done, however, to improve building materials by making technical information more readily available and by providing better facilities for training building technicians and for testing materials.

Publication of Volume 3 of the "Demographic Survey of the British Colonial Empire" is expected early in 1953. Censuses were taken during the year in North Borneo and Gambia and, for the non-African population and for Africans in employment, in Northern Rhodesia. The Directorate of Colonial (Geodetic and Topographic) Surveys moved into new headquarters at Tolworth in June 1951; but little progress is reported in recruiting field-survey staff. A chain of triangles has been reconnoitred, beaconed and observed from Eastern Uganda (near Mount Elgon) down the east side of Lake Victoria to Tanganyika. Most of the southern half of Basutoland has been covered with secondary triangulation. An additional twenty geologists were appointed during the year, and the strength of the overseas scientific staff was 180 in 1951, compared with 58 in 1947, although there is still a shortage of experienced geologists trained in mapping, petrology and mineralogy. The total area geologically mapped during the year increased considerably. Research continues at various institutions in the United Kingdom on the economic production of Columbian minerals, iron ore and apatite from the soils surrounding the Sukulu carbonatite ring-structure in Uganda. Good progress is being made in the examination of coalfields in Tanganyika, and the report welcomes the growing practical interest of the universities in Great Britain in Colonial geology.

* Colonial Office. Colonial Research 1951–1952: Reports of the Colonial Research Council, Colonial Products Research Council, Colonial Social Science Research Council, Colonial Medical Research Committee, Committee for Colonial Agricultural, Animal Health and Forestry Research, Colonial Insecticides Committee, Colonial Economic Research Committee, Tsetse Fly and Trypanosomiasis Research Committee, Colonial Fisheries Advisory Committee, Director of Anti-Locust Research Centre. (Cmd. 8665.) Pp. ii+253. (London: H.M. Stationery Office, 1952.) 6s. 6d. net.

Investigations undertaken in Uganda by the British Paper and Board Industry Research Association on the suitability of local fibres for incorporation in a pulp for the manufacture of a kraft-type of paper for containers have given promising results, and a paper entitled "Some Notes on the Durability of Paint in Tropical Climates" has been prepared, with particular reference to the humid climate of Singapore. Progress continued in the installation of *radio-sonde*/radar wind stations for the study of upper-wind conditions, and regular observations to a height of 60,000 ft. are now made by stations established at Aden, Gibraltar, Lagos, Malta and Nairobi. In the oceanographic research to which the Colonial Office contributes, some new instruments are being developed, including a simple method of recording the changes in depth of a mid-water trawl, by measuring the changes in pressure in a rubber bag attached to the trawl, and connected to the ship by a reinforced hose-pipe. Discovery by the R.R.S. *William Scoresby* of the breeding ground of the pilchard (*Sardinops sagax*) enabled detailed information to be supplied to Colonial fishery officers in West Africa. The work of the Colonial Liaison Officer at the Road Research Laboratory in Britain is attracting increasing attention from Colonial engineers, and a report is being prepared on his visit in October and November 1951 to Northern Rhodesia and Nyasaland, where the same road problems, broadly speaking, were met as in East and West Africa, though the soils appear to present less difficulty than in East Africa. It is proposed to place the work of the Colonial Products Advisory Bureau, which covers much the same field as that of the Colonial Products Research Council, under a common directorship with the latter body early in 1953. During 1951–52 the Bureau has carried out work on the chromatographic separation of the active principles of pyrethrum, on distilled lime oil from Zanzibar, gum arabic from Tanganyika and the Somaliland Protectorate, cattle hides from East and West Africa, the drying of goat skins, the utilization of *Brachystegia* wood from Tanganyika for paper-making, and the tanning properties of the barks of *Eucalyptus robusta* and *E. saligna* from Uganda.

The ninth annual report of the Colonial Produc
Research Council stresses the value of the work
the Colonial Microbiological Research Institute a
of the work carried out there on the fermentation
the cocoa bean. The results already obtained
likely to prove of immediate value to plant-breed
as they enable commercial evaluation to be mad
small samples of beans. A provisional patent

function of irreversible hydrolytic scission of the branch links in amylopectin. The *Z*-enzyme is a β-glucosidase, and with its aid it has been found that amylase contains branch linkages. The *Q*-enzyme has been recognized as a transglucosidase. An excellent oil has been extracted from the eighteen tons of heat-dried oil-seeds of *Tetracarpidium conophorum* received from Nigeria and is now being distributed in the paint industry for technical evaluation. Progress is reported in the study of the germination factor of *Striga*, and highly satisfactory results were obtained in Nigeria with a new machine for harvesting *Hibiscus cannabinus*, and accordingly further trials are being made with jute in British Guiana.

The eighth annual report of the Colonial Social Science Research Council refers to the great restraint which the Council has had to exercise in making new grants. Since October 1, 1951, the Council has had to operate within a limit of £325,000 until March 31, 1956, and on March 31, 1952, only some £200,000 was uncommitted. Accordingly, it was necessary to refuse applications for new grants which were not already receiving considerable financial support from other sources. Although the recruitment position for experienced research staff improved, difficulty is still being encountered in recruiting senior staff capable of organizing research, and in such special categories as demography and law. Much of the present report is occupied by a retrospect of the work of the Council since 1945, and there are appended to it annual reports for 1951–52 from the East African Institute of Social Research, Makerere College, the West African Institute of Social and Economic Research, Ibadan, the Rhodes–Livingstone Institute, and the Institute of Social and Economic Research, University College of the West Indies, as well as a list of publications by research workers assisted by the Council.

Commenting on the progress of Colonial studies in British universities, the Council refers to the work of the Department of Anthropology in the University of Manchester, which is closely associated with the work of the Rhodes–Livingstone Institute on Central African Studies, the work on race relations carried out under the auspices of the Department of Anthropology in the University of Edinburgh, and to the analysis of the social organization and types of society in the highlands of New Guinea and the studies of the appearance of cargo cults in the Pacific Islands and of the Pacific islander in commerce and industry being carried out by the Department of Anthropology of the Australian National University. The Survey of African Marriage and Family Life has been completed and is now in the press. Other reports in the press are Mr. J. N. D. Anderson's synoptic survey of the present position of Islamic law in the British African territories and Aden, Prof. C. M. Dohe's study of the Bantu languages of Southern Africa and the West Indian volume of the late Dr. Kuczynski's "Demographic Survey of the British Colonial Empire", while numerous other investigations are being prepared for publication. The East African Institute of Social Research has completed a survey of the European, Indian and African inhabitants of Jinja township and continued village surveys of immigrant labour in Buganda. A study of the present method of selection and training of African leaders in East Africa is proposed, as well as a survey of the Indian community in and around Kampala. At the West African Institute of Social and Economic Research, the inquiry into the Nigerian monetary and banking system is being completed and also that into Yoruba social and economic organizations. Definite proposals have been made regarding the functions of the Institute in relation to the Nigeria produce-marketing boards. The major event at the Rhodes–Livingstone Institute was the appearance of its first major publication, "Seven Tribes of British Central Africa". The Institute of Social and Economic Research, Jamaica, reports progress in the projects for the preparation of national income estimates, the determination of the trend in consumption patterns in Barbados and on experiences of management in the adaptation and training of Jamaican industrial workers.

(*To be continued*)

---

# INDUSTRIAL RADIOLOGY GROUP OF THE INSTITUTE OF PHYSICS

## MEETING IN SHEFFIELD

THE summer meeting of the Industrial Radiology Group of the Institute of Physics was held at Crewe Hall, Sheffield, during July 3–5. The success of the meeting was in no small way due to J. F. Hinsley and H. S. Peiser, who were responsible for the local arrangements, and to the staffs at Crewe Hall and at the various companies and institutions visited.

A day and a half were devoted to lectures, the opening session on "Training in Industrial Radiology" being given in two parts, the first by Mr. J. C. Rockley, of the Aeronautical Inspection Directorate, Harefield, and the second by Mr. J. D. Hislop, of Solus-Schall, Ltd. Mr. Rockley pleaded for a longer training course than is at present available for industry, with a recognized award, and spoke of what is being done by the exploratory committee of the City and Guilds of London Institute, to which the Institute of Physics has made recommendations.

Mr. Hislop thought that the maximum tuition in the time available in a part-time course can only be given if a good deal of this is devoted to theoretical work. In dealing with the special problems of weld examination, he put forward a plea for standards of interpretation which could be incorporated in any final training scheme and stressed the importance of correct identification and of orderly reporting. He thought that the training of a radiographer is essentially a long-term one, and suggested that managerial staff should become more familiar with the limitations of the method.

The first paper during the afternoon was given by Dr. R. Jackson, of the British Coal Utilization Research Association, on "The Presentation of Results in Radiography with Special Reference to the Terminology of Casting Defects". Dr. Jackson stressed the need for as good a radiograph as could be obtained, followed by careful interpretation, with as full information about the casting as possible in advance. He concluded with a description of the many difficulties which had been met in drawing up the proposed British Standards Institution terminology.

The second afternoon paper had the title "Economic Aspects and Administration of an Industrial Radiology Department", and was a joint paper by E. W. Colbeck, F. Cousans, H. S. Peiser and J. R. Rait (all of Hadfields, Ltd.). Mr. Peiser, who delivered the lecture, dealt particularly with radiography in the laboratory of a steelworks. Radiography, he said, could be divided into three groups, namely, inspection, *ad hoc* problems, and investigations of manufacturing techniques. In the first, 100 per cent inspection is only justified if failure in service would cause destruction of a valuable engineering unit or endanger life. The chief economic considerations involved were briefly discussed. In dealing with *ad hoc* problems on which the X-ray department has come to the aid of the foundry, Mr. Peiser mentioned the determination in weld repairs of the extent of the defect and the quality of the repair when it has been made, and problems arising in the examination of inaccessible plant or equipment. In dealing with the investigation of manufacturing techniques, he said that this type of investigation is the most valuable economically and, in addition, from it better products usually result; he gave as an example from the hundreds undertaken the elimination of shrinkage cavities. Mr. Peiser concluded with some remarks on the economic operation of a radiographic department.

On the evening of July 3, Dr. O. Vaupel, of the Rontgenstelle, Material Prüfungsamt, Berlin, lectured on the subject of "The Standardization of Radiology in Germany". Dealing specially with X-ray and gamma-ray techniques, he said that new quality standards for X-ray and gamma-ray pictures would be published shortly under standard *DIN* 54110, which would replace the present standard *DIN* 1914. Dr. Vaupel next described the wire penetrameter, consisting of wires of the appropriate material embedded in thin rubber, four gauges being required to cover thicknesses up to 3¼ in. Since none of the orthodox types of penetrameter is capable of showing up small differences in defect sensitivity because the gaps (for example, between adjacent wires) were too wide, E. A. W. Müller in 1942 invented a more accurate penetrameter known as the 'bacillæ test', an ingenious device in which short lengths of randomly distributed wires are contained in nine boxes embedded in low-adsorption material, the whole containing thirty-one wires of the same diameter, for example, 0·4 mm. The observer draws the positions of the wires as seen on the film and compares the result with their true positions. This is repeated for wires of different diameter, and the number of observed wires is plotted against the diameter, extrapolation giving the diameter necessary for thirty-one wires. On the subject of the standardization of magnetic crack testing, Dr. Vaupel said that the importance of this method can be judged from the fact that in 1944 there were in Germany as many magnetic crack detectors in use as X-ray equipments. The methods by which magnetism is induced in the specimen had been standardized as well as the direction of the resultant magnetism. There is also a standard test for magnetic inks. Dr. Vaupel also described the Berthold magnetic penetrameter which indicates the efficiency of a magnetic test.

The first paper at the morning session of July 4 was read by Mr. J. F. Hinsley, of Edgar Allen and Co., Ltd., and had the title "The Radiography of Castings". Starting with a review of the casting processes, the subsequent chain of events in the foundry was described. To talk with the foundryman the radiographer needs to understand his terms, and these were explained. The design of castings was next discussed, in particular the formation of defects during the solidification process, and it was shown how the radiologist can help in this connexion, as also in the feeding process.

The last lecture, on July 4, was given by Mr. G. T Harris, of William Jessop and Sons, Ltd., who spoke on "Non-Destructive Testing in a Steelworks", which for the purpose of his talk he divided into three sections, namely, identification, checking mechanical and physical properties, and the detection of surface and internal defects. In the first section can be placed the spectrograph and its simplification, the spark test with a grinding wheel; microhardness testers and thermo- and tribo-electric methods were also described. In the second section Mr. Harris spoke of automatic thickness gauges and then described the core loss comparator, in which, by placing a coil round the bar under test and measuring the core loss, quality differences are at once obvious. In discussing magnetic crack detection, the effect of the direction of the field was shown. Inspection by penetrating oil has been improved by using fluorescent oils, and an American method called 'Dy-chek' was referred to. Another method has the advantage of using a water-soluble oil which is easily removed. Electrolytic etching is widely used, said Mr. Harris, as it is a very sensitive method of detecting surface cracks. He discussed the correlation of the results of ultrasonic flaw detection and radiology, and stated that it is difficult to estimate the size of a defect by the ultrasonic method, though he thought that automatic scanning would be an advantage. Speaking of radiology, Mr. Harris said that developments needed are X-ray equipments able to penetrate ten inches of steel, scanning of large specimens by counters, Xero-radiography and the amplification of fluorescent images by image converters.

B. N. CLACK

# MECHANISM OF PHOTOGRAPHIC SENSITIVITY IN SILVER BROMIDE

IT has been shown recently by Loening[1] that pure silver bromide in the form of an aqueous sol has only a very slight sensitivity to light as judged after development. Sensitization can be achieved by adding silver ions or gelatine or substances such as sodium nitrite to the sol. Ordinary photographic emulsions have already the sensitivity conferred by gelatine, and there are three well-established methods[2] of obtaining further gains of sensitivity, depending on the addition of one of three substances: reducing agents, gold salts and sulphur compounds. These substances probably react with the silver bromide to form minute quantities of silver, gold and silver sulphide respectively at the grain surfaces: at any rate, that is the simplest supposition. All this refers to 'chemical' sensitization, as distinct from extension of spectral sensitivity by dyes.

According to the theory of the photolysis of silver bromide put forward in 1938 by Gurney and Mott[3], the absorption of a light quantum by silver bromide removes an electron from a bromide ion, leaving a 'positive hole'. The electron and the hole should both be highly mobile. If silver particles are present, they become negatively charged by trapping electrons and grow by attracting the mobile interstitial silver ions that are naturally present in the crystal (Frenkel disorder). This theory still holds the field, more recent attempts based on the assumption of Schottky disorder having now been abandoned[4]. As applied

o the formation of latent images, however, the theory
incomplete: one has to explain how the positive
les are prevented from recombining with the
trons and how the first electrons are trapped if
ver is initially present. What is lacking is
y a theory of sensitization, and the question
o the sensitizers mentioned function as
es, or positive hole traps, or both?

e given on November 20 before the
and Technical Group of the Royal Photo-
ic Society, Dr. J. W. Mitchell described a
ies of elegant experiments on the point carried
out by himself and collaborators in the University of Bristol. The complications of photographic emulsion work were avoided by using pure dry monocrystalline plates of silver bromide and applying the sensitizer (silver, gold or a metallic sulphide) directly in a very thin uniform surface-layer by vacuum evaporation. The plates were about 1 cm. square and 0·01 cm. thick, with the crystallographic [100] axis approximately perpendicular to the square face. An ordinary metol-hydroquinone developer was used, with a little gelatine added to prevent excessive fog. Unexposed unsensitized specimens gave only a slight irreducible fog in the form of small oriented silver crystals scattered over the surface, as observed in previous single-crystal work by Dankov[5] and Boissonnas[6]. Exposure to light produced no further developable effect, even when sufficient to produce visible (internal) separation of silver. A developable latent image was produced, however, by exposure under a solution containing a bromine acceptor.

By means of slits and masks, the deposition of sensitizing substances and the exposure to light were restricted to well-defined circular or rectangular areas of the specimen. Areas bearing $10^{15}$ silver atoms per sq. cm. (about one monolayer) were blackened by development without exposure, the edges appearing well defined. Specimens bearing $10^{14}$ silver atoms per sq. cm. gave only the normal irreducible fog without exposure, but were blackened in certain areas by development after exposure—that is, they were sensitized but not fogged by the deposited silver. This blackening or latent-image formation was expected to occur only in the areas both silvered and exposed to light, but the result was quite different. The blackening appeared only in the unexposed areas, and spread beyond the silvered areas, the spreading being greater at a greater distance from the exposed area: with sufficient exposure the entire unexposed area became blackened. Essentially the same phenomena were observed with gold and with arsenious, antimony and thallous sulphides (silver sulphide, not being stable enough for evaporation, was not tried).

If the sensitizers in these experiments acted mainly as electron traps, the blackening would presumably have been confined to the sensitized areas. It seems that the phenomena can only be explained by supposing that they act as positive-hole traps, that is, they react with the bromine, which is quite reasonable from a chemical point of view. If some of the bromine is removed in this way, a surplus of electrons remains, and apparently no special electron traps are then needed to ensure the formation of latent-image silver specks, for the latent image appears mainly on the naked silver bromide surface. The mobility of the electron being about twice that of the positive hole explains why the image is produced far from the exposed area, in which a surplus of positive holes will be left. The space charge produced by the electrons
travelling faster than the holes would proc
urging interstitial silver ions into the el
regions. Dr. Mitchell did not, however,
give a complete theory of the phenomena.

It appears then that silver, gold an
sulphides all sensitize by the same mecha
the function of each is to react with ha
that no special electron traps are needed
tivity. In the case of silver sensitization, t
of positive holes by the silver permits the
of new silver elsewhere by the electrons
stitial ions, and one might say that in
latent image is formed by redistributing
initially present. These tentative conclusio
they may not be directly applicable to the
tion of ordinary emulsions, are of obvious

of any growing tree (apart from certain exceptions such as trees less than a given diameter, garden and orchard trees and a licence-free allowance of 825 cu. ft. per quarter) unless a licence has been granted by the Commissioners.

Apart from the Forestry Commissioners and the staff of the Forest Department proper, there are no less than three National Committees (England, Scotland and Wales), eleven Regional Advisory Committees (five for England, four for Scotland and two for Wales) and a Home Grown Advisory Committee—a total of fifteen committees to assist in carrying out the forestry work of a comparatively small island.

One important provision of the Act is that the Commissioners have now the power to add replanting of the area to a felling licence. By establishing the principle that it is contrary to the public interest that forest land should be cleared and then allowed to lie derelict, the Act will check the further accumulation of unproductive woodland areas.

The area of forest planted during the year was 57,164 acres, of which 17,491 were in England, 26,960 in Scotland and 12,713 in Wales. The total area of land acquired during the year was 113,200 acres, of which 56,000 were classed as plantable. Of the latter, 16,000 were in England, 33,000 in Scotland and 7,000 in Wales.

It is estimated that private owners planted 12,300 acres, of which 6,300 acres were planted with the aid of grants. Under the dedication scheme deeds were completed with seventy-nine owners in respect of 37,010 acres of woodland. The planting and maintenance grants have been revised and increased. During the quinquennium a total area of 138,000 acres of the woods planted since 1921 has been thinned, and it is estimated that during the same period 38 million cu. ft. of poles and timber (roughly a million trees) have been extracted from these new public forests, and a small return on the capital outlay is being obtained.

An additional national forest park, named Loch Ard, was set up in the lovely Trossachs district of the Scottish Highlands. This must be one of the most beautiful of all the national forest parks so far established.

E. P. Stebbing

# COMMONWEALTH OBSERVATORY, CANBERRA

## REPORT FOR 1951

THE report of the Commonwealth Astronomer for the year 1951[*] covers the activity of the Commonwealth Observatory, Canberra, during the twelve months up to December 31, 1951. During this period sunspot sketches were obtained on 294 days, and solar radio-noise observations on a frequency of 200 Mc./s. were continued. Transit observations with the small reversible transit instrument gave 251 determinations of clock error obtained on 216 nights. Random errors from the sidereal pendulum clock have been eliminated by determining the error directly of one of the mean-time quartz-crystal clocks. Time services were originated four times each day, and some preliminary work has been carried out with the view of supplying a time service for South Australia.

Dr. G. E. Kron, of the Lick Observatory, assisted by Dr. S. C. B. Gascoigne, using the Reynolds 30-in. reflector, carried out a programme of red and infrared measurements, utilizing a refrigerated caesium oxide cell, and determined the magnitudes at effective wave-lengths 8250 A. and 6300 A. of stars in standard regions *D*2, *C*4, *C*6, *D*6, *C*8, *D*10, *C*12; of all nearer stars within about 12 parsecs (and this part of the programme included accurate photometric observations of Proxima Centauri); and of certain bright stars included in previous Mt. Stromlo programmes. In addition to this, they worked for eighteen nights on various objects in the Magellanic Cloud, using a refrigerated 1P21 multiplier. The magnitude limit was about 15·5, and all nine Cepheids examined were appreciably bluer than galactic Cepheids of similar period. Dr. O. J. Eggen, using an 1P21 multiplier on the Oddie telescope, measured colours and magnitudes of stars of known parallax brighter than photographic magnitude 11·0 and also of Cepheids brighter than magnitude 10·0. Objects of some interest were also observed, and *HD*223045 showed a light variation of 0·75 mag. with a period of only 80 min.

The contractors for the 74-in. reflector informed the director of the Commonwealth Observatory that the mounting was ready for dispatch from London, where it had been on exhibition during the Festival of Britain, and the mirror, which has been lightly polished, shows a good figure. Notable progress has been made with the building for the 50-in. (the old Melbourne 48-in.) reflector, and the mirror, by the firm of Cox, Hargreaves and Thomson, has arrived in Canberra. It is proposed that this instrument be initially set up in a Schmidt–Gregorian form prior to the completion of the Schmidt correcting plate and the construction of the plate-holder and tube for the Schmidt telescope. A 40-in. aluminizing tank is in use, and all the larger astronomical mirrors have been coated with aluminium.

The issue of regular monthly publications of the Ionospheric Prediction Service has been maintained. In addition to the analysis of data from Macquarie Island, some results have been obtained from the Townsville Station, which has been re-occupied. The new building for the Hobart Station has been completed, and power lines and aerials were in course of erection. Attempts are being made, in collaboration with the Overseas Telecommunications Commission, to re-introduce the system of storm warnings.

A supplement to the report for 1950[*], which marks the twenty-fifth anniversary of the commencement of the observational work of the Commonwealth Observatory, takes the form of a history of the Observatory to the end of 1950. Originally known as the Commonwealth Solar Observatory, which started on January 1, 1924, with the appointment of Dr. W. G. Duffield as first director, actual observations commenced at Canberra in the following year and at Mt. Stromlo in 1926. The history of the foundation extends back nearly twenty years from the latter date, and the details connected with this are very fully set out in the supplement in a review of about seven thousand words. At the end of this there are several illustrations and photographs, the former showing various details of the Observatory, and the latter giving general views of the Observatory, of the Reynolds 30-in. reflector arranged for photoelectric work, and of a corner of the machine shop. This supplement forms very interesting reading.

# FORMS OF INSECTICIDE-RESISTANCE IN HOUSEFLIES AND BODY LICE

By Dr. J. R. BUSVINE

London School of Hygiene and Tropical Medicine

## Investigations with Houseflies (*Musca domestica*)

In 1951, I described the distinctive characters of two laboratory strains of insecticide-resistant houseflies, originally obtained from Italy and Sardinia[1]. These have provided the material for some attempts to segregate, by selective breeding, different kinds of resistance which may occur in houseflies. Batches of flies in successive generations were exposed to various insecticides (by the methods described in 1951) and the lines maintained from survivors. The numbers exposed in each generation were about twenty-five unmated of each sex or forty to fifty fertilized females; and the aim was to adjust the dose to obtain a kill of 80–90 per cent. Owing to the rather small numbers available, failure to increase the resistance of a sub-colony may sometimes have been due to the chance absence of particular genes from the population sample chosen. Therefore, while a positive result was of interest, a negative one was of dubious significance.

The results of check tests, done at intervals of weeks, and sometimes months, showed that, in the absence of selection, the various strains and sub-colonies maintained their particular characteristics over many generations with little change.

The original strains were: an Italian colony (*I*), a Sardinian one (*S*) and a non-resistant colony (*N*). The lines selected from them were as follows:

(1) *Sub-colony* (*N* × *S*). Susceptible flies were crossed with those of the *S* strain and the progeny selected for resistance to γBHC. The surviving males were back-crossed with susceptible females and the progeny again selected for resistance to γBHC. This was repeated twice more with the following results. Selection with γBHC had maintained γBHC-resistance in the strain, together with some tolerance of chlordane and dieldrin; while the repeated back-crossing with susceptibles had lowered DDT-resistance practically to normal.

(2) *Sub-colony* (*Ch*). A line derived from the *I*-strain was selected for resistance to chlordane on six occasions over a period of eleven generations. There was an enormous rise in resistance to chlordane (× 500), to dieldrin (× 300) and to γBHC (× 60) with only a small increase in resistance to DDT (× 2·2).

(3) *Sub-colony* (*P*). An attempt was made to increase resistance to pyrethrins in a sub-colony of the *I*-strain. Batches were exposed to partially lethal concentrations on seven occasions over a period of twelve generations, with only a slight increase in resistance (× 1·3). Afterwards, flies of this sub-colony were twice selected for resistance to paralysis by DDT; this had the incidental effect of somewhat augmenting resistance to pyrethrins.

(4) *Sub-colony* (*SS*). Some flies derived from the *S* strain were selected for resistance to kill by DDT in two successive generations. This was in order to raise the average lethal dose to a level comparable with that of the *Ch* sub-colony.

(5) *Sub-colony* (*S.k-d*). My colleague, Dr. C. M. Harrison, kindly allowed me to use some flies of a sub-colony which she has been selecting for resistance to DDT-paralysis. This colony was derived from the *S* strain and selected over eleven successive generations by breeding from flies not readily knocked-down by DDT. The result of this selection (which will be reported more fully elsewhere) was highly successful.

*Investigation of selected strains.* After the selection procedures described, the various sub-colonies were maintained in isolation without further treatment. Their levels of resistance to a variety of insecticides were measured, and the results are set out in the accompanying table from which the following conclusions may be drawn:

(1) Resistance to BHC and chlordane in the housefly seems to be quite independent of DDT-tolerance; changes in resistance to the first two do not affect the level of the latter, and vice versa. On the other hand, the factors for resistance to BHC, chlordane and dieldrin are linked together, so that selection for one of them raises the resistance to the others. Possibly a single defence mechanism copes with a range of these chlorinated compounds.

(2) Resistance to the paralysis caused by DDT is not rigidly linked with resistance to its lethal effect. These factors are experimentally difficult to separate, because one cannot select for knock-down without killing some of the flies. However, it will be seen that strains *I* and *S* have about the same levels of resistance to the lethal action of DDT and so have strains *Ch* and *SS*; but the members of each pair differ considerably in resistance to paralysis.

(3) Something must now be said about the compound described as 'DANP' in the table, which is 1,1-dianisyl-neopentane. The preparation and properties of this compound have been described by Brown and Rogers[2], of the Merck Company, U.S.A., to whom I am indebted for supplying a sample. This compound is similar to DDT, but contains no chlorine; it has the *p*-chlorine atoms replaced by methoxy groups and the —CCl$_3$ group changed to —C(CH$_3$)$_3$. Therefore it cannot be degraded by dehydrochlorination to the non-insecticidal ethylenic body; which process appears to be one type of protective mechanism in DDT-resistant houseflies.

On inspection of the results in the table, it will be seen that resistance to paralysis by DDT is correlated with resistance to dianisyl-neopentane and to

Resistance characteristics of certain strains of houseflies ('DANP' is dianisyl-n entane; see text)

| Strain | Derived from | Med. leth. conc. (%) DDT | Knock-down by DDT (%) | | Medium lethal concentrations (%) | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | | ½ hr. | 1 hr. | 'DANP' | Pyrethrin | γBHC | Dieldrin | Chlordane |
| *N* | Rome | 0·07 | 95 | 100 | 0·90 | 0·07 | 0·006 | 0·006 | 0·04 |
| *N.S* | *N* × *S* | 0·08 | 96 | 100 | 0·75 | 0·08 | 0·06 | 0·1 | 0·6 |
| *S* | Sardinia | 1·8 | 88 | 100 | 0·65 | 0·06 | 0·05 | 0·3 | 2·8 |
| *I* | Italy | 1·7 | 30 | 50 | — | 0·35 | 0·005 | 0·007 | 0·038 |
| *SS* | *S* | 3·7 | 66 | 93 | 1·1 | 0·10 | — | — | — |
| *Ch* | *I* | 3·8 | 50 | 50 | 6 | 0·22 | 0·3 | >1·8 | 20 |
| *P* | *I* | 5 | 17 | 20 | 7 | 0·6 | 0·006 | 0·004 | 0·05 |
| *S.k-d* | *S* | >5 | 0 | 0 | >10 | 0·8 | 0·03 | 0·22 | 1 |

pyrethrins. This is an extension of my 1951 observations that the paralysis-resistant strain *I*, which was also resistant to pyrethrins, was indifferent to the ease of dehydrochlorination of DDT analogues; thus contrasting with strain *S*. It seems clear that there is a DDT-resistance factor not concerned with dehydrochlorination, and it appears that this factor is associated with resistance to DDT-paralysis and kill by pyrethrins.

## DDT-resistant Body Lice

The report of DDT-resistance in Korean body lice[3] re-awakened our interest in alternative insecticides for control measures. Body lice are unpleasant to rear continuously, and we had allowed our culture at the London School of Hygiene and Tropical Medicine to lapse. Some difficulty was experienced in obtaining a new colony, until Dr. S. Madwar kindly sent some eggs by air from a strain kept at the laboratory of the Insect Control Section of the Ministry of Public Health, Cairo. This strain was maintained and expanded here and was used for testing new synthetic insecticides.

Results of comparative tests, however, suggested that these lice possessed undue resistance to DDT. Thus, spray tests indicated a median lethal concentration nine times as high as that obtained with the same technique in 1946[4] using susceptible British lice, whereas the dose for γ-benzene hexachloride was only 1·3 times as great. To confirm the earlier observations, another susceptible colony was started, from an infested man in London, and tested side by side with the Egyptian lice.

A range of new insecticides was then tested against the new DDT-resistant strain. Batches of the lice were exposed for a standard period (18-hr.) at 30° C. on filter papers impregnated with 3 mgm. per sq. cm. of oil solutions of different concentrations. From the resulting mortalities, median lethal concentrations were determined as follows: DDT $>$ 3 per cent (susceptible lice 0·6 per cent); γBHC 0·025 per cent; chlordane 0·12 per cent; dieldrin 0·018 per cent; aldrin 0·04 per cent; toxaphene 0·6 per cent; allethrin 0·74 per cent; pyrethrins 0·14 per cent.

From these figures, it appears that lice of this colony are normally susceptible to insecticides other than DDT. Tests with dianisyl-neopentane gave a median lethal concentration of 2·5 per cent for the susceptible colony, whereas none of the Egyptian colony was killed by 10 per cent. Therefore, the resistance cannot be accounted for by a dehydrochlorination mechanism.

*Origin of the resistant strain.* Insecticide-resistant strains of pests are usually 'developed' by widespread use of a particular insecticide, which kills off the susceptible individuals and allows the resistant ones to proliferate. A possible reason for the DDT-resistance of the strain from Cairo is that the Egyptian Ministry of Public Health had undertaken vigorous campaigns of DDT-dusting of villagers in all districts for four years (1946–50) before the colony was started in the Cairo laboratory. Afterwards the lice were reared for two years in the absence of insecticide before the sub-colony was sent to me.

It is not possible to compare with precision the DDT-resistance of these lice with those in Korea without a detailed knowledge of the technique used by the American workers. However, it appears that the Korean lice were more resistant, because they were stated to pass their complete life-cycle on cloth impregnated with 0·1 per cent DDT in acetone. Fifty first-stage nymphs of the Cairo strain were placed on tape impregnated with this solution, and most of them died within five days, all being dead within twelve days.

*Acknowledgements.* I am grateful to Dr. C. M. Harrison for allowing me to experiment with flies from one of her cultures; and also to Dr. A. A. Shwarby for helping me to obtain and rear the lice from Cairo.

# PERMEABILITY OF INSECT CUTICLE TO AQUEOUS STAINS AND VULNERABILITY TO INSECTICIDES

By S. MUKERJI and S. N. CHATTERJEE

Indian Agricultural Research Institute, New Delhi

WIGGLESWORTH[1] showed that abrasion of the surface of the cuticle of an insect by inert dusts not only increases the permeability to water but also facilitates the entry of insecticides. Later[2], he showed, by the use of ammoniacal silver hydroxide, that the abrasion of the protective wax layer in beetles takes place chiefly at the points of articulation of the limbs but also, to some extent, at other points where the soft cuticle of the moving insect is rubbed against the dust or where the dusts get into the mobile joints. More recently, Slifer[3] used aqueous solutions of dyes (methylene blue, neutral red, fast green and crystal violet) to find out worn and abraded areas of the cuticle on the ventral walking surface of the legs, namely, the tarsus and pretarsus with their appendages. Slifer's studies in this direction indicated that the under-surface of the arolia of *Melanoplus differentialis* (Thomas) lacked the protective cement layer which elsewhere on the leg protects the waterproof waxy film present in the outermost layers of the cuticle. She thus concludes that, because of the absence of the cement layer, the wax on the ventral surface of the arolium is easily dissolved by wax solvents and the inner layers which remain then offer little resistance to the penetration of dyes and other substances. Slifer's observations thus lend support to the experimental results with insecticides made by Kennedy, Ainsworth and Toms[4]. By staining, with iodine, various parts of the body of *Locusta migratoria migratorioides* R. & F., Slifer[5] afterwards obtained results which indicated a similar absence of the cement layer from other cuticular areas besides the arolia. So far, nothing is known about work on similar lines on other insects.

Using the cuticle as a whole of insects of different orders collected from Nature as well as bred in the laboratory, and following Slifer's technique, the reaction of aqueous solutions of various dyes was observed with the view of locating the areas permeable to stain which would, at the same time, react positively to an aqueous solution or wettable powder of some well-known insecticides. Thus, the use of a carrier oil was altogether avoided, so as to ascertain the degree of permeability of the aqueous solution or

* The fluid was absorbed in this region rapidly

suspension, as the case may be, of the toxic materials in a localized zone and their subsequent transference to the vital epidermal cells. Although different stain reactions were obtained with various types of insects, only the results of those which were tested with insecticides have been incorporated in the accompanying table. Of the four stains used, crystal violet was found to be the most penetrating reagent as it is most fat-soluble; a 0·1 per cent aqueous solution of this stain was therefore used as final indicator. In the case of *Schistocerca gregaria* Forsk., both freshly emerged (moulted forms) or older nymphs and adults were used, and there was but little difference in the reaction to stain or insecticide in the same stage of the insects tested. Older adults were, however, found to be comparatively more resistant to BHC. The wettable powder was applied to the parts with a positive stain reaction with a very fine brush and allowed to dry on the spot.

The results so far obtained indicate that for each type of insect the vulnerable areas react differently to different types of toxic materials used, that is to say, they are selective for positive reactions for different insecticides. The reaction is therefore dependent on the various physical properties of the insecticides involved, as well as on the morphological and chemical character of the cuticular components. The results further establish the fact that besides the areas of natural abrasion, which one of us (S. M.) is tempted to name 'ecoabrasion', other selective vulnerable areas are also present on the insect cuticle through which the absorption of a fatal dosage of the toxic materials in aqueous media may occur. Preliminary experiments indicate that in the case of the tarsi (with appendages) of freshly moulted adults, kept under conditions where there was least chance of abrasion, a high percentage of mortality was noticed after the superficial application of wettable BHC, whereas no death was observed when the compound was applied to the pretarsi.

Further work on this subject is in progress.

We are indebted to Prof. V. B. Wigglesworth (Cambridge) and Dr. E. H. Slifer (Iowa), respectively, for valuable advice. [April 18.

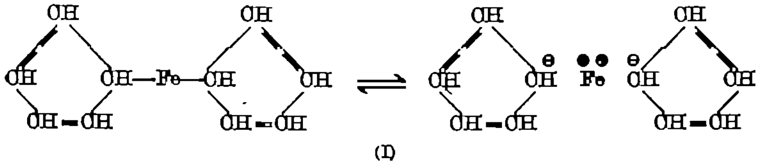
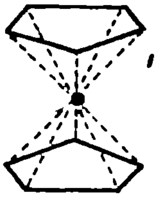
## *Bis*-cyclopentadienyl Iron: a Molecular Sandwich

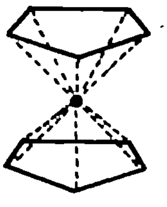
Kealy and Pauson[1] have described the preparation of *bis-cyclo*pentadienyl iron, $(C_5H_5)_2Fe$, which they formulated as (I). More recently, Wilkinson, Rosenblum, Whiting and Woodward[2] have observed that the compound is diamagnetic, that it has zero dipole moment, and that only one C—H stretching frequency occurs (at $3{\cdot}25\,\mu$) in the infra-red absorption spectrum; on the basis of these observations they have proposed the very unorthodox structures (II) or (III). In the present communication we wish to present X-ray evidence for the correctness of (II) and also to interpret this unusual structure in terms of electronic structural principles.



(I)



(II)



(III)

*Bis-cyclo*pentadienyl iron crystallizes from common organic solvents in a variety of forms, needles elongated along [110] and diamond-shaped plates bounded by {110} and {001} occurring the most frequently. The unit cell is monoclinic with cell dimensions, $a = 10{\cdot}50$ A., $b = 7{\cdot}63$ A., $c = 5{\cdot}95$ A., $\beta = 121°$, space-group $P2_1/a$ ($C^5_{2h}$), and contains two formula units of $C_{10}H_{10}Fe$. Each molecule must therefore possess a centre of symmetry occupied by the iron atom, which contributes either $+\,2f_{Fe}$ or zero to the structure factors according as $h + k$ is even or odd, so that the preliminary structure analysis may be carried out in a direct fashion.

The main features of the structure are apparent from the initial projections of the electron density on the (010) and (001) crystal planes. The function $\rho(xz)$ computed with all signs positive is shown in Fig. 1. Four of the five atoms in each *cyclo*pentadienyl unit are resolved, the fifth being obscured by the heavy iron peak at the origin. For $\rho(xy)$, all terms with $h + k = 2n$ have been taken as positive; of the other terms, only two, $F(210)$ and $F(120)$, are of any considerable magnitude and, since $F(110)$ is strong and necessarily positive, it follows from the relationship[3], $s(h) = s(h')s(h + h')$, that these two terms must have the same sign, which may be taken arbitrarily as either positive or negative. The function $\rho(xy)$ is shown in Fig. 2. The plane of the *cyclo*pentadienyl ring is almost normal to the projection plane and the individual atoms are not resolved; but the general shape of the molecule is fairly obvious.

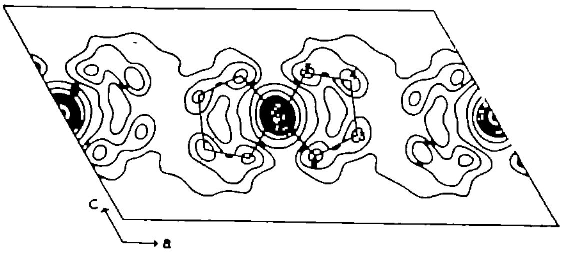


Fig. 1. Plot of function $\rho(xz)$. Contour lines are drawn at equal arbitrary intervals except for the iron atom, where the intervals have been increased by a factor of four for the sake of clarity

The two projections, considered together, leave no doubt that the 'sandwich' structure (II) proposed by Woodward *et al.* is correct. It is not yet possible to derive accurate details of the molecular dimensions and only a rough description can be provided at present. A molecular centre of symmetry is imposed by the space-group restrictions; but the appearance of the projections is reasonably consistent with a much higher molecular symmetry, $D_{5d}(\bar{5}m)$. Within rather wide limits of error, the C—C distance is about $1{\cdot}4$ A. and the C—Fe distance about $2{\cdot}0$ A.

A simple ten-bonded structure for $(C_5H_5)_2Fe$ is excluded, since only eighteen potentially bonding electrons are available and since, further, the set of iron orbitals of the correct symmetry cannot be formed using only *s*, *p* and *d* orbitals. A plausible formulation involving the resonance of a smaller number of bonds among the ten positions might be possible; but we have preferred to use molecular orbital theory.

The set of *d*-orbitals transforms in the group $D_{5d} = C_{5v} \times i$, according to the following scheme: $d_{z^2} \sim A_{1g}$, $d_{xz}, d_{yz} \sim E_{1g}$; $d_{x^2-y^2}, d_{xy} \sim E_{2g}$. The $\pi$-orbitals of the *cyclo*pentadienyl radical, according to simple molecular orbital theory, are $A_1$, $E_1$ and $E_2$ in order of decreasing stability. For two *cyclo*pentadienyl radicals oriented as in this molecule, each pair of orbitals can combine to give two orbitals transforming as even (gerade) or odd (ungerade) representations, for example, $2A_1 \rightarrow A_{1g} + A_{1u}$.

We assume that in the molecule the pair of *cyclo*pentadienyl radicals has the configuration

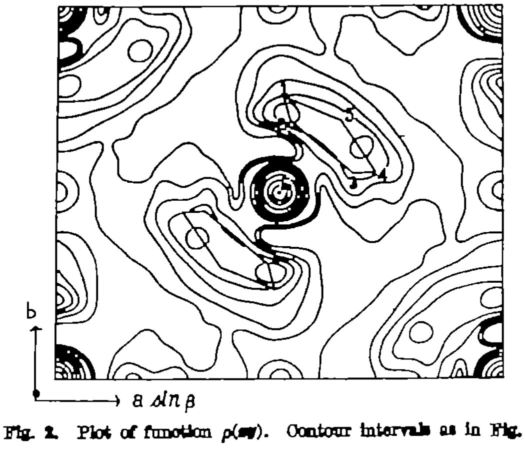

Fig. 2. Plot of function $\rho(xy)$. Contour intervals as in Fig. 1

$(A_{1g})^2(A_{1u})^2(E_{1g})^2(E_{1u})^4(E_{2g})^0(E_{2u})^0$ and the iron atom the configuration $(A_{1g})^2(E_{1g})^2(E_{2g})^4$. It will be seen that formally we may form two 'covalent-ionic' bonds using the $E_{1g}$ orbitals on the two parts of the molecule and also two 'donor' bonds in which the $E_{2g}$ electrons of the iron atom are able to spread into the empty $E_{2g}$ *cyclo*pentadienyl orbitals. (Although the σ-orbitals of the pair of *cyclo*pentadienyl radicals transform in the same way as the π-orbitals, they will not contribute to the bonding, since (1) the bonding orbitals are fully occupied and too strongly bound to lose electrons to the iron atom, and (2) the antibonding orbitals will be much less stable than the empty π-orbitals and hence will not behave as acceptors in the formation of 'donor' bonds.) The diamagnetism of the compound follows from the coupling of the four previously uncoupled $E_{1g}$ electrons.

The *cyclo*pentadienyl radicals will presumably acquire a negative charge as a net result of the two types of bond formation. The numerical value of the bond energy and the extent of the charge transferred cannot be calculated by methods at present available. We can, however, make some predictions as to the stability of *bis-cyclo*pentadienyl compounds of the other transition metals. Manganese and chromium, with sufficient donor and acceptor orbitals available, should form compounds of the same order of stability as that of iron. The cation $[(C_5H_5)_2Fe]^+$, which has been isolated as the tetrachlorogallate and picrate[2], is exactly analogous to the manganese compound. Nickel, with the configuration $(3d)^{10}$, has no orbital available for covalent bonding, while cobalt has only one orbital available. In both cases, therefore, we expect the compound to be much less stable than that of iron. Another possible stable compound, however, is the cation $[(C_5H_5)_2Co]^+$, in spite of the instability of the corresponding cobaltous complex.

Work is being continued with the view of obtaining a more precise description of this unusual molecule. We should like to thank Dr. H. M. E. Cardwell for preparing a sample of *bis-cyclo*pentadienyl iron for us.

## Daily Variation of Meson Intensity and its Possible Solar Origin

THE variation of meson intensity with solar time has been studied at Ahmedabad (mag. lat. 13° N., altitude 50 m.) and at Kodaikanal (mag. lat. 1° N., altitude 2,343 m.) with vertical triple-coincidence Geiger counter telescopes of narrow aperture with 11 cm. of lead. Observations at Ahmedabad with two similar independent telescopes extend over a period of two years, while at Kodaikanal with four independent telescopes they extend over a period of five months. Elaborate precautions were taken to keep experimental conditions very constant, and the results of independent but simultaneously operated telescopes at each place were similar. The intensity at each place was determined from hourly photographs of the mechanical recorders. For the purpose of the solar daily variation, the bi-hourly values of intensity were considered.

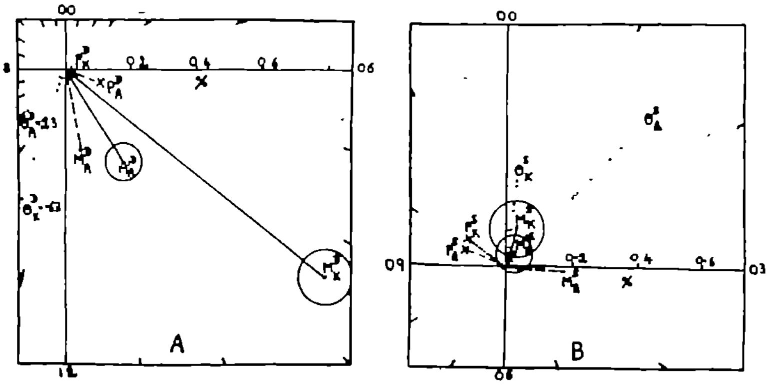
The solar daily variation of meson intensity is predominantly diurnal at Kodaikanal with an amplitude of 1·1 per cent. At Ahmedabad it has an amplitude of only 0·4 per cent with an important semidiurnal component as well. Figs. *A* and *B* show on 24-hr. and 12-hr. harmonic dials respectively the diurnal and semidiurnal harmonic components of the meson intensity $M_A$ and $M_K$, the atmospheric pressure $P_A$ and $P_K$ and the ground temperature $\theta_A$ and $\theta_K$ at Ahmedabad and Kodaikanal. The diurnal and semidiurnal components are indicated by the additional suffixes *D* and *S* respectively.

At low latitudes the periodic daily variations of *P* and θ are larger and more pronounced than the irregular day-to-day variations which are so marked at places in high latitudes. Also, at low latitudes the daily variation of atmospheric pressure is mainly semidiurnal and that of temperature is diurnal. As a result, the semidiurnal components $P_A{}^S$ and $P_K{}^S$ are predominant, whereas $\theta_A{}^S$ and $\theta_K{}^S$ are negligible. This fortunately provides a means of studying the effect of pressure on meson intensity independently of other meteorological factors. At Ahmedabad, $M_A{}^S$ and $P_A{}^S$ have a very high correlation of − 0·96, the pressure coefficient being − 1·7 per cent per cm. mercury, in agreement with the mass absorption coefficient for mesons observed by other workers from day-to-day variations of intensity. At Kodaikanal, on the other hand, this correlation is only + 0·29. As, however, $M_K{}^S$ itself is only 0·12 per cent in amplitude and is not significant, this positive value might be fortuitous. The absence of the usual mass absorption coefficient indicates that during the atmospheric oscillations at Kodaikanal opposing factors act on *M*, and mask this absorption effect. These could be changes in heights of levels of meson formation or perhaps a density effect near these levels. An interesting feature of the present results is that, even near the equator for a high-level station, there is no marked semidiurnal variation of meson intensity positively correlated with pressure.

The atmospheric pressure plays an important part in the solar daily variation of mesons at the low-level station at Ahmedabad, but produces a negligible effect at Kodaikanal. The correlations of $M_K$ with $\theta_K$ and of the pressure-corrected meson variation $M'_A$ with $\theta_A$ are negligible. Ground temperature has therefore negligible effect at both places.

The curve of the residual meson variation corrected for pressure at Ahmedabad and the meson variation curve at Kodaikanal are both significant and strikingly similar. Both are diurnal with amplitude $M'_A = 0{\cdot}33 \pm 0{\cdot}06$ per cent and $M_K = 1{\cdot}1 \pm 0{\cdot}08$ per cent with maxima at 0950 and 0840 hr. local time respectively. It is unlikely that these variations are caused by a positive temperature effect such as is found by Duperier from day-to-day variations of mesons. Apart from the maxima being much earlier than the time at which a maximum of temperature in the upper atmosphere would be expected to occur, the amplitude of the diurnal temperature variation at the 200-mb. level is, on existing meteorological evidence, totally insufficient to account for a variation of meson intensity of 1·1 per cent as found at Kodaikanal. Variations of geomagnetic field are also not capable of explaining this variation.

There are thus grounds for believing that the observed diurnal variation of *M* is caused by an anisotropy of the primaries and is therefore extra-terrestrial in origin. The greatly reduced amplitude as well as a shift of maximum towards later hours at Ahmedabad when compared with Kodaikanal appears to be connected with the change of altitude between the stations. This is also seen in the ionization chamber results obtained at Huancayo as compared to the lower-level stations operated by the Carnegie Institution[1]. The amplitude of variation observed with our narrow-aperture Geiger counter-telescopes is larger than the omnidirectional ionization chamber results, as is to be expected. The increase of the percentage amplitude with elevation suggests the contribution of a larger number of low-energy particles which can make their effect felt at a high-level station but not at a sea-level station.



Amplitudes and hours of maxima in local time of harmonic components of meson intensity, atmospheric pressure and ground temperature variations. (*A*) 24-hr. harmonic dial; (*B*) 12-hr. harmonic dial

Since the variation is believed to be extra-terrestrial in origin, and the hour of maximum occurs at about the same local time during daylight hours throughout the year, a solar origin of this variation is suspected. The possibility of a part of the cosmic radiation originating from the sun, as deduced here from the nature of the residual diurnal variation of mesons, is supported by the occasional large increases in cosmic-ray intensity associated with solar flares, by recent observations associating variations of cosmic-ray neutrons with solar prominences, and by the large diurnal variation of the star intensity in the upper atmosphere reported by Lord and Schein[2]. Riddiford and Butler[3] have recently described processes by which particles from the sun can be accelerated to cosmic-ray energies. A close study of the occurrence of the hour of maximum under different conditions of observation of cosmic-ray intensity would throw a great deal of additional light on this subject. We hope to present shortly more data concerning this.

We are indebted to the Atomic Energy Commission of India for supporting this project. We are grateful to Prof. K. R. Ramanathan for many valuable discussions, particularly concerning the meteorological aspects of the problem.

## Improved α-Track Autoradiographs of Biological Specimens

THE use of Eastman Kodak nuclear track plates, type *NTA*, in the autoradiographic study of tissue containing thorotrast has been described previously[1]. Autoradiographs of this type are made as a matter of routine by floating a paraffined tissue section on to a photographic plate. However, during the floating and subsequent contact with wet emulsion, some of the radioactive material is leached out. Moreover, the large opaque clumps of thorium deposits in the tissue make counting of α-tracks in the underlying emulsion difficult.

The difficulties can be surmounted when liquid emulsion is poured over the section. This technique has been applied by Leblond and co-workers[2] and further improved by Bélanger[3], who described the 'inverted autograph' in which the tissue–emulsion complex is inverted and stained after processing. The 'inverted autograph' is of great advantage in the work with transparent sections, but observation of an autograph through tissue containing opaque substance is unsatisfactory. An attempt was therefore made to repeat the inversion process prior to final mounting for microscopic inspection.

The Ilford *G 5* emulsion which is available in the gel form was applied. The conditions adopted were as follows: the emulsion was liquefied at 42° C. and poured over the deparaffined section on a prepared glass slide at approximately 40° C. The emulsion was dried by means of an air stream and stored in a 5-cm. lead shield inside the refrigerator. The *G 5* emulsion was processed with an amidol developer and required an acetic acid stop-bath prior to fixing. When fixation was almost concluded, hardener was added. Inversion was done after washing, and the tissue–emulsion complex was allowed to dry on the new slide before staining. Since staining involves re-swelling and subsequent drying, an effort must be made to keep the emulsion from wrinkling. It was found advantageous to cut off excess emulsion at a distance of a few millimetres from the edge of the tissue section immediately before re-inversion. The difficulties in obtaining a plane tissue–emulsion complex which will adhere smoothly to a glass slide after re-inversion were minimized when the thickness of the processed emulsion was well below 100 microns. Since the maximum range in emulsion of the α-particles from thorium and its decay products is about 45 microns, the emulsion layer need not be thicker than that range.

The re-inverted autoradiographs give a clear picture of the distribution of the α-emitter in the tissue. Counting and topographic co-ordination of tracks with their points of origin in the tissue is extremely easy, even where large clumps of deposits are present in the tissue. Leaching of the radioactive material during the histological fixation of the tissue cannot be avoided completely; but, with proper precautions, contamination by dissolved and redistributed radioactive material becomes negligible. Therefore, in this case, the method of freeze-drying offers little advantage.

The diffusion of thoron out of the section and into the emulsion during exposure manifests itself more strikingly in the poured *G 5* emulsion than in the *NTA* plate. The emulsion over the tissue contains a multitude of thoron stars and, due to the favourable geometrical conditions, the probability for all four-prongs of the thoron stars being visible is very high. Also, the associated β-particles show in the *G 5* emulsion as tracks. Storage of the plates in a lead shield reduces the accumulation of electron background tracks considerably (about a factor of 50 after a 10-day exposure).

Experiments are in progress in which the same technique is being applied to tissue containing beta emitters.

This investigation was supported by the James Picker Foundation on the recommendation of the Committee on Radiology, National Research Council.

*Note added in proof :* Since this communication was submitted, a letter by Prof. L. F. Bélanger upon the subject and dated July 15 has been published in *Nature* of October 11, p. 625.

## Abnormalities in the Ionosphere at High Latitudes

THE object of this communication is to direct attention to some interesting features of the incidence of the abnormal ionization in the *E*- and *D*-regions of the ionosphere at high latitudes during periods of magnetic disturbance[1,2].

For convenience, we select for study types of storm disturbance which are easily identified in the tables of data circulated by ionospheric observatories: (*a*) Storm *E*, the dense form of abnormal *E* which is totally reflecting on frequencies high compared with the *E* critical frequency (for example, present above 6 Mc./s. or preventing observation of the *F2* critical frequency); (*b*) storm *D*, the intense *D*-region ionization which attenuates high-frequency waves so that they cannot be received at vertical incidence on any frequency.

The variations of the frequency of occurrence of these phenomena with time and position are readily evaluated and are found to have very interesting properties. The polar region may be divided into three zones, in each of which the incidence of the phenomena varies in a fairly regular manner. The most important zone may be called the 'storm belt'. In this the disturbances are particularly frequent and intense and show very regular and coherent variations with longitude. This zone overlaps, but is probably not identical with, the zone of maximum auroral activity. The number and intensity of the *E*- and *D*-region disturbances decrease rapidly with distance outside the storm belt but are otherwise similar to those found in the nearest sections of the belt. In the 'polar zone', the diurnal variations of both phenomena are radically different from those found elsewhere, but are modified locally by the activity in the storm belt. It is interesting to note that the characteristics of the fluctuations in the *F2*-region are also anomalous in this zone.

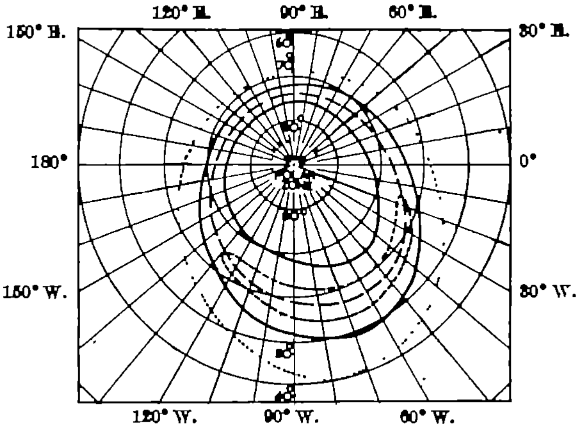

Fig. 1. Approximate position of main arctic zones: ———, boundaries of storm belt; - - - -, boundaries of abnormally intensely disturbed part of storm belt; — —, approximate position of maximum activity; ......, outer boundary of polar quiet zone

The diurnal variation of the storm *E* at all stations in the storm belt is very large. Thus, for example, over Canada about 80 per cent of the occurrences are found between 2000 and 0200 L.M.T., and less than 5 per cent between 0800 and 1600 L.M.T. The local time at which the diurnal maximum probability of occurrence is found is almost independent of longitude, changing from about 2100 L.M.T. in Sweden to 2300 L.M.T. in Canada. Thus the ionization behaves, approximately, as if it were generated in the classical manner by a stream of charged particles entering the ionosphere at a fairly constant angle relative to the direction of the sun. The diurnal maximum probability of occurrence of storm *E*, however, varies very greatly with longitude, reaching a large maximum near and over Canada. This change is particularly great for the most dense forms of storm *E* ionization which are practically confined to a sub-zone centred near Canada (Fig. 1).

The storm *D* ionization in the storm belt has quite different characteristics. The diurnal variation is less than that for storm *E* owing to the presence of occasional periods during which the ionization is present continuously for more than 24 hr. If these periods are omitted, the diurnal range becomes comparable to that found for the storm *E*, and most of the disturbances occur within ± 3 hr. of the maximum.

The time of maximum rate of occurrence near the centre of the storm belt varies in a most remarkable manner with longitude. The form of this varia-

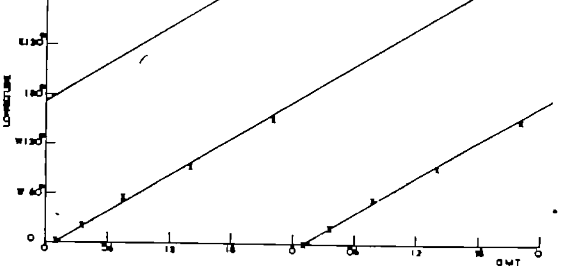

Fig. 2. Positions of storm *D*-zone maximum activity with time

tion may be clarified by plotting the longitudes at which it is found at different universal times (Fig. 2). As may be seen, the observed points, which are based on three years results in most cases, lie on a pair of straight lines separated by 180° (or 24 hr.), each of which repeats every 48 hr. Thus we can demonstrate the existence, at any instant, of two centres of activity on the *D*-region spaced 180° apart which rotate once around the earth every 48 hr. In contrast to the storm *E*, the probability of occurrence of storm *D* near the centre of the storm belt is almost constant throughout the western hemisphere between Sweden and Alaska.

The less intense forms of storm *D* perturbation, which do not completely attenuate all signals, have more complicated variations which combine the characteristics of the storm *E* and storm *D* perturbations discussed above.

An examination of individual disturbances shows that there is a close connexion between the areas affected by active *D* centres, *F*2-region perturbations and abnormally intense local magnetic activity.

The work described above was carried out as part of the programme of the Radio Research Board, and this note is published by permission of the Director of Radio Research of the Department of Scientific and Industrial Research.

## Insulin and the Permeability of Cell Membranes to Glucose

THE effect of insulin in accelerating the peripheral utilization of glucose is generally ascribed to an action on the enzymic carrier system responsible for the intracellular oxidation of glucose, in which the first step is the hexokinase reaction.

More recently, evidence has accumulated suggesting that the locus of action of insulin may be, not on intracellular enzymes, but upon the transport mechanism whereby glucose is transferred across the cell membrane from the extracellular to the intracellular fluids. Such evidence is to be found in the work of Levine and his colleagues[1] on the effect of insulin on the distribution of galactose between the blood and the tissues, and in the effect of insulin in accelerating the rate of transfer of glucose across the blood-aqueous barrier[2].

This concept is further strengthened by studies on the uptake of glucose and other sugars by the isolated rabbit lens. Pairs of lenses immediately on removal from the eyes of anaesthetized rabbits were decapsulated and quickly weighed. They were then placed in tubes containing 3 ml. of Krebs–Henseleit–Ringer phosphate solution, *p*H 7·4, at 37° C. A sample of aqueous humour from one of these eyes had previously been removed by paracentesis and its glucose concentration estimated. Glucose was added to the medium so that its glucose concentration was identical with that of this aqueous humour. One unit of soluble insulin was added to one of the tubes, and both were incubated at 37° C. for 3 hr.; samples were removed from both tubes after 10, 60 and 180 min.

The mean uptake of glucose by the normal lens was 0·202 mgm./gm. lens substance/hr.; in the presence of insulin the uptake was 0·71 mgm./gm./hr. Insulin had thus accelerated the rate of uptake by 350 per cent. When homogenates of lens tissue were used, the rate of uptake of glucose was accelerated by only 33 per cent. When galactose was added to the medium and one hour allowed for equilibration, there was no uptake of galactose by the normal lens; but in the presence of insulin the uptake was 0·11 mgm./gm./hr. When sucrose was similarly employed, there was no uptake either in the presence or absence of insulin.

Insulin greatly accelerates the rate of glucose assimilation by the intact lens, but does so to a much less extent in homogenates in which the cell membranes have been broken down. Although the normal lens did not utilize galactose, nevertheless galactose is transferred into the cell in the presence of insulin; it is of interest to note that such lenses became opaque much more quickly than did lenses in the absence of galactose, suggesting that galactose blocks the glucose utilization mechanism. There is no specialized system for the transport of sucrose across the cell membrane, and hence insulin cannot promote the uptake of sucrose.

This work affords added support for the concept that an important action of insulin is to increase the permeability of cell membranes to biologically important sugars by accelerating an enzymic transport mechanism, and that in its absence such substances must enter the cell by solution in the cell membrane or by passage through 'pores'. The low lipoid solubility and high molecular weight of the sugars mean that their rate of entry by these routes would be slow, so that the organism, in the course of evolution, has developed these specific accelerator mechanisms to facilitate the entry of an adequate amount of glucose into the cell. The hyperglycaemia of diabetes mellitus is the result of the inability of glucose to enter the cells, rather than of a failure of intracellular enzymic oxidations. The intracellular oxidations essential for the life of the cell are maintained in diabetes mellitus largely by the utilization of 2-carbon-atom fragments obtained from the breakdown of fats, which are able to enter the cell because of their high lipoid solubility.

## Histochemical Detection with Ditetrazolium Chloride of some Enzymatic Activities in Isolated Mitochondria

IN an earlier paper[1], I have reported that ditetrazolium chloride, a substance introduced by Seligman and Ruthenburg[2] for the histochemical detection of succinoxidase in tissue sections, can also be used for the detection of the same enzyme in mitochondria isolated from kidney and liver. This has been recently confirmed by Schiebler[3] on the granula isolated from the neurohypophysis by differential sedimentation.

OXIDATION OF SOME SUBSTRATES BY RAT LIVER AND KIDNEY MITOCHONDRIA AS SHOWN BY THE REACTION OF DITETRAZOLIUM CHLORIDE (—, negative reaction; +−, very weak positive reaction; +, weak positive reaction; ++, positive reaction; +++, strong positive reaction; ++++, very strong positive reaction)

| Substrate added | Liver |  |  |  |  |  | Kidney |  |  |  |  |  |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
|  | Reading after |  |  |  |  |  | Reading after |  |  |  |  |  |
|  | 30 min. | 1 hr. | 2 hr. | 6 hr. | 12 hr. | 24 hr. | 30 min. | 1 hr. | 2 hr. | 6 hr. | 12 hr. | 24 hr. |
| Sodium lactate | ++ | +++ | ++++ | ++++ | ++++ | ++++ | ++ | +++ | ++++ | ++++ | ++++ | ++++ |
| Sodium *dl*-malate | +− | + | ++ | ++ | ++ | +++ | +− | ++ | ++ | ++ | ++ | +++ |
| Sodium α-glycerophosphate | +− | + | + | ++ | ++ | +++ | + | ++ | +++ | +++ | +++ | +++ |
| *dl*-Alanine | +− | +− | + | + | + | ++ | + | ++ | ++ | ++ | +++ | +++ |
| *l*(+)-Alanine | − | − | − | − | − | − | − | − | − | − | − | − |
| Sodium glutamate | − | − | − | − | − | − | − | − | − | − | − | − |
| Tyramine | − | +− | +− | + | + | + | − | +− | +− | + | + | + |
| Hypoxanthine | − | − | − | − | − | − | − | − | +− | + | + | ++ |
| Sodium butyrate | − | − | − | − | − | − | − | − | − | − | − | − |
| Ethanol | − | − | − | − | − | +− | − | − | − | − | − | − |
| Glucose | − | − | − | − | − | − | − | − | − | − | − | − |

Since ditetrazolium chloride is an indicator for oxidation-reduction processes, an investigation was begun to determine if this substance could also be used for the histochemical detection of other enzymatic activities in isolated mitochondria.

Mitochondria were isolated from rat liver and kidney by Schneider's method. A small amount of the mitochondrial sediment was stratified on the interior surface of small tubes, and a mixture containing one part of ditetrazolium chloride (1 mgm. per ml. of distilled water), one part of physiological saline, one part of 0·01 *M* phosphate buffer solution (*p*H 7·4) and one part of the substrate solution was added until the final volume of 1 ml. was obtained. Control was made by omitting either the substrate or the colour solution. The tubes were then kept in a thermostat at 38° C. Readings were made after 30 min., 1 hr., 2 hr., 6 hr., 12 hr. and 24 hr.; when a blue colour was given, it indicated a positive reaction.

The following substrates were used, at the concentration indicated: sodium lactate 1 *M*, sodium α-glycerophosphate 0·2 *M*, sodium *dl*-malate 0·2 *M*, *dl*-alanine 0·2 *M*, *l*(+)-alanine 0·2 *M*, *dl*-glutamate 0·2 *M*, tyramine hydrochloride 0·25 *M*, sodium butyrate 0·2 *M*, glucose 0·2 *M*, ethanol 1 mgm., hypoxanthine 1 mgm. The results obtained are shown in the table. It was observed that the ditetrazolium chloride permits the histochemical detection in isolated mitochondria of lactodehydrogenase, of α-glycerophosphate dehydrogenase and of malic oxidase, which gave very strong positive reactions.

The reaction was also positive for *d*-amino-acid oxidase, oxidation of *dl*-alanine being more intense in kidney than in liver mitochondria. Very weak reactions were obtained for tyraminoxidase in both liver and kidney and for xanthinoxidase only in kidney mitochondria. The reaction was negative for alcoholdehydrogenase, glucosedehydrogenase, *l*-amino-acid oxidase and for the oxidases of glutamic and butyric acids.

The results obtained by this histochemical method agree with those previously obtained by manometric techniques on the localization in mitochondria of lactic dehydrogenase[5], α-glycerophosphate dehydrogenase[6], malic dehydrogenase[7] and *d*-amino-acid oxidase[8,9].

The negative reaction given by other enzymes, such as *l*-amino-acid oxidase and alcoholdehydrogenase, which were found to be present in mitochondria by other techniques, can be attributed to the low intensity of these enzymatic activities.

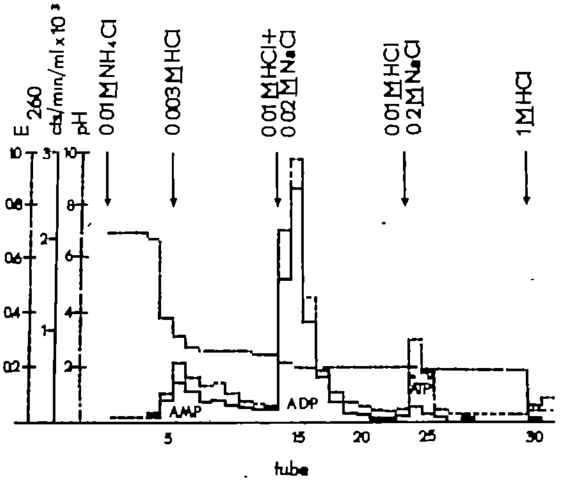
## Formation of Adenine Nucleotides from Adenine by Pigeon Liver Homogenates

ALTHOUGH the mechanism of the formation of inosinic acid from hypoxanthine[1] or glycine and formic acid[2], and the phosphorylation of adenosine to form 5-adenylic acid[3,4], have been studied in cell-free systems, the participation of adenine in nucleotide synthesis has received little attention. During an investigation of the pathway of incorporation of radioactive adenine into ribonucleic acid by *in vitro* systems in this laboratory, it was found that homogenates of pigeon liver were very active in the formation of acid-soluble adenine nucleotides within a short time.

In a typical experiment, 2·5 µ*M* of adenine-8-$^{14}$C hydrochloride[5] (containing 3·4 × $10^5$ counts/min. corresponding to 2·2 µC. carbon-14) were incubated at 37° for 20 min. with 15 ml. of a pigeon liver homogenate containing 2 gm. of tissue in the following medium: 0·13 *M* potassium chloride, 0·015 *M* potassium dihydrogen phosphate, 0·0046 *M* sodium bicarbonate, 0·0001 *M* sodium fluoride, 0·002 *M* magnesium sulphate brought to *p*H 7·1 with ammonia. The barium salts of the nucleotides were precipitated from the acid-soluble fraction at *p*H 8·2 in 80 per cent alcohol by the method of LePage[6]. A diluted solution of the regenerated barium-free nucleotides was brought to *p*H 5·6 and passed through a 'Dowex-1-chloride' column (3·5 cm. × 0·8 cm.$^2$). The effluent contained an, as yet, unidentified substance which seems not to be identical with adenine, adenosine, 5-adenylic acid, adenosine di- or tri-phosphate. Further work is



Ion-exchange separation of adenine nucleotides from acid-soluble fraction after 20 min. incubation of pigeon liver homogenate with adenine-8-$^{14}C$

being done to determine the composition of this material, since in some experiments it contains a fairly large proportion of the original radiocarbon.

The column was then eluted according to the method of Cohn[7], as shown in the accompanying diagram, and 10-ml. fractions were collected. The pH extinctions at 260 mμ and carbon-14 were determined for each fraction and the results are summarized in the diagram.

It can be seen that the relatively small amount of adenine incubated with the tissue was mainly converted to the adenosine-5′-phosphoric acids. The identity of the adenosine monophosphate was confirmed by the differential enzymatic spectrophotometric method of Kalckar[8] with 5-adenylic acid deaminase prepared from rabbit muscle. All the absorption at 260 mμ was due to material which could be deaminated by the enzyme. The fractions marked ADP and ATP (adenosine di- and tri-phosphate) were similarly analysed by using a preparation of potato apyrase along with the 5-adenylic acid deaminase. While the adenosine diphosphate fraction reacted quantitatively with the enzymes, the content of adenosine triphosphate determined enzymatically was about one-half that indicated by the 260-mμ absorption. This may account for the lower relative count observed. It can be calculated that the activities of the adenosine mono- and di-phosphate correspond to a fourfold dilution of the original adenine.

The proportions and activities of adenosine mono-, di- and tri-phosphate vary considerably from one experiment to another, but the total counts found in the three nucleotides were usually 40–70 per cent of the initial carbon-14 added.

In another experiment the material which was not precipitable by barium and alcohol was analysed by paper chromatography; it was found to consist solely of labelled hypoxanthine with a specific activity corresponding to a sixfold dilution of the original adenine. A study of the formation of hypoxanthine as a function of time indicated that it is probably not derived directly from adenine, as has been suggested[9] for rabbit marrow slices.

The possibility that adenosine is the intermediate between adenine and adenosine monophosphate is now being investigated, as is the isolation of the enzymes responsible for the formation of 5-adenylic acid.

I wish to thank Dr. H. M. Kalckar for supplying me with the labelled adenine, and to acknowledge his stimulating criticisms and guidance. This work was performed under a fellowship of the American Cancer Society, Inc., recommended by the Committee on Growth, U.S. National Research Council.

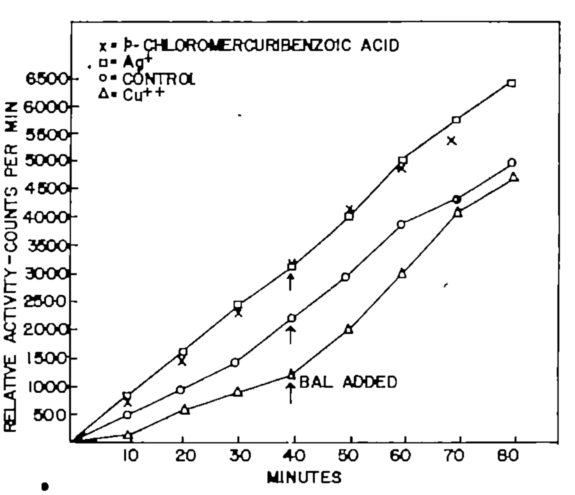
## Effect of Sulphydryl Reactants on Liver Ribonuclease

WHILE investigating the characteristics of rat liver ribonuclease it was noted that several reagents which react with sulphydryl groups increased the activity of this enzyme in homogenates. $4 \times 10^{-4}$ *M* silver or lead ions increased the activity approximately 25 per cent, while saturation of the test system with *p*-chloromercuribenzoic acid or phenyl mercuric chloride caused a similar increase. Cupric ion of $4 \times 10^{-4}$ *M* concentration was, however, inhibitory to the extent of 50 per cent. The inhibitory action of cupric ions could be reversed by the addition of 2,3-dimercaptopropanol (BAL); but this compound had no effect on systems containing the other sulphydryl reacting agents, or on the enzyme alone. The accompanying graph shows the results of a typical experiment.

The method of Roth and Milstein[1] was employed for the assay, and the control contained 10·0 ml. of veronal-acetate buffer of *p*H 7·75 and 0·17 *M* with respect to sodium ion; 2·0 ml. of 1 : 50 rat liver



Effect of sulphydryl-reacting agents on the activity of rat liver ribonuclease homogenate and 3·0 ml. of distilled water. 1·0 ml. of 0·01 *M* lead chloride, silver nitrate or cupric chloride was substituted for 1·0 ml. of distilled water in separate flasks, while 10·0 mgm. of *p*-chloromercuribenzoic acid or phenyl mercuric chloride was added to other flasks containing the same components as the control. At zero time, 10·0 ml. of 1 per cent labelled yeast ribonucleic acid was added to each of the flasks, and after 40 min. 50 mgm. of 2,3-dimercaptopropanol was added to each. At 10-min. intervals, 3·0-ml. samples were withdrawn from the mixtures and to them was added 3·0 ml. of 1·0 *M* hydrochloric acid in 76 per cent ethanol. Blanks in which 2·0 ml. of water were substituted for the liver homogenate were run for each of the test systems. After addition of the acid-alcohol, the solutions were filtered and the radioactivity determined on an aliquot of the clear filtrate. The radioactivity of the blank filtrates was subtracted from the respective experimental filtrates to give the values shown in the graph. In general, the sulphydryl reactants had negligible effect on the substrate, although methyl glyoxal caused an increase in the acid solubility of the ribonucleic acid. This increase in acid solubility did not occur below *p*H 6, however.

Although other explanations are possible from the results obtained, it appeared likely that a sulphydryl-containing substance in liver homogenates was acting as a ribonuclease inhibitor, and that sulphydryl reactants could counteract this inhibition, at least in part. The anomalous action of cupric ions may be due to direct combination of this ion with the enzyme or substrate in preference to the inhibitor. As further evidence for the presence of a ribonuclease inhibitor in liver homogenates, it has been found that the sum of the activities of separate liver and kidney homogenates is greater than the activity of the same homogenates when mixed. Recently, Pirotte and Desreux have described an inhibitor for ribonuclease in guinea pig liver[4].

The presence of an inhibitor in liver which is absent from kidney might explain the considerably smaller ribonuclease activity of liver. The liver inhibitor may be heparin or a heparin–lipoprotein complex[5] which has been shown to contain cysteine, and it has been demonstrated that heparin is a potent inhibitor of ribonucleases[6]. Further work is in progress to determine the nature of these phenomena and their relation to cell division and growth.

## Sudden-Death Disease of the Clove Tree, *Eugenia aromatica*

THE clove crop of the Zanzibar Protectorate, on which the economy of the islands is largely based, and which provides nine-tenths of the world's supplies, is seriously threatened by the sudden-death disease. In 1950, it was estimated that at least half of the clove trees in Zanzibar Island had already been killed by this disease, and that in the island of Pemba there were more than two thousand separate outbreaks[1]. The disease has made rapid progress since that date.

An organization for research into clove diseases was set up by the Colonial Office in 1947. Preliminary field studies showed that sudden-death was almost certainly caused by a pathogen, and a virus was considered the most probable[2]. For three years, however, every known technique for revealing the presence of a virus was used with consistently negative results.

This led us, late in 1950, seriously to re-examine the possibility of a fungal cause, a hypothesis which had been considered unlikely, as it was generally believed that this had been disproved by previous workers. We then found that sudden-death is invariably associated with a hitherto undescribed species of *Valsa*. The absorbing roots die at a comparatively early stage of the disease, and the fungus can then be isolated from the distal parts of the root system. It can be found at the collar a week or more after death and afterwards spreads rapidly throughout the tree, producing an intense yellow colour in the invaded tissues. Extensive surveys have shown no instance of sudden-death where this *Valsa* was absent, and we have never found it in trees which have been killed by other agencies, such as fire, drought or severe dieback. Furthermore, we have failed to find any other fungus consistently associated with the disease.

Experiments have shown that *Valsa* can readily invade the tissues of mature clove trees, that young trees are comparatively resistant, and that seedlings are immune. Field experiments in which massive spore suspensions have been applied over a period of some months to uninjured roots of mature trees have demonstrated that the absorbing roots are attacked by the fungus, which later invades the fibrous root system, advancing in the cambial region, whence it spreads to other tissues.

Young clove saplings, between the ages of about eight and eighteen years, frequently suffer from a progressive decline over some years, accompanied by a root rot; this occurs in plantings in areas previously devastated by sudden-death and in which the old stumps are almost invariably left standing. We have found *Valsa* associated with this root rot, and consider the disease to be the symptom-expression of attack on young trees which are not yet fully susceptible to this fungus, and thus to be a form of the sudden-death disease.

It is not known how new outbreaks of sudden-death arise in previously disease-free areas, of which only a few still remain. We think it significant that in trees in these areas, as in the infected parts of the islands, *Valsa* can often be found acting as a wound parasite and causing a branch dieback.

Details of this work will be reported elsewhere.

## A Freshwater Eel on Zanzibar Island

Playfair and Gunther's "Fishes of Zanzibar", 1866, bears a somewhat misleading title, for some of the species included come from places other than Zanzibar, some quite distant.

"Zanzibar" to-day means Zanzibar Island itself, whereas in earlier times the dominion and name extended over a wide area, including the coastal regions of East Africa. In consequence, creatures unknown from the Island itself have been recorded as occurring in "Zanzibar". One such is the freshwater eel, *Muræna mossambica* Peters, 1844.

Owing partly to the porous nature of the Island, there are few and restricted bodies of fresh water on Zanzibar, and there is only one run of water which merits naming as a river, and that disappears before it reaches the sea. The wide fluctuations in ocean-level during the Pleistocene would, in periods, have reduced the present Zanzibar Island to at most a group of islets, with almost certain extinction of most of the purely freshwater fauna of the more extensive lower drowned levels. During the recessions of the glacial periods some of this may have been restored; but there is no evidence that the larger rivers of the adjacent mainland flowed near Zanzibar. It is therefore not surprising that there is only a severely restricted freshwater ichthyfauna on the Island, only three or four species having been found there. In passing, it may be indicated that some of the recent wide fluctuations in ocean-level may well provide a clue to the explanation of at least some of the puzzling features in the land fauna of Mafia, Zanzibar and Pemba.

In current ichthyological literature, the freshwater eel is listed as occurring in Zanzibar. No less than three species, namely, *mossambica* Peters, 1844, *bengalensis* Gray, 1830, and *australis* Richards, 1841, are stated to be present in Zanzibar by Boulenger ("Freshwater Fishes of Africa", 3; 1915). These are apparently based on specimens recorded in Playfair and Gunther's "Fishes of Zanzibar" of 1866. A record of *mauritiana* Bennett, 1831, from Zanzibar by Weber and de Beaufort ("Fishes of the Indo-Australian Archipelago", 3, 247; 1916) is presumably based on the record of *A. johannæ* in Playfair and Gunther's "Fishes of Zanzibar".

Investigation reveals that none of the records is from Zanzibar Island itself, and so far as may be ascertained there is no authentic record of any species of freshwater eel having been found there. If the marine origin of the eels of this region be accepted, as they are found in the Ruvu and Pangani Rivers of the adjacent mainland, but for the accident that only comparative trickles of fresh water reach the sea from Zanzibar Island, it is surprising that no eels have ever been found there.

During a recent visit to investigate the fish life of the Zanzibar area, I inquired into the matter of the freshwater fishes, which have been investigated by several people during the past hundred years; but no further discoveries have been made in that period. Towards the close of my stay I learned that a large 'water snake' had been seen in a disused reservoir in which the lower "Chem-Chem" spring is completely enclosed; this structure is an unfortunate experiment by an engineer of earlier times, it is said, for he had failed to determine in advance the hydrostatic level of the source of the water. At my request the authorities kindly agreed to assist, and by means of a portable pump the water in this enclosed and roofed structure was reduced to a level where it kept pace with the restored flow through the porous coral rock. No life was visible in the considerable body of water remaining; but by means of an irritant chemical and nets, we soon captured the 'water snake', which proved to be a 30-in. well-nourished specimen of *Muræna mossambica* Peters, 1844, apparently the first to be known from Zanzibar Island.

This spring lies less than half a mile from the sea; but how the fish got into it is a mystery, as no water has ever flowed out of it, and the manholes in the roof of the enclosing structure have iron covers, supposed to have been kept closed for many years. It is just possible that a minute elver might have come through the eye of the spring, but not very likely in view of the absence of flow. The aliments in this specimen have not yet been examined, but its food can have consisted of little else than insects, and most likely of the smallest only.

## Encapsulation in Rumen Bacterial Fractions

METHODS of fractionating the rumen contents of sheep previously described in the literature (see, for example, footnote 1) involve centrifugation of uncooled, strained, rumen liquids at varying speeds on centrifuges running at room temperature. These procedures were found by us to be unsatisfactory for two reasons. First, during the time between collection and centrifugation of the liquids, the composition of the sample might alter as a result of bacterial fermentation and autolysis; and secondly, during the centrifugation, especially at high speeds, the liquids warm up to as much as 40° C., thus setting up convection currents in the centrifugate and causing fermentation with the liberation of gases which break up the sediments. We have found that these difficulties are overcome by the following procedure, which allows of fractionation on a small scale.

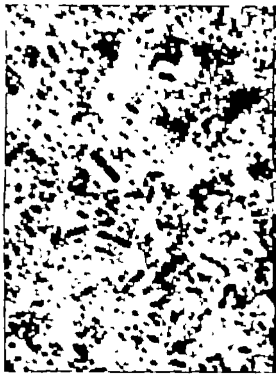
Rumen contents were collected through a permanent rumen fistula[2] by means of a wide-bore glass tube fitted with a rubber suction bulb, and immediately pipetted into a conical flask cooled in a freezing mixture of ice and salt, which reduced the temperature of the rumen contents to *c.* + 1° C. in 10–15 min. Further operations were then carried out in a cold room at + 1° C. The rumen contents were strained through a 60-gauge copper gauze to remove plant particles. (It is well to note that, if the fractions are required for cultural studies, the copper gauze should be replaced by bolting silk, as small traces of copper have a bactericidal effect.) The resulting liquid was centrifuged for 20 min. at 22,500 *g* in a 'Superspeed' head on a refrigerated centrifuge (M. S. E., London), conditions being adjusted so that the rumen liquid remained at + 1° to + 3° during centrifugation. If the temperature was further lowered, ice began to separate from the liquid.

Two sheep were used in the experiments. One was fed mixed concentrates (250 gm.) and potato starch (100 gm.), twice daily, with one feed of hay (250 gm.) in between, and the other was fed on hay (*ad lib.*). The rumen contents were sampled three hours after the morning feed. The samples from the starch-fed sheep were thick and formed four distinct

| Fraction No. | Appearance | Constituents |
|---|---|---|
| 1 | Brown opalescent liquid | Almost bacteria-free; few Gram-positive cocci and Gram-negative bacilli |
| 2 | White semi-solid layer | Almost entirely Gram-negative bacilli, cocci and vibrios; few Gram-positive cocci and bacilli |
| 3 | Fine green compact sediment | Protozoa, selenomonas and bacteria, as in fraction 2, plant particles and starch granules |
| 4 | Coarse material | Mostly plant particles, with some bacteria and protozoa |

fractions on centrifuging. These are described in the accompanying table.

Fractions 1 and 2 from the rumen liquids of the hay-fed sheep were similar to those from the starch-fed animal, but fractions 3 and 4 formed a single layer. The sediments were easily separated by repeated washing with a small volume of phosphate buffer (0·1 *M*; *p*H 7·0). A photomicrograph of a typical bacterial fraction (2) from the rumen liquids of a starch-fed sheep is shown in Fig. 1.



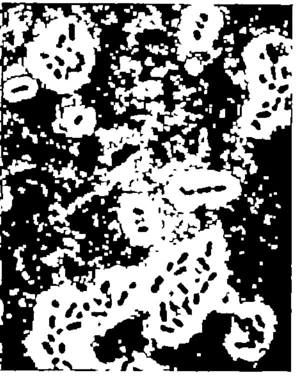


Fig. 1. Bacterial fraction 2 from a sheep on a starch-containing diet. Stained by Gram's method. × 1,500

Fig. 2. Bacterial fraction 2 from a sheep on a starch-containing diet. Wet indian ink preparation, more dilute than Fig. 1, showing extensive encapsulation. Phase contrast. × 1,650

Examination of fraction 2 by Duguid's indian ink technique[3] showed that large numbers of the bacteria were heavily encapsulated, a fact which has not been noted in fractions prepared by the usual methods. The largest capsules, up to 9 µ in transverse diameter, were found on the bacteria from the hay-fed sheep. In the fraction from the starch-fed sheep large clumps of agglutinated bacteria surrounded by capsular material were seen. Moir and Masson[4] have recently described a survey of whole rumen contents, either fresh or incubated *in vitro* for one hour with glucose, in which they noted some encapsulated organisms. The present work suggests that encapsulated organisms constitute a large part of the bacterial fractions. This capsular material appears, from preliminary experiments on a strain of rumen streptococcus isolated in pure culture[5], to contain polysaccharide which, like the majority of the bacterial capsular materials so far investigated, does not stain with iodine. However, whether this capsular material can be utilized by the host animal at a later stage in the digestion cycle, as can starch-type intracellular polysaccharides[6], or can be converted by other bacteria into products of value to the host cannot yet be stated.

We wish to thank Dr. A. E. Oxford for interest shown in this work and for placing the hay-fed sheep at our disposal.

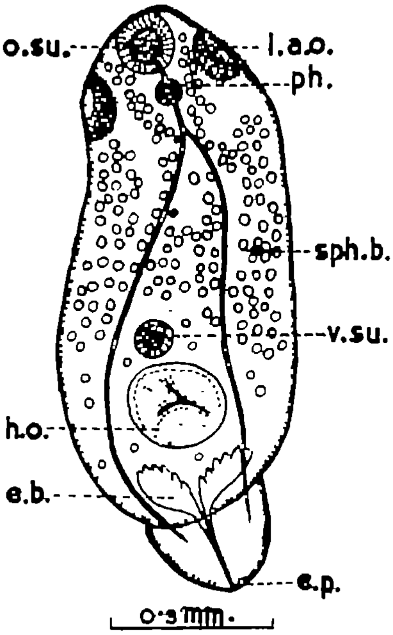
## A New Trematode Metacercaria from the Eyes of Trout

Several workers[1-4] have reported the occurrence of eye metacercariæ from various British freshwater fishes, and all have regarded their specimens as *Diplostomum volvens*. This, as described originally by Nordmann (1832) and reported later by various workers, has an oral sucker much smaller than the ventral, and its lateral adhesive organs are never in the form of cup-shaped structures. Moreover, its ventral sucker is also shown to be pre-equatorial in position. During an investigation on the trematodes of the brown trout, *Salmo trutta* L., at Edinburgh, I obtained, mostly from the vitreous humour of the eye, a metacercaria in which the oral sucker was much larger than the ventral, the lateral adhesive organs formed cup-shaped sucker-like structures and the ventral sucker was post-equatorial in position. It is, therefore, distinct from *Diplostomum volvens*. Furthermore, the present metacercaria on comparison comes nearer to some of the American and Australian species of *Diplostomulum* but differs from all these in several important features. It is, therefore, regarded as a new species and designated *Diplostomulum truttæ* n.sp. (*Diplostomulum* being the name given to eye metacercaria of which the adult has not yet been identified).

Its abbreviated specific description is as follows. The fore-body is large and the hind-body very small; at the lateral sides of the anterior end are deep cup-shaped sucker-like structures which can be protruded as ear-like lateral adhesive organs (*l.a.o.*). In a specimen of about 1·1 mm. length, the oral sucker (*o.su.*) measures 0·11 mm. in diameter and the ventral sucker (*v.su.*), which is post-equatorial and much smaller than the oral, measures 0·075 mm. in diameter. A short prepharynx leads into a globular pharynx (*ph.*), followed by a short œsophagus and two intestinal cæca extending into the hindbody. A well-developed holdfast organ (*h.o.*) lies posterior to the ventral sucker. Minute papillæ cover the body cuticle and a large number of spheroidal bodies (*sph.b.*) occur internally, especially concentrated in the middle third of the forebody. A well-developed bilobed excretory bladder (*e.b.*) opens postero-dorsally at the excretory pore (*e.p.*). In some living examples a number of longitudinal and transverse excretory vessels with about twenty-four flame cells could be made out.



*Diplostomulum truttae* n.sp., showing body structures

This metacercaria is widely distributed in Scotland. It is with great pleasure that I thank Prof. James Ritchie for providing me with facilities to carry out this investigation in the University of Edinburgh.

## Growth and Axon Formation in the Midbrain of the Chicken Embryo

IN the development of anterior horn cells, Hydén[1] recognizes three successive phases. The first is one of intensive growth without axon formation. In the second, growth is diminished, but axon formation occurs. In the third phase, growth is again intensive and associated with continued axon formation. The resulting peripheral axon can, in the adult, be regenerated by a 'revival' of this stage.

It is thus of interest to inquire whether equivalent phases occur in the development of nerve cells the axons of which remain within the central nervous system and which cannot regenerate. In the chicken embryo, such cells are found in the dorsal region of the midbrain vesicle which contributes to the corpora bigemina, and observations have been made on this region.

As in other parts of the central nervous system, axon formation cannot be demonstrated in the cells of the ependymal layer; but, in the earlier stages of development, these cells grow and divide rapidly and correspond to the first phase. However, when cells pass from the ependymal to the mantle layer, axon formation occurs. The developing axons accumulate in the more peripheral marginal layer, the width of which is, for a time, an indication of the amount of axon material formed by the mantle cells immediately underlying any particular region. Although this relationship becomes modified by the ingrowth and outgrowth of axons, the modification is not important before the eighth day of incubation. Hoadley[2] transplanted the three-day midbrain on to the chorio-allantoic membrane and, five days later, found that, although smaller than the controls, the transplanted midbrains had a normal architecture, achieved in the absence of ingrowing or outgrowing axons.

Since cell division does not occur in mantle cells, these would conform to the second phase if, while a significant amount of axon formation took place, there was little or no increase in cell size. The average volume of the cells was determined by counting the nuclei in measured areas of histological sections of known thickness. It was found that the volume of the mantle cells did not vary by more than ± 10 per cent in the period 3–8 days of incubation, although measurements of the diameters of the midbrain indicated an increase in its volume of more than a hundred times. In the same period the non-nucleated axon-containing layers increased from 2 to 40 per cent of the total width of the midbrain wall. Hence, in the period 3–8 days of incubation, mantle cells form axon material equivalent to about 40 per cent of their bulk without increasing in size, and thus conform to the second phase described in the development of anterior horn cells.

During the 3–8 day period, growth of the midbrain as a whole must be due to growth and division of cells in the ependymal layer. However, dividing cells disappear from this layer after the eighth day of incubation, so that subsequent growth of the midbrain can be assumed to require increase in size of individual cells. Further, these cells must continue to form axon material in order to make and maintain connexions with other parts of the central nervous system—a combination of growth and axon formation similar to that described above in the third developmental phase. Thus, the three phases occurring in the development of the anterior horn cells have their equivalent in the development of the cells of the midbrain, which, in contrast to the anterior horn cells, produce axons that do not leave the central nervous system and which are incapable of regeneration.

## Neurosecretory Pathways in the Prawn, *Leander serratus*

LAST year, I reported the presence of neurosecretory cells within the tritocerebral commissure of *Penaeus brasiliensis*, and the distribution of fuchsinophil droplets along the course of two post-commissure nerves[1]. Two flat extensions of these nerves, adjoining blood sinuses and therefore described as sinus-plates, were full of these droplets. Injection experiments showed that those regions with the most droplets yielded the most potent extracts when these were tested by their effects on the white chromatophores. The sinus-plates resemble the sinus-glands of the Mysidacea[2], and this parallel has been made

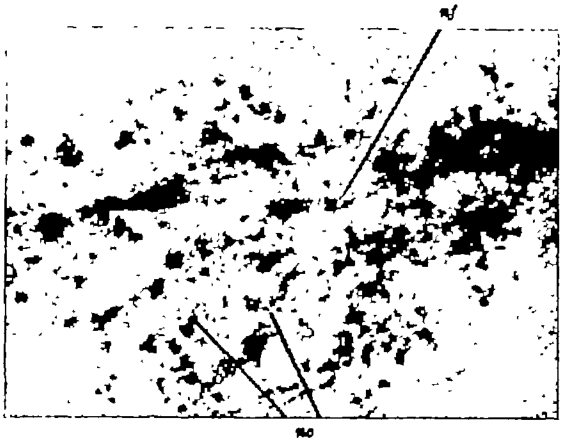

Fig. 1. The wide proximal portion of a post-commissure nerve

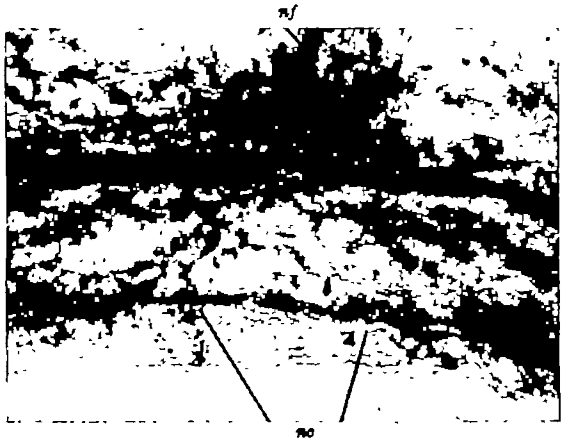

Fig. 2. The commissure at the base of a post-commissure nerve. *nf*, Position of nerve fibres in centre of post-commissure nerve; *nc*, lines of droplets marking the position of possible neurosecretory channels

more striking by the recent evidence of Enami[3], Passano[4] and others that the sinus-glands of some decapods are supplied by neurosecretory cells in the medulla terminalis; the secretory products pass along nerves and are released via secretory canals in the sinus-glands[2]. In the present experiments a search was made for secretory canals in the tritocerebral commissure and the post-commissure nerves of the prawn, *Leander serratus*. The nervous system was stained by a modification of the methylene blue method used by Alexandrowicz[5]; specimens were immersed in a solution of methylene blue for nine hours in a refrigerator.

Each post-commissure nerve of *Leander serratus* is broad and flat for the first half of its length. Nerve fibres lie along its centre and the remainder is filled by droplets which stain with methylene blue. These droplets are not dispersed at random but lie in lines, apparently along branched channels which radiate from the central fibres (Fig. 1). There is insufficient evidence at present to show whether these 'channels' are, in fact, axon fibres, though they seem to lie more superficially than the fibres, apparently within the tissue of the epineurium. Similar channels, marked by the position of droplets, radiate from the bases of the post-commissure nerves for some distance over the upper and the lower surfaces of the commissure (Fig. 2). Two slightly deeper channels extend from the bases of the post-commissure nerves to two large cells which lie in a median position within the hinder margin of the commissure.

One cannot ignore the possibility that the droplets which stain so readily with methylene blue are, in fact, artefacts, but I am inclined to consider them as secretory droplets for the following reasons: (1) they correspond in position to fuchsinophil droplets observed in serial sections of the commissure region of *Leander affinis*; (2) they are very numerous in the post-commissure nerves and in the commissure near by, but are sparse or absent in the rest of the commissure and in the connectives, and there is some degree of correlation between the concentration of droplets and the potency of extracts obtained from the different areas. The injection of extracts of the post-commissure nerves and of the adjacent region of the commissure was followed by a prolonged concentration of the white chromatophores and a brief concentration of the red chromatophores in normal and eyeless animals. Extracts of the nearby connectives, on the other hand, promoted only a slight and a brief concentration of the red and the white chromatophores.

Serial sections of the commissure have revealed evidence of secretory activity in the two large cells within the hinder margin of the commissure. It seems probable that a chromatophorotropin is produced by these cells, conveyed to the bases of the post-commissure nerves, and thence distributed, stored, possibly elaborated and released along channels in the epineurium of the commissure and that of the post-commissure nerves, the latter being especially important. This interpretation of the post-commissure nerves as reservoirs and distributors of material produced by secretory cells within the nervous system agrees with current concepts of the X-organ–sinus-gland relationship in crustaceans[1], the pars intercerebralis–corpora cardiaca system in insects[6], and the hypothalamo–hypophyseal system in vertebrates[7].

The work was done at the Stazione Zoologica, Naples, Italy.

## A Growth-Inhibitor for Streptomycin-resistant Mutants in Dense Suspensions of *Brucella abortus* (Strain 19)

It was observed that when bacterial suspensions in broth were exposed to streptomycin in a concentration of 100 μgm. per ml. the survivors multiplied slowly after a prolonged lag phase[1]. It was also observed that, when bacterial suspensions containing 320–1,600 millions of *Brucellae* per 10 ml. were exposed to streptomycin, then the resistant mutants appeared in them more frequently than in those containing 1,600–8,000 millions of *Brucellae* in the same volume[1].

In order to determine whether the lower rate of appearance of resistant mutants in bacterial suspensions of high density exposed to streptomycin was due to an inhibiting action of the dead bacteria on the survivors, the following experiment was carried out.

2-ml. portions of suspension of *B. abortus* (Strain 19) containing 6 × $10^9$ micro-organisms and streptomycin were distributed into seven series of test-tubes and Erlenmeyer flasks containing varying quantities of trypticase-soy-broth with streptomycin (100 μgm. per ml.). The varying quantities of broth were 0, 2, 4, 6, 10, 18 and 38 ml.; the densities of the bacterial suspension varied, therefore, and were 3 × $10^9$, 1·5 × $10^9$, 1 × $10^9$, 7·5 × $10^8$, 5 × $10^8$, 3 × $10^8$ and 1·5 × $10^8$, while the bacterial population was the same in each sample (6 × $10^9$). Ten replicas were prepared from every sample of bacterial density. By plating and incubating the bacterial suspension with streptomycin-agar, it was determined that seven resistant mutants were present in 2 ml. among 6 × $10^9$ micro-organisms, or one resistant mutant in a bacterial population of 8·6 × $10^8$. After 11, 14, 20 and 27 days, 0·05-ml. samples were removed from each test-tube and inoculated on to agar plates in order to determine whether resistant mutants had survived and multiplied. The frequency of their appearance from samples of different bacterial density is given in Table 1.

Table 1

| Bacterial density per ml. | Appearance of resistant mutants after an incubation of: 11 days | 14 days. | 20 days | 27 days |
|---|---|---|---|---|
| 3·0 × $10^9$ | 0/10 | 2/10 | 2/10 | 8/10 |
| 1·5 × $10^9$ | 4/10 | 4/10 | 4/10 | 8/10 |
| 1·0 × $10^9$ | 8/10 | 8/10 | 10/10 | 10/10 |
| 7·5 × $10^8$ | 10/10 | 10/10 | 10/10 | 10/10 |
| 5·0 × $10^8$ | 10/10 | 10/10 | 10/10 | 10/10 |
| 3·0 × $10^8$ | 10/10 | 10/10 | 10/10 | 10/10 |
| 1·5 × $10^8$ | 10/10 | 10/10 | 10/10 | 10/10 |

Filtrates of recently prepared bacterial suspensions in streptomycin broth containing 3 × $10^9$ *Brucellae* per ml. did not delay the appearance of resistant mutants. But when these suspensions were kept four months at room temperature, filtered through Seitz filters, diluted and inoculated with 1·5 × $10^9$ *Brucellae* per ml., the delay observed in the appearance of resistant mutants in replicas of five culture-tubes is shown in Table 2.

Table 2

| Concentration of the filtrate | | Appearance of resistant mutants after an incubation of: 6 days | 10 days | 15 days |
|---|---|---|---|---|
| Undiluted | | 0/5 | 2/5 | 2/5 |
| Diluted | 1 . 2 | 1/5 | 1/5 | 1/5 |
| | 1 : 5 | 2/5 | 3/5 | 3/5 |
| | 1 . 10 | 2/5 | 2/5 | 2/5 |
| | 1 : 20 | 3/5 | 4/5 | 4/5 |
| | 1 . 50 | 3/5 | 4/5 | 4/5 |
| | 1 : 100 | 3/5 | 4/5 | 5/5 |
| Control | | 4/5 | 5/5 | 5/5 |

This experiment shows that the inhibiting factor was liberated by autolysis from the bacteria which were killed by the action of streptomycin.

## Additional Photoperiodic Response in Sheep

HITHERTO most work on the photoperiodic behaviour of mammals has been related to their reproductive cycles[1,2]. Hammond, jun.[3], working with mink, was able to demonstrate an effect on the onset of moulting (correlated with new and more rapid growth of hair), when the animals were responding to photoperiodic stimulation by coming into œstrus.

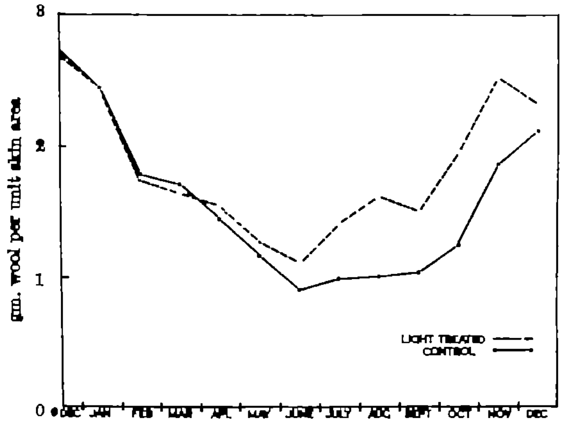
The general opinion among workers that the initial stimulus is received in the eye region and thence proceeds to activate the pituitary body in a gonadotrophic manner remains unaltered, although the exact sequence of events is not yet defined. In an attempt to elucidate further this exteroceptive stimulation of the pituitary body by light–dark sequence, experiments designed to test the nature of the response in sheep were commenced in January 1951. One important aspect of the question is, whether the stimulation is specifically a gonadotrophic one, or whether other hormones known to be elaborated by the pituitary are also involved.

Fourteen mature Corriedale ewes were randomized into two groups, and housed in individual pens in two adjacent rooms. The control group received solar light-rhythm by means of glass skylights in the roof and walls. The experimental group was housed in a blacked-out room and subjected to an artificial light-rhythm consisting of 8 hr. light–16 hr. darkness.

Exactly the same daily ration of concentrates and chaffed lucerne hay was allowed both groups during the experiment. Mean temperatures in the two rooms were approximately the same. All the ewes were mated, and at lambing in September were made to suckle twins if this did not occur naturally.

Monthly clippings from similar tattooed areas of skin were taken from both groups throughout the period. The accompanying graph shows the mean weight of clean scoured wool produced per month from these areas in the two groups.

In addition to wool growth, a study is being made of the photoperiodic effect on (*a*) the lactation curve of the ewes, (*b*) the composition of the milk, and (*c*) the growth-rate of the lambs. It is not possible at this stage to deal with all these aspects of the investigation, which is still in progress, but there is obviously a significant increase in wool-growth amounting to more than 15 per cent throughout the twelve months.



Mean weight of scoured wool

It is suggested that this may be due to the increased activity of the pituitary bodies of the light-treated animals, resulting in an increased output of either growth hormone or thyrotrophic hormone.

## Transfer of Labelled Nitrogen from Glutamic Acid to Pine Seedlings through the Mycelium of *Boletus variegatus* (Sw.) Fr.

IN a previous paper from this Institute[1] it was shown, by using the isotope technique, that hyphæ of *Boletus variegatus* (Sw.) Fr. in mycorrhizal connexion with pine seedlings transfer nitrogen from a solution of an ammonium salt to the roots. The labelled nitrogen was added as ammonium nitrate containing the stable isotope nitrogen-15 in the ammonium group. By a special arrangement, only the mycelium was exposed to the isotope, and then the amounts of nitrogen-15 were measured in different parts of the seedlings.

We have now studied in the same way the transfer of labelled nitrogen from an organic source to pine seedlings by means of mycorrhizal mycelium.

The nitrogen source chosen was glutamic acid. It has been recently demonstrated in this Institute[2] that the growth-rate of many mycorrhizal fungi is increased by certain amino-acids in a nutrient solution containing also ammonium-nitrogen. The growth-rate of *Boletus variegatus* is much increased, particularly by glutamic acid, under these experimental conditions. As a sole source of nitrogen, however, glutamic acid—in contrast to aspartic acid—yielded only a very poor mycelial growth. This seems to indicate that glutamic acid was not deaminated in any high degree by the fungus mycelium. Therefore, labelled glutamic acid seemed suitable for use as a tracer compound.

The experimental method used was as previously described[3]. In wide-necked 500-ml. Erlenmeyer flasks were placed cups near the wall. Both vessels were supplied with purified sand to which was added a nutrient solution containing ammonium phosphate as source of nitrogen. Into each of the Erlenmeyer flasks one aseptic seedling of *Pinus sylvestris* was introduced, and after some time mycelium of *Boletus variegatus* was inoculated in the cups. The cultures were grown during the spring and summer of 1951.

Glutamic acid labelled with nitrogen-15 was kindly synthesized by Dr. S. Wideqvist, Chemical Institute, University of Uppsala. It contained 6·3 atomic per cent of nitrogen-15.

When mycorrhizæ had become well developed, the labelled amino-acid was added to the glass cups in amounts of 50 mgm., that is, about 4·5 mgm. nitrogen. To the sand outside the cups were supplied corresponding quantities of unlabelled acid, to prevent, if possible, diffusion from the hyphæ. Half the cultures were harvested after one and a half days, the others after three days, of exposure.

The seedlings were divided into two sections, namely, (1) stem and needles, (2) the roots. The sections were then treated as previously described[4].

The measurements of nitrogen-15 were made by Dr. G. Ryhage, at the Institute of Chemistry, Stockholm. The mass spectrometer used was of the Nier type and gave a maximal error of 0·002 atomic per cent nitrogen-15 excess when the quantity of total nitrogen was 10 μgm.

In the accompanying table are given the values of the dry weights of the different sections, their total nitrogen content and the atomic per cent nitrogen-15 excess. It is clearly shown that nitrogen has been transported through the *Boletus* mycelium to the pine roots. From the mycorrhizal roots the isotope has further been translocated to the different parts of the seedlings. It may be difficult to prove that the nitrogen really has been delivered to the host tissues as glutamic acid. It may have been transaminated, at least in part, to other amino-acids already in the hyphal cells, and also have entered directly into the metabolic pathways leading to the synthesis of protein.

ATOMIC PER CENT NITROGEN-15 EXCESS IN PINE SEEDLINGS GROWN IN MYCORRHIZAL CONNEXION WITH *Boletus variegatus* EXPOSED TO LABELLED GLUTAMIC ACID

| Plant No. | Portion of seedling | Dry weight (mgm.) | Total nitrogen (mgm.) | Atomic per cent nitrogen-15 excess |
|---|---|---|---|---|
| | | 1½ days of exposure with the isotope | | |
| I | Stem | 97 | 2·98 | 0·010 |
| | Root | 39 | 1·16 | 0·034 |
| II | Stem | 103 | 3·11 | 0·010 |
| | Root | 49 | 1·43 | 0·036 |
| | | 3 days of exposure with the isotope | | |
| III | Stem | 109 | 3·30 | 0·013 |
| | Root | 52 | 1·62 | 0·069 |
| IV | Stem | 99 | 3·02 | 0·012 |
| | Root | 44 | 1·31 | 0·052 |

The experimental evidence leads to the assumption that nitrogen may be transferred to the root tissues through the *Boletus* mycelium from other amino-acids as well as glutamic acid. It may also be assumed that other mycorrhizal fungi of trees have the same ability as the fungus used in this experiment.

This investigation has been supported by a grant from Fonden for Skoglig Forskning, Stockholm.

## Effect of Boron and Molybdenum Fertilizers on Berseem (*Trifolium alexandrinum*)

THE cultivation of berseem, a leguminous forage crop, is gaining in importance in India on account of its high yields of succulent fodder of excellent nutritive value. Phosphatic fertilization of this legume has been found to be very beneficial[1].

Brenchley and Thornton[2], Midgley[3], Naftel[4] and others have shown that boron is essential for proper

growth and development of legumes. It is known that, in symbiotic nitrogen fixation, molybdenum plays an important part[5–7]. In proper doses boron and molybdenum have been reported also to have increased the yield of red clover and lucerne[8,9].

The results of a field experiment laid out on the Indian Agricultural Research Institute Farm at Delhi to study the effects of these two micronutrients in conjunction with certain major-element treatments on berseem are reported here. This experiment has been in progress on the same field for the past two seasons, namely, rabi (winter) 1949–50 and rabi 1950–51. The treatments are: main plot (1) superphosphate, (2) rock phosphate, finely ground to pass through a 100-mesh sieve, (3) 'Ammophos', all three to supply 80 lb. of phosphate ($P_2O_5$) each per acre, (4) ammonium sulphate to supply as much nitrogen as contained in treatment (3), and (5) control or no major element. Sub-plot: (1) boron to supply 5 lb. of borax per acre, (2) molybdenum as sodium molybdate to supply 1 lb. of molybdic oxide per acre, (3) boron and molybdenum (combined) as in (1) and (2), and (4) control or no micronutrient element. The design is 'split plot' with four replications. Net plot size is 1/60 acre.

The 0–9 in. depth sample of the soil, a loam, had the following characteristics: organic carbon 0·34 per cent, total nitrogen 0·04 per cent, available phosphate (Dyer) 0·034 per cent, base exchange capacity (milli-equiv./100 gm. soil) 16·60, pH 6·7.

Among the observations taken on several plant characters during the cropping seasons, nodulation was found to be significantly influenced by both boron and molybdenum. Before leaving the crop for seed, in 1949–50 four cuttings and in 1950–51 five cuttings of fodder were taken. The accompanying table gives the consolidated yield figures for the two seasons.

It is interesting to observe from these two years results that boron and molybdenum exercised a significant influence on the fodder, seed and 'bhusa' yields of berseem. Statistical analyses of the yields of individual cuttings have shown that in the first season the major element fertilizers were significant up to the third cutting; but in subsequent cuttings they failed to attain statistical significance, while the micronutrients started to become significant from the fourth cutting onwards. In the second season, however, while the major elements were found significant only up to the second cutting, the micronutrients proved significant in all the cuttings. A possible explanation for this would be that, since the requirements of micronutrients are small for normal healthy growth, the quantity present in the soil at the start was enough for the first few cuttings. But as more and more fodder was removed, they started to become a limiting factor, and thereafter the influence of fertilization with micronutrient elements became well pronounced.

The possibility of using boron and molybdenum as fertilizers in conjunction with phosphates to obtain increased yields of leguminous fodder and seed on soil types similar to those of Delhi is therefore indicated.

Further work is in progress.

## FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

### Saturday, January 17

BRITISH MYCOLOGICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 11 a.m.—Scientific Papers.

### Monday, January 19

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. Thomas Martin "The Faraday Manuscripts with a Word about Davy".

SOCIETY OF CHEMICAL INDUSTRY, CROP PROTECTION PANEL of the AGRICULTURE GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr B. A. Kilby. "The Biochemistry of Schradan".

### Tuesday, January 20

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (in the Chemistry Lecture Theatre, Royal College of Science, Imperial Institute Road, London, S.W.7), at 2.15 p.m.—Mr. R. A. Hamilton, Dr. A. B. Stewart and Dr. W. F. Raymond Papers on "The Manuring of Grassland".

ROYAL PHOTOGRAPHIC SOCIETY (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 3.30 p.m.—Mr. Bertram Sinkinson: "The Centenary of the Royal Photographic Society".

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENTS SECTION (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Measurements of Magnetic Permeability" (to be opened by Dr. A. J. King)

UNIVERSITY OF LONDON (in the Senate House, Malet Street, London, W.C.1), at 6 p.m.—Sir Godfrey Thomson: "The Geometry of Mental Measurement".* (Further Lectures on January 21 and 22.)

SOCIETY OF CHEMICAL INDUSTRY, CORROSION GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. M. Pourbaix "The Electrochemical Behaviour of Metals and Corrosion".

SHEFFIELD METALLURGICAL ASSOCIATION (in the Grand Hotel, Sheffield), at 7 p.m.—Annual General Meeting

SOCIETY FOR VISITING SCIENTISTS (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "The Physiology of Athletes" (Chairman Prof. A. V. Hill, F.R.S.; Speakers: Dr. C. G. Douglas, F.R.S., Mr Roger Bannister and Prof. A. Hemingway).

### Wednesday, January 21

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Prof. S. C. Harland, F.R.S.: "Plant Hormones" (Fernhurst Lecture)

ROYAL STATISTICAL SOCIETY, RESEARCH SECTION (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. D. V. Lindley: "Statistical Inference".

EUGENICS SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. J. D. Nisbet: "Family Environment and Intelligence".*

ROYAL METEOROLOGICAL SOCIETY (joint meeting with the BRITISH GLIDING ASSOCIATION, in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Discussion on "Fair Weather Cumulus".

ROYAL MICROSCOPICAL SOCIETY (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Annual General Meeting; Brigadier H. G. Smith: Presidential Address.

INSTITUTION OF ELECTRICAL ENGINEERS, EDUCATION DISCUSSION CIRCLE (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Discussion on "Some Difficulties in the Teaching of Electrical and Mechanical Resonance" (to be opened by Mr. C. T. Baldwin and Mr. J. C. Oakden).

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the LONDON SECTIONS of the SOCIETY OF CHEMICAL INDUSTRY and the INSTITUTE OF METALS, at University College, Gower Street, London, W.C.1), at 6.30 p.m.—Dr. A. C. Menzies: "Analysis of Metals by Spectroscopy".

WOOL EDUCATION SOCIETY (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7 p.m.—Prof. J. H. Nichols: "Improving the World's Wool Supply—The Role of the Biologist".

### Thursday, January 22

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. H. Cartan: "On the Calculation of Homotopy Groups".

MINERALOGICAL SOCIETY (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers

INSTITUTE OF RURAL LIFE AT HOME AND OVERSEAS (in Room H 301, Colonial Office, Church House, Great Smith Street, London, S.W.1), at 5.30 p.m.—Dr. F. N. Woodward: "The Uses of Seaweed".

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. F. Bergel: "Some Chemical Aspects of Normal Growth".* (Further Lectures on January 30 and February 6.)

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Prof. R. P. Linstead, F.R.S.: "Discoveries Among Conjugated Macrocyclic Compounds" (Pedler Lecture)

INSTITUTE OF WELDING, NORTH LONDON BRANCH (in the Fyvie Hall, The Polytechnic, Regent Street, London, W.1), at 7.30 p.m.—Mr. W. V. Binstead: "The Joining of Aluminium and its Alloys".

UNIVERSITY OF LONDON (in the Swanley Hall, Wye College, Wye, Ashford, Kent), at 8.15 p.m.—Mrs. Jacquetta Hawkes: "Our Primitive Beginnings".*

### Friday, January 23

ROYAL ASTRONOMICAL SOCIETY (joint meeting with the GEOLOGICAL SOCIETY, at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Geophysical Discussion on "The Magnetization of Rocks" (Chairman: Prof. C. E. Tilley, F.R.S.; Speakers: Dr J. M. Bruckshaw, Mr. A. F. Hallimond, Mr. J. Hospers and Mr. S. K. Runcorn).

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PRINCIPAL OF THE MID-ESSEX TECHNICAL COLLEGE, Chelmsford—The Chief Education Officer, County Offices, Chelmsford (January 23).

ASSISTANT SECRETARY (graduate of a British university, preferably in science or engineering, with some experience of industry) to the University Appointments Board—The Registrar, The University, Liverpool (January 24).

PHYSICIST—a knowledge of statistics desirable (Ref A.335/52A), and a BIOLOGICAL CHEMIST—preferred, but chemist with analytical experience or biologist with interest in chemistry acceptable (Ref. F. 808/52A), at the Ministry of Supply Tropical Testing Establishment, Port Harcourt, Nigeria, to assist in study of effect of tropical conditions on Service materials and equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No. (January 24)

PHYSICISTS at a Ministry of Supply Establishment, Aldermaston, for (*a*) research on methods of radiation measurements—knowledge of radiation physics desirable; (*b*) research on physical properties of radioactive materials—practical experience of electron diffraction work, or measurement of short time intervals using high speed oscilloscopes, desirable—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.336/52A. (January 24).

UNIVERSITY GRADUATE (preferably physiologist) as Research Student in the Birmingham and Midland Eye Hospital, Church Street, Birmingham, for work in connexion with hereditary ocular disease—The Secretary, Dudley Road Hospital, Birmingham 18 (January 24).

LECTURER IN INORGANIC AND PHYSICAL CHEMISTRY—The Principal, Heriot-Watt College, Edinburgh (January 20).

SENIOR LECTURER IN THE DEPARTMENT OF ELECTRICAL ENGINEERING, University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (February 1).

ASSISTANT ENTOMOLOGIST at the Wattle Research Institute, University of Natal—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (February 14).

ASSISTANT LECTURER IN GEOGRAPHY—The Secretary, London School of Economics and Political Science, Houghton Street, Aldwych, London, W.C.2 (February 20).

LECTURER or ASSISTANT LECTURER IN ZOOLOGY at the University, of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (February 23).

SIMON FELLOWSHIPS for advanced study or research in the Social Sciences—The Registrar, The University, Manchester 13 (March 1).

BIOCHEMIST (with a postgraduate degree in biochemistry and five years teaching experience) at the Lady Hardinge Medical College, New Delhi—The Secretary, Division 5A, Ministry of Health, Savile Row, London, W.1.

DIRECTOR AT THE NATIONAL COAL BOARD CENTRAL RESEARCH ESTABLISHMENT II, Isleworth, Middx, and a DIRECTOR OF EXTRA-MURAL RESEARCH, A (Physics, Chemistry and Engineering)—Sir Charles Ellis, National Coal Board, Hobart House, Grosvenor Place, London, S.W.1.

EXPERIMENTAL OFFICER at the Royal Aircraft Establishment, Farnborough, to co-ordinate technical data, development and approval of electronic valves for joint Services use—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.339/52A.

GRADUATES for positions in marine zoology and salmon research, in the fields of research on groundfish, salmon, marine mammals, herring and lobsters, and other commercial invertebrates—The Director, Newfoundland Fisheries Research Station, St. John's, Newfoundland, Canada.

HOSPITAL BIOCHEMIST (principal grade)—The Group Secretary, Southampton Group Hospital Management Committee, Bullar Street, Southampton.

LECTURER IN PHYSICS—The Secretary, Royal Technical College, Glasgow.

LECTURER IN SYSTEMATIC BOTANY AND ECOLOGY—The Secretary and Registrar, The University, Southampton.

METEOROLOGICAL ASSISTANTS by the Falkland Islands Dependencies Survey for service at Port Stanley—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.28136.E.

PRINCIPAL SCIENTIFIC OFFICER at a Ministry of Supply Experimental Flying Establishment, near Salisbury, to lead a section responsible for the complete design and proving of aircraft test instruments—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.341/52A.

SCIENTIFIC OFFICERS at Ministry of Supply Research Establishments in South-East England: EXPERIMENTAL PHYSICISTS (near Southend) with interest in light engineering or metallurgy (Ref. A. 279/52A), and THEORETICAL PHYSICISTS or APPLIED MATHEMATICIANS (near Sevenoaks)—experience in astrophysics useful for one post (Ref. A.280/52A)—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

# HUMAN RELATIONS IN INDUSTRY

IN order that the results of action taken concerning human relations in industry during the past few years might be assessed, and that consideration could be given to further steps that should be taken, the Ministry of Labour organized a conference held in London during March 18–20, 1952 (see *Nature*, 169, 872; 1952). The subjects on the agenda were grouped under four headings: (1) factors affecting the opportunity to work; (2) factors affecting the capacity of workers; (3) factors affecting wastage of man-power; (4) factors affecting the will to work. Matters concerning the physical environment, working methods and task organization were omitted.

Papers setting out the situation in each of these groups of subjects, as seen by the Ministry, were circulated in advance to the four hundred delegates who attended the conference. With them went a paper summarizing the findings of the various Anglo-American 'productivity teams' on human relations in American industry and one prepared by Sir George Schuster on conclusions from the projects sponsored by the Human Factors Panel of the Committee on Industrial Productivity, of which he was chairman.

The Ministry of Labour has now published a report on this conference*, which includes as appendixes the papers referred to. Sir George Schuster's paper is particularly welcome since, although condensed, it gives the first comprehensive report on the work of the Human Factors Panel, with a summary of the results of the group of researches which the panel sponsored.

The conference consisted of two kinds of meeting. There were general sessions, at the first of which the proceedings were opened by an address from the Minister; at these sessions speakers introduced the main groups of questions. In addition, Sir Cuthbert Clegg, president of the British Employers' Confederation, and Mr. T. Williamson, of the General Council of the Trades Union Congress, spoke on the paper on the reports of the Anglo-American 'productivity teams', and Sir George Schuster introduced his own paper. For the second type of meeting the conference broke up into groups, each group discussing one of the four main topics. These discussions were free and informal, and at their conclusion an outline of the report from the discussion group to the conference in general session was agreed upon and later prepared by a *rapporteur* for each group. The reports, which were considered in final sessions of the congress, are now published with a summary of the discussion on them.

At a fairly early stage in the conference, Mr. Lincoln Evans, general secretary of the Iron and Steel Trades Confederation, struck at the root of the problem of human relations in industry when he said: "We shall never get that relationship, each with the other, really right unless we can get the proper climate in industry; and we shall never get that unless industrial relations are based on something broader than the conception of two sides in industry".

---

* Ministry of Labour and National Service. Report of the Human Relations in Industry Conference, held at the Institution of Civil Engineers, London, March 18–20, 1952. Pp. vi+128. (London: H.M.S.O., 1952.) 3s. 6d. net.

Sir Cuthbert Clegg, president of the British Employers' Confederation, referred to the same point when he spoke of the vital necessity in our present economic situation of building up a greater sense of common interest and the development of mutual confidence between employers and work people. Sir Richard Snedden, also of the British Employers' Confederation, further supported Mr. Lincoln Evans's contention that industry should not be regarded as being made up of two sides. But as the conference proceeded, despite the efforts made by speakers from the employers' associations and the trades unions to avoid the use of the language of negotiation, it became clear that a good many of those present were still thinking of industry in terms of the conflict of interest between two sides. Perhaps it was this which led one speaker in the general discussion to protest that in a conference of this size it was not possible usefully to discuss many of the fundamental problems of human relations in industry.

The scientific aspects of the questions were considered by Sir George Schuster in his speech. His particular concern was to deal with the question: "How far and on what points is more knowledge required as a guide to the right handling of human factors, and what steps should be taken to obtain such knowledge and ensure its utilization ?". His general approach was governed by his belief that there is a real need for more systematic studies, but that such studies should be directed to meet known needs, and that the methods and research workers must inspire the confidence of those concerned with the practical conduct of industry, whose active interest and collaboration are essential. Although distinguishing five main groups of human problems in industry, Sir George emphasized the close relation between them and directed attention to the fact that circumstances outside the factory should not be ignored. He advocated, in fact, an ecological approach. Sir George contended that if 'scientific' were used in the wide Baconian sense, in which it included any orderly empirical study of the natural world, then the methods used for the study of human behaviour could fairly be described as scientific.

It must be admitted that the proceedings at the conference provided a good deal of evidence that the answer to Sir George Schuster's question: "Have we enough factual knowledge of what is happening in industry as a whole or are we putting forward opinions based on a narrow range of our own experience, or on intuition or preconceived ideas ?", is in the negative. The reason lies to some extent, at least, in the difficulty in identifying the real problem presented by a situation. This is shown in the confident assumptions sometimes made in industry on matters of morale and motivation, and also by the bewilderment aroused by behaviour which cannot apparently be logically explained. Failure to diagnose the nature of a problem from the symptoms tends to lead, if not to its dismissal, to its explanation in terms satisfying to the observer. The formulation of problems of human relations by those in industry in a fashion which permits their attack by scientific study is not easy; if, as is commonly the case, this consequently falls to the lot of the researcher, he has to convince both management and worker that he is attacking what is really a need for knowledge.

It was also clear that there has been a failure in communications between those who undertake scientific studies of human problems and those who are in the positions to make use of the knowledge acquired. Although some responsibility must be placed on the failure of the scientific worker to record his results in a fashion easy for the industrial manager to understand, there is a suggestion that in this field, too, industry is suffering from a lack of technologists who can translate the results of basic research into effective action.

Sir George Schuster had certain practical proposals for tackling some of the problems he raised. After referring to the discussions which had been in progress between the Department of Scientific and Industrial Research and the Medical Research Council about arrangements for the conduct of research in the human factor field, he suggested that the Ministry of Labour should set up a departmental advisory committee to watch the whole field, to identify problems and to keep in touch with research and progress. He advocated also an expansion by the universities, and particularly their social science departments, of studies of human problems of industry. The universities are particularly well placed, he suggested, to establish contact with industry in their area and to provide continuity of research, which is an essential requirement in the training of the new research workers who are needed if any expansion of activity in the study of human relations in industry is to be undertaken.

# SCIENTIFIC ACHIEVEMENTS OF M. V. LOMONOSOV

Russia's Lomonosov

Chemist, Courtier, Physicist, Poet. By Boris N. Menshutkin. Translated from the Russian by Jeannette Eyre Thal and Edward J. Webster under the direction of W. Chapin Huntington. (Published for the Russian Translation Project of the American Council of Learned Societies.) Pp. ix+208+5 plates. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1952.) 25s. net.

FROM time to time the scientific world has had its attention directed to the achievements of Mikhail Vasilyevich Lomonosov (1711–65), one of the many distinguished men of science of whom Russia is so justly proud. Born in a village on the coast of the White Sea, he studied science and metallurgy in Germany and returned to Russia in 1741, becoming a member of the Academy of Sciences in St. Petersburg, where he worked and taught until his death. Lomonosov was a grammarian, poet, historian and man of affairs as well as a scientist, and his collected works have been published by the Soviet Government. Although not mentioned by German historians of chemistry such as Kopp and E. von Meyer, he was quoted with appreciation by Demachy and by Hoefer (who thought the chemist and the poet were different persons). B. N. Menshutkin published an account of his work in 1904, and excerpts from his writings in Ostwald's "Klassiker" (No. 178) in 1910, and from these Lomonosov became better known outside Russia. Since then, B. N. Menshutkin has studied unpublished sources, but a comparison of the present book with an earlier study published in 1912 does not reveal much new material of importance. The book has been translated from Russian, and not very well; the names of Thomas Young and Fresnel, for example, appear as "Jong" and "Frenelle".

The main tendency of the book is the claim that Lomonosov anticipated many important discoveries, including those of Lavoisier, and that historians of science have denied him his true rights. Much of what is claimed for him (with an absence of reference to sources in many cases) is, however, not his property. A few examples may be given, and the editors have corrected more of the rather extravagant claims in the book itself. It is quite true that Lomonosov was in advance of his contemporaries in many respects, but a detailed examination of the claims made on his behalf does not substantiate some of them.

Although Lomonosov argued against the material nature of heat and regarded heat as a form of motion, this had been said long before by Francis Bacon, and the nature of the motion had been more correctly described by Bernoulli (who was in St. Petersburg) in 1738; he presented a kinetic theory of gases more correct than Lomonosov's. The latter assumed that the particles are rotating and that motion is transmitted from particle to particle by friction between their rough surfaces. Although Lomonosov, who had a good mathematical training, emphasized that chemistry should be developed on mathematical lines, this idea had been anticipated by Keill in 1708 and Freind in 1709, both of whom published a mathematical treatment of chemical changes in considerable detail, not to mention the book by Swedenborg of 1721 on the explanation of chemistry by geometry. The statement in the book that Lomonosov anticipated Lavoisier in stating the law of conservation of mass, together with the information that this law did not appear in books on chemistry until about 1860, will not bear investigation. Lomonosov had the idea that weight is not a true measure of mass and that weight could change in the same place if particles of an aggregate were separated so as to expose more surface to the action of gravity. He used this idea to explain the increase in weight of a metal on calcination in 1748, although a more correct explanation, that the increase is due to some material taken from the air, had been given by Mayow in 1674. It is true that Lomonosov says that "the air particles which always flow over the calcined body combine with it and increase its weight", but he explained the cause of the increase in weight in the way just given.

The claim that Lomonosov anticipated Lavoisier seems to be based on his criticism of Boyle's experiments on the increase in weight of tin on calcination, in which he said, in 1756, that Boyle should have weighed the sealed vessel before opening it and allowing the air to enter, and that Boyle's explanation that the increase in weight is due to the fixation of fire is invalid. But these statements had been made in 1679 by Cherubin d'Orléans. No details of Lomonosov's experiments on this subject survive, and in the few words of his conclusions from them he does not say that the increase in weight is due to the fixation of the air or part of the air, as Mayow had definitely said in 1674. Lomonosov had many good ideas, and if he had worked them out in detail he might well have made notable advances in science, but his duties as an academician and to some extent his irregular mode of life hampered his progress in scientific research. Yet others in even worse circumstances were not prevented from making discoveries.

It is clear from the book that Lomonosov, besides his theoretical ability, had also a keen interest in applied science; he set up a factory for making mosaics and in other ways was active in technology. He was undoubtedly a man of genius, but no service is done either to his memory or to the history of science by exaggerated claims that he anticipated important discoveries attributed to others. An impartial and objective study of his scientific work would be valuable and would receive sympathetic consideration; but it is to be feared that the exaggerated and, in many cases, unfounded claims made for him in the present book will create an unfavourable impression among those who have some knowledge of the facts of the history of science, and in this way will defeat the praiseworthy object of the author in making known the services of one of Russia's great men.

J. R. PARTINGTON

# THE ANATOMY OF CHROMOSOMES

**Allgemeine Pflanzenkaryologie**

Von Prof. Dr. Georg Tischler. Hälfte 2: Kernteilung und Kernverschmelzung. (Handbuch der Pflanzenanatomie, Allgemeiner Teil: Cytologie (Die Organe der Zelle), Band 2.) Zweite Auflage. Lieferung 1. Pp. 384. 58 D. marks. Lieferung 2. Pp. 385–720. 48 D. marks. (Berlin-Nikolassee: Naturwissenschaftlicher Verlag vorm. Gebrüder Borntraeger, 1951.)

IN 1922 Prof. G. Tischler, of the University of Kiel, published an account of the nucleus and the chromosomes in plants. This work was a section of the cytological part of an encyclopædic work on plant anatomy. The present two volumes are a new edition expanded to twice the original size and now illustrated with 466 text figures.

Prof. Tischler's first edition was fully in keeping with the standards of chromosome studies in plants at the time, standards which did not widely depart from those of plant anatomy. That is to say, it was descriptive and it gave weight to each author according to the mass of his publications. The new edition follows the same method. It never resists the temptation to be complete, and it is, in fact, most exhaustive. No controversy is so dead that it cannot here be revived and exhibited; no figure so doubtful or so hazy that it cannot here be accurately reproduced. Description, forgotten history and experimental data are set forth in what is no doubt a carefully considered order. But it is the order of plant anatomy translated to another level. Torn into the shreds of botanical subdivision, we find the dismembered unity of chromosome behaviour. The immediate interpretation we see described with utter impartiality as between the worst and the best. How wise the author is, in these circumstances, to leave the genetical and physiological interpretation out of the picture altogether.

Can such a book have any value? It is difficult to say. For, although there are perhaps twenty thousand references to names, with and without dates, in solid masses in the text, in the countless footnotes, and in the legends of figures, there is no list of references, no index and no contents. These will follow: but without them one can scarcely use the volume even as a work of reference.

Prof. Tischler's work will stand as a monument to his devotion, his industry, and his learning, the greatest which have ever come to fruition in this field of knowledge. Moreover, with the passage of time it will not diminish in value. A hundred years hence it will still show in the utmost detail how an attitude towards scientific research and a programme of scientific publication conceived in the nineteenth century could be faithfully continued in the middle of the twentieth century, thereby fulfilling the hopes of a generation which had passed away.

C. D. Darlington

# ANGLO-SAXON MAGIC AND MEDICINE

## Anglo-Saxon Magic and Medicine

Illustrated specially from the Semi-Pagan Text "Lacnunga". By J. H. G. Grattan and Charles Singer. (Publications of the Wellcome Historical Medical Museum, New Series, No. 3.) Pp. xii+234+7 plates. (London: Oxford University Press, 1952.) 28*s*. net.

This welcome and noteworthy addition to the scanty literature of Anglo-Saxon medical history is the combined work of two authorities, each eminent in his own sphere. The three-volume treatise by T. O. Cockayne, dated 1864–66, entitled "Leechdoms, Wortcunning, and Starcraft of Early England", was an important contribution, as also were J. F. Payne's Fitzpatrick Lectures of 1903, which were printed in the following year under the title "English Medicine in the Anglo-Saxon Times".

The late Prof. J. H. G. Grattan, an unrivalled expert in Early English language and literature, has collaborated with the leading medical historian of the present day, Prof. Charles Singer, in this book which, although smaller, is a worthy successor to Cockayne's and Payne's works. The first part, roughly one-half, of the book consists of a general survey of magico-medical practice in Anglo-Saxon England, by Prof. Singer, while the remaining part is the text, with translation on the opposite page, besides notes and a glossary, of "a magico-medical commonplace book" known as "Lacnunga", from the sole surviving manuscript in the British Museum, where it is listed as MS Harley 585. It seems to have been written, about the year A.D. 1000, by a 'leech' who was not of the priestly class, and who, as Prof. Singer remarks, "still dwells in the barbarian world of magic and hardly emerges therefrom". He begins with remedies for the head and eyes, and works his way downward in the time-honoured fashion. More than a hundred medicaments are mentioned, of vegetable origin for the most part, and not all of them can be identified. Among the animal remedies are fox's grease, hind's milk and crab's gall. Apparently more important than the remedies themselves are the incantations and exorcisms which must accompany their administration. One of these is the "Lorica" of Gildas, written in Ireland in the seventh century; there is also a spell against flying venom and a lay against elfshot, besides a Christian prayer for sore eyes.

The lays were to be sung over the medicines three times, and also "into the man's mouth and both ears". Nor is veterinary medicine neglected, as exemplified by a "rite for lost cattle" and a "charm for a sprained horse". Anglo-Saxon medicine appears to have little rational basis. According to Singer, it cannot be regarded "as an early stage of what is to become a great intellectual movement". It is, rather, "a final pathological disintegration of the great system of Greek medical thought". As examples of the charms may be mentioned the formula against malaria: "Flee, ye fevers, eighty-thousand angels are after you", and, for what are called seizures, the patient is advised to "take a hazel stick. Cut thy name thereon: fill the name with blood, and throw it over the left shoulder into running water, all silently".

While all those recipes are of interest to the medical historian as evidence of a decadent epoch in the progress of the healing art, the "Lacnunga" will probably be of greater value to the student of Anglo-Saxon than to the medical man. The medium by which the information is conveyed is at least as interesting as the facts themselves. The brief survey of the grammar contained in the last fifteen pages of the book may be of much value to students of linguistics, while the section dealing with "Semantics of Anglo-Saxon Plant-Names", giving the Anglo-Saxon, English, and Latin or Linnæan versions, forms a useful contribution to botany. The well-chosen illustrations are in themselves most informative, although it is perhaps unfortunate that the plates are not described in more detail. As is to be expected, the book is clearly printed and well produced.

Douglas Guthrie

# TEXT-BOOK ON RELATIVITY

## The Theory of Relativity

By Prof. C. Møller. (International Series of Monographs on Physics.) Pp. xii+386. (Oxford: Clarendon Press; London: Oxford University Press, 1952.) 35*s*. net.

This book is based on lectures given during the past twenty years by Prof. C. Møller, who is professor of mathematical physics in the University of Copenhagen. The preface describes it as a text-book for students in physics whose mathematical and physical training does not go beyond the methods of non-relativistic mechanics and electrodynamics. In arrangement the book follows a conventional pattern, slightly more than half being devoted to the special theory of relativity (including an introductory chapter with a historical survey) and the rest to the general theory, including a little on cosmological models (Einstein and de Sitter). It ends with some mathematical appendixes, an author index and a subject index which, like most subject indexes, might with advantage be fuller.

The style is clear and persuasive, and the author shows himself a skilful teacher in the way in which he dilutes the abstract with the particular. The mathematical machinery of tensor calculus is developed as the need arises, first for the special theory and then for the general theory. By the time the reader reaches the end of the book, he should have a good basic knowledge of the theory of relativity.

Ever since Minkowski published his famous paper on space and time in 1909 there have been two ways of looking at relativity—the old kinematical way, with constant reference to measuring-rods and clocks, and the Minkowskian way, in which the geometry of the four-dimensional continuum dominates. Prof. Møller definitely favours the former. He writes: "On the whole, the epistemological significance of the four-dimensional representation should not be exaggerated" and ". . . it must be emphasized that such a representation is quite formal". But of course he cannot get on without the space–time continuum, which is introduced in Chapter 4 with these cautionary remarks. There are even space–time diagrams on pp. 96, 152, 168; but they are queer diagrams—topologically incorrect representations of space–time, since the axes of ($x_1'$, $x_4'$) should be both inside (or both outside) the axes of ($x_1$, $x_4$) (cf. Fig. 1 in Minkowski's paper in "The Principle of Relativity", p. 78 (London: Methuen, 1923) ).

It seems to me that the book would have been better if Prof. Møller had been more sympathetic to the Minkowskian way of looking at things. When the head begins to swim with contracted rods and slowed clocks, the best antidote to confusion is a simple space–time diagram. Thus, in Chapter 8, which leads to the general theory of relativity through the "principle of equivalence", it would be good to recognize that the ends of a short rigid measuring-rod are simply adjacent world-lines with a constant normal separation between them. But having recognized this, and remembering how Herglotz's masterly treatment of rigid-body motions (*Ann. d. Physik*, 31, 393; 1910) restricts such motions, one cannot but be surprised at the simple dogmatism of Prof. Møller's treatment of that thorny problem—the rotating disk. If a second edition of the book gives him an opportunity to revise Chapter 8, I hope he will use it to give the reader a clearer idea of the concept of rigidity in relativity.

# EXPERIMENTAL EMBRYOLOGY OF BIRDS

## The Epigenetics of Birds

By Prof. C. H. Waddington. (Cambridge Biological Studies.) Pp. xvi+272. (Cambridge: At the University Press, 1952.) 35*s*. net.

PROF. C. H. WADDINGTON'S choice of the title of his new book is eye-catching and stimulating if for no other reason than that the word 'epigenetics' connotes in the minds of many embryologists a variable and changing spectrum of meanings. The author's rather broad use of this word as a name for "The science concerned with the causal analysis of development" may be somewhat surprising and unfamiliar to most embryologists, particularly, because such usage would seem to leave little room for ideas about the alternative, 'preformistic' causal aspects of development. Nevertheless, as one reads through the book it becomes apparent that 'epigenetic' is being used in a sense sufficiently broad to include both the interactive (inductive) and segregative (localizational) mechanisms of the developmental system. However, since Prof. Waddington's major concern is not the presentation of a general thesis of avian development (although his title might suggest it), we have little concern with the inevitable semantic difficulties which result from the use of the word 'epigenetics'.

The central purpose of the book, as the author states in the preface, has been to review the literature of experimental embryology of birds from 1930 up to about 1950. The book is fortunately much more than a simple review, for the author has frequently interjected his own evaluation and interpretations along with his description of the results and interpretations of the various workers in the field. Moreover, he has done this in a commendably objective and undogmatic way. His warnings about the making of interpretations of data accumulated by experimental methods and procedures that do not specifically warrant them should be accepted as a healthful shaking-up in our thinking about the mechanisms of bird development, regardless of whether all of us agree with his interpretations in particular instances (for example, interpretation of the organization of the unincubated *chick* blastoderm as a "single entity" on the basis of the results of studies of the unincubated *duck* blastoderm). One of the major contributions of the book is the comparison and critical evaluation of the many and sometimes conflicting results of the German, French, English and American workers—an analysis which has not been made previously in anything like as thorough a fashion.

The plan and order of presentation of the subject-matter follow in the main those of developmental chronology, beginning with an introductory chapter on technical methods and proceeding through a discussion of our knowledge of endoderm, primitive streak and embryo formation on to problems of organ system formation in later stages. The main emphasis has been devoted to such general problems as germ-layer interaction and primitive streak organizer (induction) activities. Special chapters deal briefly with a comparison of bird development with that of other vertebrates, biochemical mechanisms, feather development and pigmentation and with certain genetic effects and their phenocopies.

In the final and one of the most thought-provoking chapters in the book, the author has summarized the status of our knowledge of the "development of the epigenetic organization of the chick". This amounts in large part to a presentation and evaluation of our information about the regulative capacities of the early embryo. Among a number of valuable suggestions for future lines of attack is a most interesting one concerning the physiological mechanisms which underlie the processes of localization (or "segregation"). It is true that most of our information concerns the inductive (cell or tissue interactive) mode of differentiation—perhaps because this is most easily demonstrated experimentally—whereas almost nothing is known about the localizational or "segregative" mechanisms. Prof. Waddington suggests that "they offer to the embryologists of the future a problem perhaps even more important than that of the mechanisms of induction". It is obvious to all, however, that we still know very little about the actual mode of cell–cell interaction; for example, whether this is mediated by cell–cell contact and/or by diffusible substances remains an important problem in developmental physiology.

Embryologists will find this little book quite readable and provocative. It is well illustrated and contains a rather extensive bibliography. Prof. Waddington is to be congratulated for his efforts, which have produced a book both timely and valuable.

Nelson T. Spratt, Jun.

## Colloidal Dispersions

By Earl K. Fischer. Pp. vii+387. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1950.) 60s. net.

THE dust-cover of this book says that "Dr. Fischer's book is the first to cover both the theoretical and practical aspects of colloidal dispersions". This extraordinary statement becomes comprehensible when it is seen that the book is not, in fact, about colloidal dispersions at all, but deals with coarser systems. It deals, in fact, with the same field as J. M. DellaValle's "Micromeritics" (New York: Pitman Publishing Corporation, 1943), although there are considerable differences of emphasis and allocation of space to topics. A name for these very finely divided systems would be valuable, except that further divisions would continually arise: we might go from micromeritics to microteromeritics and microtatomeritics! From the point of view of free surface energy, the particle size is rigorous for spherical particles: for fine dispersions, all properties are highly dependent upon shape. 'Fine powders' or 'fine dispersions' would seem to be entirely adequate, without straining after an exactitude which does not and cannot exist.

"Colloidal Dispersions" is of little interest to academic workers but should be valuable to applied chemists. After an orthodox introduction of four chapters, rheological properties are discussed fully in seventy-seven pages, followed by thirty-four on surface-active agents in which pp. 225–227 contain an astonishing crop of peculiar statements. The remainder of the book describes grinding. The work is well documented by references to a wide variety of work and systems and forms an interesting chemical companion volume to Delavalle's more physical and fundamental book.

A. S. C. Lawrence

## Bird Migrants

Some Aspects and Observations. By Eric Simms. Pp. 212+16 plates. (London: Cleaver-Hume Press, Ltd., 1952.) 15s. net.

THE author declares that the purpose of his book is to introduce more people to the fascination of bird-watching and worth-while observations. It is now sixteen years since Landsborough Thomson's "Bird Migration" was published and became the standard work, so that there is room for a fresh account in view of the considerable advance in the study of bird navigation and orientation.

Perhaps the best chapters in this book cover a discussion on the latest theories, including the work by Griffin, Kramer and Matthews, and an exposition of seen and unseen migration. The author's experience as an airman enabled him to confirm that migration is usually at a level below the contours of the higher hills, and rarely indeed above three thousand feet. He describes the well-known cross-country migration, chiefly autumnal, between the Wash and the Severn, which he observed along the northern escarpments of the Cotswolds. East-coast migrants pour into the Wash southwards from Lincolnshire and westwards along the Norfolk coast, and are canalized along the Fen rivers south-westwards and follow the Avon to the Severn Estuary.

This is a promising first book. Unfortunately, it shows signs of hasty construction: the map of bird observatories omits the Lundy and Saltee stations, and there are too many vague generalizations with no supporting evidence. Thus: "migration and dispersal may happen not only amongst birds of different species, but amongst individuals of different age in the same species"; "The spotted flycatcher . . . in the mainland is not really uncommon except in some of the more remote groups of islands"; "At sea auks battle in the breakers to reach low-swimming herring and get tossed exhausted on the beach"; "the lonely and treeless Fair Isle, originally discovered by Dr. Eagle Clarke"; and the error made by Coward is repeated in stating that gannet and shearwater migrate overland in autumn, for "records cannot be invariably associated with weather". W. E. Kenrick, on the contrary, found by careful research into the meteorological records that the days preceding each inland recovery of these essentially marine birds were stormy, as a rule with some notable gale from a westerly quarter. These inland records proved to be of dead, dying or exhausted birds overtaken by weather and driven inland.

R. M. Lockley

## An Introduction to Acoustics

By Prof. Robert H. Randall. (Principles of Physics Series.) Pp. xii+340. (Cambridge, Mass.: Addison-Wesley Press, Inc., 1951.) 6 dollars.

THIS useful book, of intermediate degree standard, has been written mainly for students of physics, but it deserves to have a much wider range of readers, to include engineering students and others who may wish to specialize in communications and electro-acoustics. Indeed, a good knowledge of the basic principles of acoustics is absolutely essential to all who are engaged in the many practical applications of the subject.

The treatment given in the book follows a logical course, beginning with a study of vibrations as a preliminary introduction to the wave equations, and the importance of these topics to all branches of physics and engineering is stressed.

The mathematics used in the text should, in the main, be well within the compass of the students for whom the book is intended, except perhaps the complex notation used in Chapter 5, but even here the author gives only the essential material sufficient for the understanding of the text. The value of electrical analogies is fully recognized, and good use is made of such analogies in the solution of acoustical problems.

While giving a thorough account of the fundamentals of the subject, the author has not neglected the more popular and applied features, and has devoted considerable space to such topics as speech and hearing, loud-speakers, electronic devices, etc. In general, the book is quite a valuable contribution to the literature on acoustics.

## The Basuto

By Hugh Ashton. (Published for the International African Institute.) Pp. xi+355+17 plates. (London, New York and Toronto: Oxford University Press, 1952.) 35s. net.

THIS book gives a general, but accurate and comprehensive, account of the people of the wealthiest, and the largest in population, of the South African High Commission Territories. Basutoland came into being during the nineteenth century through the political genius of its chief, Moshesh; and through good fortune, and the warlike qualities of its people, managed to survive Zulu and Afrikaner attacks to emerge into the twentieth century as the largest native African State or tribe in southern

Africa. It takes its name from the Sotho or Suto, a group of southern Bantu people that extends from the Bechuanaland Protectorate southward to Basutoland. Thanks to the research of Prof. Schapera, anthropological attention has been mainly focused on the northern or Bechuana section; the publication of H. Ashton's book on the southern, and numerically far larger, section will help to redress the balance and, in addition, provide valuable comparative material and lead to a much fuller understanding of this southern Bantu people.

Some sections of the book, in particular the chapter on medicine, magic and sorcery, and the appendix on kinship marriage, will be of particular interest to social anthropologists; the greater part of it, however, is more general in character and will appeal to a far wider public. It is written by a man who is a competent administrator as well as an anthropologist, and who is thus able to give a direct and straightforward account of an African people in the twentieth century and to avoid the obscurity and abstraction which characterize the language and content of so many current anthropological monographs. In Chapter 15 on law, for example, Ashton describes the kind of law administered in the courts of Basuto ward chiefs immediately prior to the changes introduced by the British Government after the Second World War, quoting extensively from the court records of Chiefs Mosue and Bereng and giving us a study of what was actually happening in these particular courts. Such a chapter is much less likely to be coloured by the preconceptions of the field observer and his particular informants.

"The Basuto" is a book that has been worth waiting for and which should appeal to a wide range of readers. Its only regrettable feature is its price; it is a pity that the publicity section of the Commonwealth Relations or High Commissioner's Offices could not have subsidized its publication.

G. I. Jones

### Papers on the Basic Principles of Statistical Physics

By N. S. Krylov. Pp. 204. (Moscow: Academy of Science of the U.S.S.R., 1950.) 18 roubles.

PROBLEMS and arguments associated with the 'ergodic theorem' (or principle of continuity of path) have, from the times of Maxwell and Boltzmann to the present day, played an important part in establishing the kinetic theory. Decisive progress in the mathematics of these problems was made approximately twenty years ago, but scanty use has, so far, been made of this work for interpreting physical facts.

This book under review, which is written in Russian, was planned as a comprehensive treatise in which the recent mathematical results were applied to the statistical theories of physics. Owing to the premature death of the author, only some preparatory papers and single sections have been completed; but even the incomplete work is worth studying on account of the author's great knowledge of the mathematical aspects of every problem and its bearing on physics. The author's approach is to a remarkable extent independent of the traditional presentations of the subject; an example of his attitude may be found in the only paper he published in English (*Nature*, 153, 709; 1944).

Time series of observations of mechanical systems as compared with time series of random observations; specification of mechanical processes in terms of Markov chains; the calculation of relaxation times; the quantum mechanics of measurement with less than the greatest admissible accuracy: these and similar topics, which are relevant to the foundations of statistical thermodynamics and the stochastic theory of irreversible processes, are surveyed and utilized in original contributions. The author's work should—if translated—appeal to an appreciable number of English-speaking readers.

R. Eisenschitz

### Wild Flowers, Grasses, Ferns, Fungi, Trees

(Nature Field Series, 1.) Pp. vii+83.

### Birds and Wild Animals, including Marine Mammals

(Nature Field Series, 2.) Pp. vii+83.

### Insects and Spiders

(Nature Field Series, 3.) Pp. vii+72.

### Shore Life, Fish, Clouds and Weather

(Nature Field Series, 4.) Pp. vii+71.

By H. Trevor Jones. (London and New York: Frederick Warne and Co., Ltd., 1952.) 6*s*. 6*d*. net each.

THE succession of new books of natural history is almost as regular as the seasons of Nature herself. Some are primarily evocative and seek to attract the reader by appealing to the imagination and the emotions. Others are purely descriptive and attempt to win the intellectual interest of the reader. In this new series of Nature books for younger readers, H. Trevor Jones has set out both to stimulate enthusiasm and satisfy curiosity, and because of the attractive way in which the text and colour- and line-drawings are combined, can reasonably claim to have succeeded. The first book describes 145 species of wild flowers, six ferns, sixteen fungi and fifty-two trees. In the second book are descriptions of 163 species of birds and seventy-six species of other animals, including a few invertebrates. In the third, 152 species of insects and spiders are illustrated, while, in the fourth, Jones includes most of the common examples of fish and other forms of fresh-water and marine life in and around Britain; at the end of this book there is a useful section on clouds and weather, with additional information on tides and currents, stars and planets. In nearly every case the illustrations are conveniently set alongside the species to which they refer.

T. H. H.

### A Flower Book for the Pocket

By Prof. Macgregor Skene. Second edition. Pp. 378. (London, New York and Toronto: Oxford University Press, 1952.) 12*s*. 6*d*. net.

THIS little manual, a revised edition of a popular handbook, will provide a pleasant and instructive introduction to the study of British wild flowers. A simple system of classification is adopted in which eight groups are recognized; artificial keys are given to these groups and the natural families which comprise them. Further keys are provided to the genera in each family, and with the adequate and non-technical description of each species the beginner should have little difficulty in naming common wild flowers. More than five hundred plants are illustrated in colour, but the detail tends to be rather obscure. The author is to be commended for using, to a large extent, the nomenclature of the most recent British Flora.

# RAW MATERIALS OF LIFE*

By Dr. D. P. RILEY and Dr. U. W. ARNDT
Royal Institution

An egg contains within itself all that is necessary to make a live chick. Some air goes in through the shell and some carbon dioxide comes out; water vapour passes in and out; but apart from that, nothing is added or taken away. All the raw materials needed are already there and, given time and warmth, they are transformed into an organism capable of independent existence. These raw materials of life cannot but repay study, and, in fact, rapid progress has been made in the past few years in reaching an understanding of their complicated chemical structure.

One of the reasons why it is difficult to measure with certainty and precision the weight, size and shape of protein molecules is because many of them associate or dissociate to varying degrees in solution. A knowledge of molecular interaction in protein solutions would be of great importance to our understanding of processes occurring in the living cell and we are as yet only at the beginning of such knowledge. We have recently come to know, rather surprisingly, somewhat more about the intricate internal structure of protein molecules than we know about their grosser properties of shape and size. It is not too much to hope that a synthesis will soon be effected between the detailed chemistry of these molecules and their physico-chemical characteristics.

## X-ray Analysis

X-ray diffraction analysis has been used for many years in the study of proteins. It is not our present purpose to survey all that has been done in this field so much as to assess the relative value of various possible procedures in relation to the type of information it is desired to obtain.

The molecular weight of a 'globular' protein can be determined with considerable accuracy from a knowledge of the volume of the crystal unit-cell, its density and content of water or electrolyte solution. As is well known, the value derived in this way may be a multiple of the true molecular weight, but, apart from this factor, the degree of attainable precision is very great. The method is limited to those proteins which form large and sufficiently perfect single crystals. This elementary single-crystal procedure has been disappointing as a means of obtaining rapidly and unequivocally the actual molecular dimensions, although it is, in principle, capable of giving them with great precision. An alternative, and more generally applicable, method of studying molecular size and shape is afforded by the scattering of X-rays at low angles by solutions of proteins. In sufficiently dilute solutions, if no aggregation occurs, the observed scattering is a simple multiple of the scattering by a single molecule, averaged over all orientations. The derived quantity is a length, the 'radius of gyration', related to the moment of inertia, and does not uniquely define a volume or shape. However, by working under absolute conditions or by careful comparison with a standard protein of known molecular weight, the low-angle method provides molecular weights (or volumes) directly. Again, by the examination of concentrated solutions it is sometimes possible to estimate one or more molecular dimensions, if various simple assumptions are made. The combination of the three approaches should allow a fairly confident and rapid assessment of the shape and size of the molecule in favourable cases.

The forces acting between neighbouring protein molecules in concentrated solutions can, in principle, be measured by a process of Fourier inversion of the scattered X-ray intensity at low angles. The effect of changes in *p*H and ionic strength can be studied.

Many analogies exist between light-scattering methods and low-angle X-ray techniques, and the two procedures are, to some extent, complementary.

The most that one can hope to derive directly, concerning the molecular structure of proteins, from a diffraction experiment is the scattering function for a single molecule. This function, which is always real and positive or zero, is the conjugate complex of the 'Fourier transform' or 'diffraction picture' of the distribution of scattering matter within the molecule. The most direct way of observing the molecular scattering function would be to examine a partly-ordered assembly in which all molecules possessed exactly the same orientation, but random and relatively large intermolecular distances. This is achieved in part in some fibres and it may prove possible, although difficult, to produce suitable specimens artificially. The disadvantage of working with true crystals is that the regular arrangement gives rise to intermolecular interferences which obscure the pattern due to a single isolated molecule. Much ingenuity has been used in partially overcoming this difficulty, notably by the Cavendish Laboratory school, as described by Sir Lawrence Bragg in his Guthrie Lecture (*Proc. Phys. Soc.*, B, 65, 833; 1952). But it still remains the case that details of the intramolecular chemistry have yet to be deduced with certainty from work on single crystals.

## Molecular Models

If the strictly deductive procedure be abandoned, and the intellectually less satisfying (to the experimenter) procedure be adopted of working from hypothetical structural schemes, the problem becomes one of devising experimental approaches which can put such hypotheses to the test. A convenient method is to measure accurately the angular variation of intensity of monochromatic X-radiation scattered by an amorphous sample, with subsequent comparison with the intensity curve calculated from a given structural model. Alternatively, curves depicting the radial distribution of scattering matter may be the basis of comparison.

By the use of a proportional-counter spectrometer, intensity curves of this type can now be quickly obtained with an accuracy of about ± 2 per cent, and a survey of a number of proteins has been made*. All proteins, whether fibrous or corpuscular, seem to fall into three main structural types. For terminological convenience, these types will be called $\alpha$, $\beta$ and $\gamma$. $\alpha$-Proteins include the keratin–myosin–

---

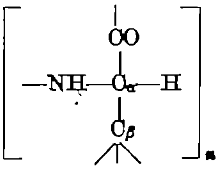
* Based on a Friday Evening Discourse entitled "The Chemistry of an Egg" delivered by Dr. D. P. Riley at the Royal Institution on November 7.

* The researches on protein structure in progress in the Davy Faraday Laboratory are being carried out with the assistance of Mr. W. A. Coates; publications describing the methods and results in detail are in course of preparation. Work has been greatly helped by grants from the British Empire Cancer Campaign.

epidermin–fibrinogen proteins of Astbury, also all the corpuscular proteins so far examined; silk fibroin is an example of the rarer β-proteins; and the γ-proteins constitute the collagen and gelatin group. Astbury's tripartite classification is thus of general applicability. It has further been shown that the only structural hypothesis so far studied which agrees with the scattering curves for α-proteins is Pauling, Corey and Branson's α-helix with about 3·7 amino-acid residues per turn in one coiled polypeptide chain. Here, the agreement is very close and the structure may be considered to be established beyond reasonable doubt. β-Proteins probably have fully extended polypeptide chains, while the configuration in the γ-proteins is not yet known.

A protein molecule consists of one or more main polypeptide chains:

$$(\text{—NH—CH}R\text{—CO—})_n \text{ or}$$



$$\left[\begin{array}{c} | \\ \text{CO} \\ | \\ \text{—NH—C}_\alpha\text{—H} \\ | \\ \text{C}_\beta \\ \diagup | \diagdown \end{array}\right]_n$$

to which are attached the side-groups, $R$, of relatively simple, and known, structure. The $C_\alpha$ carbon atoms at which these attachments occur are, in general, asymmetric and give rise to optical activity. The absolute configuration around the $C_\alpha$ atoms is now known and is described as *lævo* or L-. The above formula depicts it according to the usual convention: $C_\alpha$ is in the plane of the paper, the bonds to CO and $C_\beta$ are below, and those to NH and H above, this plane. The configuration being identical for all $C_\alpha$ atoms in proteins, there are only two ways of building an α-helix: a left-handed helix with the $R$ groups attached in one specific way, or a right-handed helix with the $R$-groups fixed in the alternative way. For brevity, these two structural types may be called $\alpha_1$ and $\alpha_2$, and their full descriptions are:

$$\alpha_1 = LH\ C_\beta 2\ \text{L-}C_\alpha\,;\quad \alpha_2 = RH\ C_\beta 1\ \text{L-}C_\alpha,$$

where $C_\beta 1$ and $C_\beta 2$ refer to the two alternative positions of the first carbon atoms ($C_\beta$) of the side-chains. The equivalent enantiomorphs, $\alpha_1'$ and $\alpha_2'$, can exist in synthetic polypeptides but not in natural proteins:

$$\alpha_1' = RH\ C_\beta 2\ \text{D-}C_\alpha\,;\quad \alpha_2' = LH\ C_\beta 1\ \text{D-}C_\alpha.$$

The α-type of protein structure can thus be divided, in principle, into two sub-types, $\alpha_1$ and $\alpha_2$, and there is no *a priori* reason why they should not both exist in Nature or even co-exist in one and the same protein molecule. By calculation, it can be shown that the amorphous scattering curves from $\alpha_1$ and $\alpha_2$ present recognizable differences, and the possibility therefore exists of distinguishing between them by experiment. Work along these lines is at an early stage, but it can provisionally be said that, while $\alpha_1$ seems to be the favoured structure in serum albumin, a mixture of $\alpha_1$ and $\alpha_2$ may exist in insulin. It is tempting to identify these with the $A$ and $B$ fractions of Sanger, and, indeed, the presence of a proline amino-acid residue (as in $B$) can be shown to impose the $\alpha_2$-configuration on the polypeptide chain in which it occurs. Examination of the separated fractions should settle the point.

Two methods are open to us for the examination of the side-chains by these X-ray scattering methods. One is to place the amino-acid residues along the main chain in the order found by Sanger by chemical means, and to calculate their effect on the intensity curve; the other is to perform a 'difference-Fourier' inversion of observed-minus-calculated intensity functions. The latter procedure gives a radial distribution curve corresponding to those parts of the structure which had been omitted from the first calculations, that is, principally, the side-chains. It has been shown in these ways that the effect of the side-chains on the scattering is not sufficiently specific to mask the dominating features imposed by the basic folding of the polypeptide chain.

In the case of insulin, the molecular structure would be almost completely determined if it were known how the $A$ and $B$ fractions are linked by cystine, —S—S—, bonds. The 'Courtauld' space-filling atomic models designed by G. S. Hartley and Conmar Robinson are of great help here; but a final unique solution still escapes us. One feature, however, which emerges from this sort of study is that neighbouring helices may well be skew to each other. If this is generally true, it would greatly complicate the detailed interpretation of Patterson series derived from single-crystal data.

Whether or not a given protein molecule has a unique structure is a matter for some doubt. Several workers have directed attention to the similarities between proteins and the silicate minerals. The possibility in proteins of 'isomorphous' replacement of 'non-specific' side-chains cannot be excluded and may even be probable. Such possibilities only lend weight to the argument that a detailed solution of the structure of a protein molecule is a matter for an integrated chemical and physical approach. On one hand, controlled degradation of the molecule with separation of the breakdown products, and, on the other, the use of an electronic computing machine in connexion with highly accurate intensity curves, would, in rational combination, lead to considerable advances in our understanding of the 'raw materials of life'.

## Survey of Structural Types

We should like to appeal for help from other centres in providing specimens for a survey of structural types in polypeptide molecules which we wish to undertake by the X-ray scattering method. It is not necessary in this sort of examination for the material to be crystalline; but adequate purity is important, particularly as regards freedom from inorganic salts. Purification could, of course, be done by us where necessary. Salt-free freeze-dried material is very suitable, as is any fine powder or amorphous mass. Fibrous material is less convenient. At present, the technique requires the use of about 100 mgm. of material to obtain the best results, but smaller quantities could be examined if need be.

We should be most grateful to any colleagues who might feel that they would like to contribute specimens to this survey. Perhaps they would, in the first place, write to us (at the Royal Institution, 21 Albemarle Street, London, W.1), giving details so that unnecessary trouble on their part could be avoided. If desired, the samples could be returned after examination, which should not normally affect them. It is desired to include in the survey natural proteins of all kinds (common and uncommon), denatured proteins or proteins which have been submitted to various chemical or physical treatments, synthetic polypeptides and natural polypeptides.

# PHYSICS OF THE HIGH ATMOSPHERE

A SESSION on the physics of the high atmosphere, under the chairmanship of Prof. A. M. Tyndall, was held on September 5 at Belfast by Section A (Physics and Mathematics) of the British Association. The meeting brought together four speakers who discussed this topic from different points of view, using what might be called the passive, the active and the direct observational, and the theoretical approach.

Historically, the scientific study of the earth's upper atmosphere evolved from ground observation of phenomena such as the auroræ and trails of meteors. It is remarkable, as became apparent from the paper by Dr. F. E. Roach (Naval Ordnance Test Station, Inyokern, Calif.), that this passive observational approach, when performed with modern, highly sensitive instruments, can still yield most valuable information about the properties of the upper atmosphere. An example of this type of approach has been the researches by Dr. Roach and his colleagues on the faint light emission from the night sky, known as the night air glow. They have been concerned mainly with the oxygen lines 5577 A. and 6300 A. which already formed the basis of Lord Rayleigh's classical work. It is interesting to note that the modern mean value for the intensity of $2 \cdot 8 \times 10^8$ quanta/sq. cm. column/sec. agrees rather closely with the value of $1 \cdot 8 \times 10^8$ obtained by Lord Rayleigh with his primitive equipment. Roach's measurements, conducted with photoelectric equipment under unusually good atmospheric conditions in the California desert, have led to the conclusion that the night air glow shows a maximum which occurs, on the average, near local midnight. On the basis of a detailed study of one night, Roach and Pettit[1] proposed that the isophot pattern of λ 5577 of the night air glow remains stationary with respect to the sun, while the earth rotates underneath.

Dr. Roach and his colleagues have tried to test this idea further by comparing the records of two stations—Cactus Peak, Calif., and Haute Provence, France—which are eight hours apart in terms of longitude. They have found that there appears to be some resemblance of the isophot patterns and sometimes of the maxima; but on the whole, the isophot patterns do not remain well preserved, indicating the influence of variable factors. When they attempt to measure the height of the emitting layer by means of triangulation methods, they find its altitude to be about 180 km. By other techniques, they have found altitudes in the neighbourhood of 250 km. All these values are in definite disagreement with photochemical theories which, in considering a purely static atmosphere, place the altitude of the emitting layer at approximately half that observed.

Another experimental approach of great interest was intended to establish the correlation between the intensities of the emission lines λ 5577 and λ 6300, a correlation which is to be anticipated since λ 5577 is a transition from the $^1S$-state of O I (which has a lifetime $\sim \frac{1}{2}$ sec.) to the $^1D$-state, and since λ 6300 is a transition from the $^1D$-state (which has a lifetime of $\sim 100$ sec.) to the $^3P$-state of O I. The comparison between the intensities of these two lines is most interesting: although generally about the same at the beginning of the evening, they show no relationship and even inverse correlations during the night. The correlation between λ 6300 and the total number of electrons in the $F$-layer, however, is very good. This again may be taken as an indication of the variability and instability of the very high atmosphere which becomes apparent because of the long lifetime of the $^1D$-state.

A more active approach to the study of the atmosphere has been reserved to this century. The probing of the upper layers by man-made radio signals commenced with the now famous experiments of Appleton and of Breit and Tuve. The values of the critical radio frequencies give immediately the concentration of electrons as a function of altitude. Mr. W. R. Piggott (Radio Research Station, Slough) discussed the vast amount of information which can be extracted from ionospheric reflexion data provided one looks at them in very special ways. Of particular interest is the influence on the upper atmosphere of tidal forces and their identification from the variations of electron density. There exists, for example, a definite twelve-hourly oscillation of the $F$-layer with a maximum height at local noon and midnight.

Expressing the variation of electron densities $N$ by the equation

$$\frac{dN}{dt} = q - f(N,X),$$

one can look separately at the agents which produce electrons ($q$), and other effects ($X$) which lead to the disappearance of electrons. It is found that this expression holds quite well in the lower ionosphere where the mean free paths are small and the layers are essentially in static equilibrium with respect to winds and oscillations. At the greater heights, however, the lifetime of the electrons increases as the collision frequency decreases, so that the atmosphere is no longer stable to large density changes.

These influences, which cause variations in the electron density, can be looked at in different ways. Mr. Piggott discussed, as an example, the dependence of $q$ on the sun. It is observed that the absorption in the $E$-region shows a maximum at noon and that during an eclipse the electron density in the $E$-region decreases very sharply. The upper layer, however, exhibits a completely different behaviour: for example, the formation of a new $F$-layer has been observed during a recent eclipse.

One of the most valuable features of ionospheric research is the possibility of geographical studies from data which come from fifty to sixty international stations distributed over the face of the earth. Such studies have shown the important influence of the earth's magnetic field on phenomena in the upper atmosphere: for example, the electron densities in the $F_2$-layer show a sharp dip ('cusp') in the immediate vicinity of the equator where the magnetic field is horizontal.

The high-altitude sounding rocket, the newest experimental technique for studying the upper atmosphere, was described by Dr. S. F. Singer (Office of Naval Research, United States Embassy, London). Rockets make possible measurements *in situ* by bringing instruments into direct contact with the upper regions of the atmosphere. They are unique, since they allow measurements of extra-terrestrial radiation, electromagnetic as well as corpuscular (for example, cosmic rays), before these radiations are modified or absorbed by the air. Of particular importance for the theory of upper atmosphere phenomena are measurements of the solar ultraviolet emission.

The results of rocket experiments of the past five or six years have, in many cases, confirmed conclusions already arrived at from sea-level observations. In many other cases they have provided more accurate and reliable data than can be obtained from the extrapolation of low-altitude measurements—for example, in determining the altitude distribution of ozone; and in a few cases they have given information which is completely new and sometimes unexpected—for example, the existence of gravitational separation of atmospheric constituents near the 70-km. level and the existence of a high-intensity electric-current stream above the magnetic equator.

Perhaps the greatest disadvantages of the rocket as a vehicle for high-altitude experiments are the high velocities and the short times spent in the upper atmosphere ($\sim 5$ min.). Rocket experiments involve other limitations which preclude their use for certain measurements and usually make them extremely difficult to perform from a technical point of view. The limited size and weight which are possible, the high accelerations and unpredictable motions, and the difficulty of recovering data, all enter into the design of an experiment. The rocket vehicles in present use in the United States are the small 'Aerobee', the altitude range of which is being extended to about 180 km., and the very large 'Viking' rocket, which has already achieved an altitude record of 220 km. and may be expected to go to much greater heights eventually. Both these research rockets were developed under the auspices of the United States Navy to take the place of captured German *V*-2 rockets with which high-altitude research in the United States was started in 1946.

The trend for the future of sounding rockets will be towards higher altitudes; but for certain experiments the present altitudes are already sufficient, and the greatest handicap consists of the fact that rocket experiments, allowing for but a few minutes of observations, can only be made infrequently and, in general, only at a particular location. In this connexion Dr. Singer reflected on the probable state of ionospheric research or of geomagnetism, were those sciences similarly confined. In his opinion, the development of a rocket capable of long-time observations over a wide geographical range would overcome these fundamental limitations of sounding rockets. Such a rocket might even represent an economical solution of the problem when one considers the expense at present involved in the instrumentation and launching of some dozens of 'Aerobee' rockets. In order to set up an observing station to last at least for a few days, it would be necessary, of course, to place it into an orbit where it could exist for some time as an artificial satellite of the earth. Such a satellite rocket should be viewed mainly as an observatory for studying variations in the emission of solar radiation, both ultra-violet and X-ray; of solar corpuscles; and of the solar component of cosmic rays. Such studies may well constitute the important link necessary for a more complete understanding of the physics of the sun and of the sun's influence on the earth's atmosphere.

The theorist of the upper atmosphere is constantly faced with the necessity of effecting a reconciliation between the physical theories and vast amounts of sometimes uncertain experimental data, together with inferences about the solar spectrum. As Prof. D. R. Bates (Queen's University, Belfast) put it: "It has been said that it is comparatively easy to write a paper about any single aspect of the upper atmosphere, but practically impossible to write consistently about several". As an example he mentioned the problem of the temperature of the exosphere. This temperature can be computed from the known rate of escape of helium gas; one may also ask how this high temperature is maintained in the face of cooling by conduction and also by infra-red radiation from the $^3P$-state of O I. If one invokes for this purpose an increase in the assumed ultra-violet emission of the sun, this in turn requires a re-interpretation of ionospheric observations.

One of the most fruitful lines has been the photochemical theory of the upper atmosphere, which seeks to account for chemical changes through the action of solar ultra-violet radiation. It has been particularly successful in explaining the formation and distribution of ozone. It has been used by Prof. S. Chapman and others to calculate the dissociation of the oxygen molecule; they have shown that, in the region above the 100-km. level, molecular oxygen must be completely broken down into atoms. The position concerning nitrogen is still the subject of controversy: on one hand, auroral spectra suggest that the molecular form is still abundant, even at altitudes of 500 miles; but, on the other hand, there is some observational evidence that dissociation into atoms is significant even at an altitude of about 100 km. Attempts have been made to calculate the relative abundances of the two forms of nitrogen at various levels from the rates of the various photochemical processes likely to be of importance, but these are so complicated that success has not yet been achieved. The time for equilibrium dissociation is found to be of the order of a few years, so that the local equilibrium depends very much on the dynamics of the atmospheric region. Hence any predictions based on static atmospheric models are likely to be incorrect. Similarly, the problem of chemical reactions of nitrogen is extremely difficult. For oxygen all the other gases present are inert, so that only four or five chemical reactions need be considered, whereas in the case of nitrogen molecules the oxygen enters into combination, thus leading to about thirty different chemical reactions.

Already the first measurements on the upper atmosphere have destroyed the old theory which pictured it in a state of hydrostatic equilibrium with hydrogen and helium predominant at the higher levels. Certainly new experimental findings will stimulate the theorist to try out new ideas, but Prof. Bates also reminded those present at the meeting that, in the case of the atmosphere, Eddington's famous advice, "never believe any observational results until they are confirmed by theory", is not without relevance.

The overall impression gained from these talks is that many of the fundamental features which affect the atmosphere are at present either unknown or roughly inferred. A particular point at issue is the ultra-violet and X-ray spectrum of the sun. Some rocket experiments have been made which have succeeded in measuring the spectrum down to about 2000 A. and have also obtained semi-quantitative information in some regions of the far ultra-violet and even X-radiation[2]. However, the technical difficulties of doing this work are very great. Besides this, it is known from the examination of ionosphere records that there exists a great variability in the ultra-violet emission from the sun, so that isolated rocket measurements may not give a representative picture of average conditions of the sun and of the range of these conditions. It seems more likely that once one can relate certain features of the ionosphere with solar ultra-violet emission, one may be able to observe the sun by following changes of the ionospheric layers.

The position is more satisfactory with respect to the structure of the atmosphere. Recent rocket measurements[3] have given values of the temperature, density and pressure up to altitudes of about 220 km. The values up to 150 km. can be considered to be well established and are in rather good agreement with values deduced from meteor observations. In regard to the chemical composition of the atmosphere, first definite evidence that gravitational separation takes place near an altitude of 70 km. has been obtained from stratospheric air samples recovered with rocket-borne sampling-bottles and analysed in Prof. F. A. Paneth's laboratory[4]. It now seems important to confirm these results up to higher altitudes; there is every hope that present techniques can be extended to obtain measurements up to about 120 km. In this connexion Prof. Bates emphasized the great importance of human activity in affecting the abundance of certain minor gases in the atmosphere. He even suggested a new technique, namely, that of deliberately introducing certain rare components, like sodium, into the upper atmosphere in order to observe their photochemical reactions. One might expect rather large luminosities to arise from the conversion of stored-up photochemical energy by only small quantities of sodium.

In the discussions following the papers, Prof. K. G. Emeléus (Queen's University, Belfast) mentioned very briefly the relation of laboratory experiments on gas discharges to actual phenomena in the upper atmosphere. The great stumbling-block in laboratory experiments are the walls of the discharge tube and their effects on the phenomena to be studied. Dr. Singer brought out the point that in many cases the upper atmosphere itself provides a laboratory in which one can study certain physical phenomena. For example, the region of very high electrical conductivity found in the *E*-layer at the magnetic equator[5] strongly suggests the existence of 'boundaries', which could effectively be established by the horizontal magnetic field.

Some important conclusions on the state of the atmosphere above about 150 km. emerged from these stimulating discussions on the physics of the upper atmosphere. Below this level the atmosphere can be thought of as being in a static state; but above this altitude a dynamic picture seems to be necessary, since the static model no longer describes the actual phenomena. This transition was brought out especially clearly by the ionospheric results presented by Mr. Piggott; the differences between the lower and upper regions of the ionosphere are immediately apparent if one draws 'isophots' over the earth's surface: the *E*-layer shows a normal distribution, while the *F*-layer does not. This was emphasized further by the disagreement between photochemical theory and the observations of Dr. Roach, particularly the striking discrepancy in the height of the emitting layers. This non-equilibrium, dynamic condition above the *E*-layer in certain respects resembles tropospheric weather. It is a consequence, it was thought, of the long mean-free-paths, low collision probabilities and consequent long lifetimes of certain states, the low thermal capacity of the upper layers, and also the variability of the ultra-violet emission of the sun. In this connexion the value of isolated observations by rockets above altitudes of 200 km. appears doubtful. It would seem much more necessary to adopt the synoptic approach, as is used for ionospheric studies, particularly with regard to the study of ultra-violet radiation from the sun.

# DIFFERENTIATION OF VITAMIN $B_{12}$ ACTIVE COMPOUNDS BY IONOPHORESIS AND MICROBIOLOGICAL ASSAY

FROM THE NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING, UNIVERSITY OF READING

## Ionophoresis

By Dr. E. S. HOLDSWORTH

SINCE the isolation of vitamin $B_{12}$ and other members of this group, several other compounds have been detected, related to but not in the cobalamin series. Wijmenga[1] isolated from pig fæces a crystalline substance he called vitamin $B_{12m}$; Ford and Porter[2] found vitamin $B_{12}$-like factors *A*, *B* and *C* in calf fæces, and isolated factor *A* in crystalline form; workers at Glaxo Laboratories (Lester Smith, private communication) have isolated in a fermentation process a factor, to our knowledge, identical with factor *B*; Pfiffner *et al.*[3] obtained pseudo-vitamin $B_{12}$ and pseudo-vitamin $B_{12b}$ from a rumen anaerobe; Lewis *et al.*[4] reported the presence of vitamin $B_{12f}$ in rat fæces; Hausmann[5] has described further compounds, and other vitamin $B_{12}$-like compounds are being discovered. Dr. Pfiffner and Dr. Wijmenga kindly put at our disposal specimens of their compounds for comparison with those isolated by us.

In a study of these factors by paper chromatography with a number of different solvents, we noted that several had almost identical $R_F$ values. Thus factor *A*, vitamin $B_{12m}$ and the pseudo-vitamins $B_{12}$ and $B_{12b}$ could not be separated with the solvents usually employed. The ionophoresis of these substances on paper was then examined. In veronal/acetate buffers between pH 3·0 and 9·0, there was little advantage in the use of ionophoresis, since only factors *B* and *C* have appreciable mobility under these conditions, and these are easily distinguished chromatographically. However, the interesting observation was made that several of the factors when subjected to ionophoresis on paper using 2*N* acetic acid (pH 2·1) gave rise to multiple zones. Fig. 1 shows the findings after ionophoresis for 16 hr. at a potential gradient of 8 volts per cm. The atmosphere in the apparatus contained hydrogen cyanide in an attempt to retain the substances in the cyano-form, and the vitamins were revealed by the bioautographic technique described elsewhere[6]. Factor *A* and vitamin $B_{12m}$ were alike in giving one main zone of the same mobility, accompanied by four

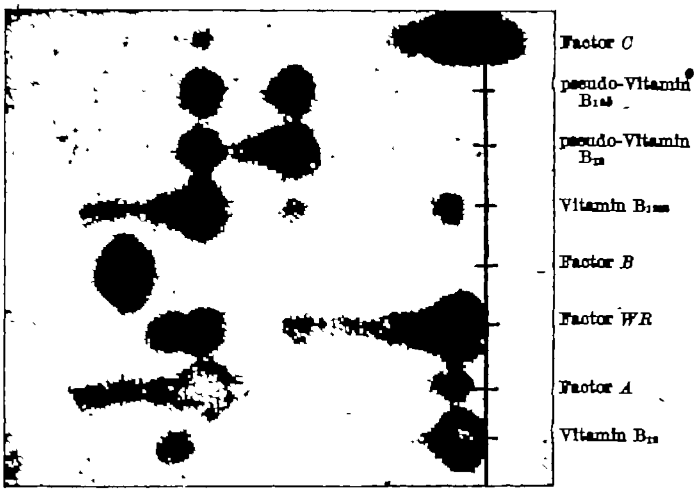

Fig. 1. Bioautograph using *Bact. coli*. Ionophoresis in 2*N* acetic acid for 16 hr. at 270 V.

others. Pseudo-vitamins $B_{12}$ and $B_{12b}$ each gave rise to two zones. A disadvantage of the bioautographic method for detecting activity is that the size of the bacterial growth-zone is proportional to the logarithm of the concentration of active substance, so that substances present only in traces are revealed; this explains why two spots were obtained from vitamin $B_{12}$, the more mobile spot probably representing vitamin $B_{12b}$ formed by loss of the cyano-group. To avoid this complication, the substances were used in larger quantities (50–500 µgm.) to give visible pink spots, the concentration of acetic acid was reduced to 0·5 *N*, with 0·01 per cent potassium cyanide, and finally, the apparatus was protected from strong light. Under these conditions, vitamin $B_{12}$ gave only one pink zone of zero mobility.

Factor *A* contained as major component a substance of mobility $3 \cdot 9 \times 10^{-5}$ cm.$^2$ V.$^{-1}$ sec.$^{-1}$ as calculated by the method described by Kunkel and Tiselius[7], together with three minor components the positions of which suggested that they could be due to the presence in factor *A* of vitamin $B_{12}$, pseudo-vitamin $B_{12}$ and factor *B* (Fig. 2, p. 151). With pseudo-vitamin $B_{12}$ and pseudo-vitamin $B_{12b}$ the major zone, of mobility $1 \cdot 5 \times 10^{-5}$ cm.$^2$ V.$^{-1}$ sec.$^{-1}$, was preceded by a pink spot of the same mobility as factor *A* (Fig. 2). Pseudo-vitamin $B_{12b}$ gave a third zone, brown in colour, of zero mobility and microbiologically almost inactive. By eluting each of the zones obtained from factor *A* and from the pseudo-vitamins $B_{12}$ and $B_{12b}$, and subjecting each to repeated ionophoresis, the materials were obtained as single spots of the presumably pure substances. Vitamin $B_{12III}$ was not available in sufficient amount to allow the separation of a visibly pink substance, but since it gave the same pattern of spots as factor *A* on the bioautograph (Fig. 1), there is reason to believe that vitamin $B_{12III}$ contains the same major component as factor *A*, with pseudo-vitamin $B_{12}$, vitamin $B_{12}$ and factor *B* as impurities. The same considerations suggest that factor *WR* obtained by Wijmenga[1] from ox liver is a mixture (Fig. 1). In cyanide extracts of the natural materials examined, we have so far been able to distinguish five substances having the following mobilities in 0·5 *N* acetic acid expressed as cm.$^2$ V.$^{-1}$ sec.$^{-1}$: factor *A* (vitamin $B_{12III}$), $3 \cdot 9 \times 10^{-5}$; factor *B*, $5 \cdot 0 \times 10^{-5}$; factor *C*, $- 1 \cdot 4 \times 10^{-5}$, that is, moving towards the anode; pseudo-vitamin $B_{12}$, $1 \cdot 5 \times 10^{-5}$; and vitamin $B_{12}$, with zero mobility.

An observation of practical importance made during the ionophoresis of the vitamin $B_{12}$-like substances is that ionophoresis may be applicable to other substances carrying very small electric charge. When the mobilities of the factors were compared in 0·5 *N* acetic acid and 0·1 *M* sodium acetate/hydrochloric acid buffer of the same *p*H, it was found that the mobilities in the buffer mixture were only about a third of those in acetic acid. If the acetic acid was made 0·2 *M* with respect to sodium chloride, sulphate or phosphate, without changing the *p*H of the solution, mobilities decreased. The polyvalent phosphate had the most effect, reducing mobilities almost to zero. Thus it is probable that the ionic strength of the conducting medium is the important factor, since it is known that a charged particle in solution acquires an atmosphere of oppositely charged ions, which have a retarding effect on the particle, the retarding effect increasing with increase in ionic strength[8]. Weak acids other than acetic (for example, phenylacetic and boric acids) can be used, and with a 0·5 *M* solution of boric acid, separations of the vitamin $B_{12}$-like substances can be obtained at a *p*H of 4·5 that cannot be obtained in the presence of strong electrolyte. Conducting solutions of low ionic strength must be used with caution, since they have very little buffering capacity and therefore the substances examined should be free from salts. Moreover, with increasing *p*H values, electro-osmosis becomes more marked and is a complicating factor in obtaining adequate separation.

## Microbiological Tests

By J. E. FORD

We have shown that certain of the vitamin $B_{12}$-like compounds are differently active for different test organisms (cf. Ford[9]). In addition, each substance has different activities, relative to that of vitamin $B_{12}$, for the individual test organisms used in different assay techniques. The ratios of these different vitamin $B_{12}$ activities are characteristic for each of the substances examined, and it was therefore possible to design differential assay procedures to provide evidence for their identity or otherwise.

*Tests with Bacterium coli.* A mutant of *Bacterium coli* requiring vitamin $B_{12}$ was used in the tube-assay technique described by Burkholder[10]. The basal medium was modified by substituting thiomalic for thioglycollic acid.

Tests were also carried out using this organism in the cup-plate technique perfected by workers at the Glaxo Laboratories[11–13] using the same basal medium as in the tube assays.

*Tests with Lactobacillus leichmannii* ATCC 4797. With this organism we have used the method and medium described by Skeggs *et al.*[14], modified only in that the *p*H of the medium was adjusted to 5·5. Nucleotides were omitted from the medium; tubes were steamed for 30 min. before inoculating, and incubated for 60 hr. at 35° C.

*Results.* In Table 1 are set out results of differential assays of a number of vitamin $B_{12}$-active compounds. It is evident that factor *A* and vitamin $B_{12\text{III}}$ have very similar microbiological activities, as have also the pseudo-vitamins $B_{12}$ and $B_{12b}$. The two groups of compounds, however, are clearly different in their microbiological properties. Factors *B* and *WR* are different from each other and from the other two groups of substances. The results presented for factor *C* are only tentative, since this compound has not yet been prepared in pure form in significant amounts, and tests were carried out on a relatively crude concentrate. Optical densities at 361 mμ are included as an indication of the concentrations of the various substances.

Table 1. RELATIVE VITAMIN $B_{12}$ ACTIVITIES OF DIFFERENT COMPOUNDS, MEASURED BY DIFFERENT ASSAY TECHNIQUES
Results are expressed in terms of the activities measured by the *Bacterium coli* tube-assay, given as 100 in each instance

| Substance | Relative optical densities* at 361 mμ | *Bact. coli* tube-assay | *Bact. coli* plate-assay | *Lacto. leichmannii* tube-assay |
|---|---|---|---|---|
| Vitamin $B_{12}$ | 100 | 100 | 100 | 100 |
| Factor *A* | 204 | 100 | 267 | 83 |
| Vitamin $B_{12\text{III}}$ | 238 | 100 | 282 | 91 |
| Pseudo-vitamin $B_{12}$ | 560 | 100 | 700† | 293 |
| Pseudo-vitamin $B_{12b}$ | 525 | 100 | 525† | 280 |
| Factor *WR* | 310,000‡ | 100 | large 'fuzzy' zones | 40,000‡ |
| Factor *B* | 1,350§ | 100 | 770 | 0·38 |
| Factor *C* | not known | 100 | 8,500 | 13·9 |

* Values are only very approximate. In some instances the amounts available for measurement were very small.
† Responses were markedly non-linear.
‡ This high figure reflects the low activity of factor *WR* in the *Bacterium coli* tube-assay.
§ The absorption maximum of this compound is, in fact, at 355 mμ.

In Table 2 are shown results obtained in the differential assay of certain components of these 'parent' compounds, obtained by ionophoresis in 0·5 *N* acetic acid as described in the first part of the paper.

Table 2. RELATIVE MICROBIOLOGICAL ACTIVITIES OF COMPONENTS OF VARIOUS VITAMIN $B_{12}$-LIKE COMPOUNDS OBTAINED BY IONOPHORESIS

| 'Parent' substance | Component | Ionophoretic mobility in 0·5 *N* acetic acid ($\mu \times 10^5$) | *Bact. coli* tube-assay | *Bact. coli* plate-assay | *Lacto. leichmannii* tube-assay |
|---|---|---|---|---|---|
| Factor *A* | Spot 3 | 3·9 | 100 | 274 | 64·4 |
| Pseudo-vitamin $B_{12}$ | Spot 2 | 3·9 | 100 | 264 | 68·0 |
| Pseudo-vitamin $B_{12}$ | Spot 1 | 1·5 | 100 | 1,400* | 425 |
| Factor *A* | Spot 2 | 1·5 | 100 | 1,000* | 375 |
| Factor *B* | Factor *B* | 5·0 | 100 | 580 | <0 3 |

* Responses were markedly non-linear

It is clear that the major component of factor *A*, its 'spot 3', is not distinguishable by these tests from the minor component of pseudo-vitamin $B_{12}$, its 'spot 2'. In the same way, the major component of pseudo-vitamin $B_{12}$, its 'spot 1', is not distinguishable from a minor component of factor *A*, its 'spot 2'.

There is evidence from bioautographs that factor *WR* contains, in addition to its several vitamin $B_{12}$-active components (see Fig. 1), a further substance inhibiting the growth of *Bacterium coli*. The presence of this inhibitor no doubt explains the low activity of the compound for this test organism.

# Occurrence of the Various Vitamin $B_{12}$ Active Compounds

## By J. E. FORD, DR. E. S. HOLDSWORTH, DR. S. K. KON and DR. J. W. G. PORTER

THE ionophoretic and microbiological findings just described show that compounds formerly accepted as pure were not, in fact, pure. We interpret our findings as proof that factor *A* and vitamin $B_{12\text{III}}$ are not pure substances, but that they contain the same major component. Similarly, pseudo-vitamins $B_{12}$ and $B_{12b}$ owe their activity to a common major component, different from that of factor *A* (or vitamin $B_{12\text{III}}$), and to factor *A*. The lower microbiological potencies of pseudo-vitamin $B_{12b}$ are probably due to the presence in it of a third component detected by ionophoresis (Fig. 2) that has little activity for micro-organisms.

Vitamin $B_{12f}$[4], from our experience with vitamin $B_{12}$-active compounds from rat fæces (see below), may possibly be a mixture of factor *A* and pseudo-vitamin $B_{12}$. Factor *WR*[1] from beef liver contains factor *A*, pseudo-vitamin $B_{12}$ and vitamin $B_{12}$, and is interesting in that it indicates that factors other than vitamin $B_{12}$ can appear in small amounts in the liver of ruminants (cf. Ford *et al.*[13]). Further, we have found that the vitamin $B_{12}$ activity of cow urine is largely contributed by substances other than vitamin $B_{12}$ (unpublished).

We have estimated the relative amounts of the different vitamin $B_{12}$-active compounds in the fæces of calves, rats and rabbits. Chromatography of extracts of all these materials showed a broadly similar distribution of activity: the main component being fraction *A* with small contributions from factors *B*, *C* and vitamin $B_{12}$. The fraction *A* component from each extract was repeatedly chromatographed until it appeared homogeneous: subsequent ionophoresis in 0·5 *N* acetic acid separated the apparently homogeneous fraction *A* component from calf fæces into factor *A* with some pseudo-vitamin $B_{12}$ and a trace of vitamin $B_{12}$; the fraction *A* component from rat fæces yielded approximately equal amounts of factor *A* and pseudo-vitamin $B_{12}$; and that from rabbit fæces yielded factor *A* and only a trace of pseudo-vitamin $B_{12}$.

In the light of these findings we now consider that the vitamin $B_{12}$-activity for micro-organisms of extracts of gut contents and fæces, prepared in the presence of cyanide, is contributed in varying proportions by the following five substances: factors *A* (vitamin $B_{12\text{III}}$), *B* and *C*, pseudo-vitamin $B_{12}$ and vitamin $B_{12}$ itself. In natural materials these compounds may exist in both free and combined forms (see also ref. 5).

The facts that these compounds act as alternative growth-factors for several micro-organisms, and that in extracts of *Bacterium coli* cells grown in a peptone medium all five compounds are present, suggest their close structural similarity.

The difficulty of separating these vitamin $B_{12}$-like compounds in a pure state by chromatography, and the relative ease with which chromatographically homogeneous though impure compounds crystallize (for example, factor *A*, vitamin $B_{12\text{III}}$ and pseudo-vitamin $B_{12}$), may give rise to a number of spurious new 'substances' with similar though not identical properties. Such new 'substances' are likely to be isolated during the fractionation of the vitamin $B_{12}$ activity of natural materials unless ionophoretic

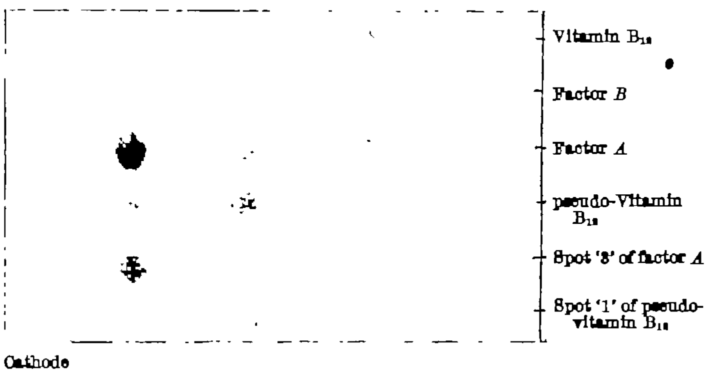

Fig. 2 Visibly pink amounts of the factors after ionophoresis in 0·5*N* acetic acid for 16 hr. at 270 V. Movement of vitamin $B_{12}$ was due to electro-osmosis

techniques, which are more selective than those of chromatography, are used for their resolution.

As these vitamin $B_{12}$-active compounds are formed by microbial synthesis in the rumen or in the large intestine or in both, it is probable that the relative amounts of each that appear in gut contents depend on the composition of the microbial flora. This is known to be, to some extent, governed by the composition of the diet, so that even within one species it is likely that the relative amounts of each of these factors will vary with the nature of the diet.

We should again like to thank Dr. Pfiffner and Dr. Wijmenga for their generosity in allowing us to examine their compounds, and to publish our findings. The interpretation of the results is solely ours ; the conclusions may not represent the views of Dr. Pfiffner or Dr. Wijmenga and do not bind them in any way. [Dec. 3.

# OBITUARIES

## Prof. M. G. Evans, F.R.S.

PHYSICAL chemists all over the world will have learned with sorrow of the untimely death of Prof. M. G. Evans. A graduate of the University of Manchester, Evans was appointed to the staff of the University in 1926, and after spending a year with a Rockefeller fellowship at Princeton, he was appointed to the chair of inorganic and physical chemistry in the University of Leeds in 1939. While at Leeds he established an international reputation for his work on the fundamental processes occurring in chemical reactions, and was elected a Fellow of the Royal Society in 1947. In 1948 he returned to Manchester to the chair of physical chemistry, and had already established a flourishing research school there when his scientific work was so tragically brought to its close.

Evans occupied a unique position in English physical chemistry. His versatile and flexible mind endowed him with a remarkable capacity for grasping the essentials of any scientific problem which was presented to him. All those who had the opportunity of working with him were astonished at his ability to state their problems for them in clear, exact and illuminating language, and there was no better cure for the all too common complaint of 'getting stuck' than to go and have a chat with 'M. G.', as he was known to all his friends. Evans's inspired common sense was the secret of his scientific success, both in his own work and in guiding the research of others.

Evans was one of the early pioneers of the transition state theory, applying it to quite complicated chemical reactions ; and it was largely his inspiration which led to the modern theory of unimolecular reactions. His work on the initiation of polymerization led to important technical advances, and in more recent years he clarified in an elegant way the nature of the electronic processes occurring in oxidation and reduction. The papers of Evans and his school on the so-called electron-transfer reactions are classics in that field. Possibly less well known but no less penetrating were his contributions to applied wave mechanics and the statistical mechanics of surfaces, and one of his most important contributions to the theory of bond dissociation energies was made only just before his death. The 1953 Jubilee Discussion of the Faraday Society on "Solutions of Non-electrolytes" was originally conceived by Evans.

Outstanding as a physical chemist, M. G. Evans was equally outstanding as a person. His industry and great ability were matched only by his extraordinary modesty and a personal charm which won him the affection, as well as the admiration, of all those who had the good fortune to meet him. He combined without affectation the hard-headedness of a scientific administrator and the subtlety and sensitivity of a creative artist. His nomination to the Government's Advisory Council on Scientific Policy and to the Scientific Advisory Council of the Ministry of Supply imposed on him a heavy burden of additional responsibility. Nevertheless, in spite of the severe strain to which he undoubtedly subjected himself, Evans was always ready to help those who came to see him with scientific or personal problems, and there will be many of his friends who will sadly miss his wise and sympathetic counsel.

H. C. LONGUET-HIGGINS

---

## Prof. V. N. Ipatieff

PROF. VLADIMIR NIKOLAEVICH IPATIEFF died in Chicago on November 29, 1952, just one week after his eighty-fifth birthday. Few men of science in our times have had more remarkable careers.

Born in Moscow in 1867, he attended a series of military schools and graduated from the Michaelovsky

Artillery School in 1892. He had developed an interest in chemistry several years before this and established a private laboratory from his small earnings; because of the nature of the curriculum and the instruction, most of his chemistry was self-taught. He remained at the Michaelovsky Artillery School as an instructor in chemistry and later became its first professor of chemistry. During 1896–97 he was sent to Western Europe, where he studied with von Baeyer in Munich and with Vielle and Sarraut in Paris, and in 1907 the chair of chemistry in the University of St. Petersburg was added to his duties.

During the First World War, Ipatieff was a lieutenant-general in charge of the Russian chemical industry, and because of his distinction he continued to hold high office during the Soviet regime. From 1921 until 1926 he was a member of the Supreme Economic Council of the Soviet Union, and in 1927 an institute for the study of high-pressure reactions was established for him. However, the scientific climate was increasingly distasteful to him and, in the company of his wife, he managed to leave Russia. After a short stay in Germany, he went to the United States in 1931 to become a lecturer in chemistry at the Northwestern University, Evanston, Ill., and director of research at the Universal Oil Products Co. In 1938, in order more easily to pursue purely academic research and to be able to teach his techniques to students, he established the Ipatieff High-Pressure Laboratory at the Northwestern University with the support of the Universal Oil Products Co., and he was actively engaged in his positions at the University and with the Company until two weeks before his death.

Commencing his career in the United States at an age when most men retire, Ipatieff published thereafter about a hundred and fifty scientific papers and obtained more than two hundred patents. He had already published some two hundred papers before he left Russia, starting with one in 1892, "Chemical Investigation of the Structure of Steel". The many honours that he received are too numerous to enumerate here, but mention should be made of the fact that he was the only man to have held regular membership in the national academies of science of both the U.S.S.R. and the United States (though his membership in the former, along with all other Russian honours, was cancelled by the Soviet Government in 1936 following his repeated refusal to return to the U.S.S.R. His wife, Barbara Demitrievna, with whom he had celebrated in 1952 their sixtieth wedding anniversary, survived him but a few days and died on December 9. Of their children, a son and a daughter still live in the U.S.S.R., one son was killed in the First World War and another lost his life while fighting tropical fevers in the Belgian Congo.

Ipatieff was a man of charm and kindness who enjoyed social contacts. He was always ready with encouragement and assistance to anyone interested in advancing science. He was an indefatigable worker who set himself a hard schedule, any disturbance to which upset him, and in particular his rare illnesses especially outraged his sense of order. While his life was primarily devoted to science, he had a number of other interests. He was a devout member of the Russian Orthodox Church, though no narrow sectarian, and he read widely in literature. In his earlier days he was an expert rider; fishing and swimming mainly occupied his vacations until a few years ago, and he was a great walker.

After some work of interest in ordnance and some in classical organic chemistry, of which that on the structure and synthesis of isoprene was particularly notable, Ipatieff became interested in heterogeneous catalysis, for he thought that high pressures of hydrogen would facilitate the hydrogenation of organic compounds. In testing this hypothesis he had to develop equipment for working at high pressures, in which task he was helped by his training as an artilleryman, and in 1903 he developed the first practical experimental autoclave for working at high pressures. He devoted much of his life to the exploitation of this discovery in a wide field of catalytic reactions, particularly hydrogenation. His pioneer work in high-pressure hydrogenation had revolutionary effects upon laboratory and technical procedures in many fields of chemistry. He was the first to recognize the use of promoters in heterogeneous catalysis. His work in the United States is notable for the discovery of the 'solid phosphoric acid' catalysis for the polymerization of olefines, for the discovery of the alkylation of olefines by *iso*paraffins and for work in the isomerization of alkanes. His research was one of the main sources of the revival of interest in hydrocarbon chemistry and of aliphatic chemistry in general and may be considered as the origin of much of modern petroleum technology.

Several months ago the Universal Oil Products Co. entered into negotiations with Northwestern University to establish the Vladimir Ipatieff research professorship, by which the Company will grant the University 25,000 dollars annually for the salaries of the professor and an assistant and for other expenses. It is a source of much gratification that Ipatieff had been informed of the final details of this professorship a few days before his death.

Robert L. Burwell, Jun.

## Dr. K. G. Blair

Kenneth Gloyne Blair, who at the time of his retirement was a deputy keeper of the Department of Entomology of the British Museum (Natural History), died at Freshwater, Isle of Wight, on December 11. Born at Nottingham on December 22, 1882, he was educated at Highgate School and Birkbeck College, London. After a brief period spent in other government offices, he transferred in 1910 to the Natural History Museum, being appointed assistant in the Department of Zoology, which then included entomology.

Under Dr. C. J. Gahan, Blair was put in charge of a large section of the Coleoptera comprising principally the Heteromera, which had perforce been largely neglected for many years. His systematic overhaul of these collections resulted in the publication of numerous papers concerned with the critical revision of genera and species, the description of new ones, the elucidation of the work of the early authors, a catalogue of the Pythidæ and Pyrochroidæ, and so on. Concurrently he published many papers of faunistic interest, based largely on collections made by various expeditions. These ranged from Mt. Everest, Krakatau, Samoa, Fiji, the Mentawi Islands, Christmas Island and the Marquesas in the East, through southern Arabia and South Africa to the Galapagos Islands.

But it would be wrong to base any estimation of Blair's contributions to entomology solely on the evidence of these works. He was at his best in the field among living insects, where he had a quite amazing flair for the 'good thing' and in consequence added considerably to our knowledge of the British fauna in nearly all orders of insects. Insect luminosity, and the complex inter-relationships of the inhabitants of plant galls, fascinated him and were the subject of several papers; fossil insects, myrmecophiles, insect stridulation and the morphology of beetle larvæ also attracted his attention. Up to the time of his retirement, due to ill health attributable to service with the Seaforth Highlanders during the First World War, he took a most active part in the proceedings of the societies to which he belonged. He was president of the South London Natural History Society in 1920, 1921 and 1931 and of the Royal Entomological Society during 1940–41. He is mourned by a very wide circle of friends, who will always remember gratefully the help he gave so freely and modestly to all who sought it, from his unusually wide store of knowledge and experience.

N. D. Riley

## Mr. E. G. Dymond

Edmund Gilbert Dymond died suddenly in Edinburgh on October 26. He was born at Hairwain, South Wales, in which town his father was engaged in business as a civil engineer. Between the ages of twelve and eighteen persistent ill-health made regular schooling impossible, but at the latter age he entered St. John's College, Cambridge, and thereafter lived an active and productive life. Only his early death reminded his friends that his energy and enthusiasm must often have outmatched his strength.

Dymond obtained first-class honours in physics in Part 2 of the Natural Sciences Tripos in 1922, and was awarded a Hutchinson research studentship by St. John's. In 1925 his College elected him to a fellowship. He had spent two of the intervening years in research at the Cavendish Laboratory, and the third as International Education Board Fellow at Göttingen. The following year he spent in Princeton. During the whole of this time, and throughout the next five years, when he was back in Cambridge, Dymond investigated various problems of electron collisions in gases.

In 1932 Dymond moved to Edinburgh, first as Carnegie Teaching Fellow, then as lecturer, and after 1948 as reader in natural philosophy. Soon afterwards his main research interest changed, and as a member of the Wordie expedition to North-West Greenland in 1937 he obtained records of cosmic ray intensity, using balloon-borne apparatus up to a height of about twelve miles. About the same time he released his first balloons from the Edinburgh district in similar investigations. This work remained interrupted throughout the Second World War, but Dymond continued his contribution to upper-atmosphere physics at Kew Observatory, where he developed and perfected the British *radio-sonde*. He returned to Edinburgh in 1946.

Building up equipment again after the War, and gathering a small research team around him, he was favourably placed to add considerably to our knowledge not only of cosmic radiation at great heights, but also of ozone distribution. However, only one major investigation was complete at the time of his death. The progress of the others will be slower for lack of his direction.

N. Feather

## Prof. L. Lapicque

Colleagues and friends in every country will regret the death, at the age of eighty-six, of Louis Lapicque, professor at the Sorbonne during 1919–36 and the leading figure in French physiology. His early researches were biochemical and they were followed by an expedition to the Andaman Islands to collect anthropological data; but in 1902, after his return to France, he took up the studies of excitability in nerve and muscle for which he became famous.

Lapicque used new methods to explore the relation between the duration and the strength of an effective electric stimulus: his curves showed the inadequacy of Nernst's treatment and led to new ideas based on the measurement of the 'chronaxie', a quantity giving the time factor of the excitation process. In collaboration with Mme. Lapicque he studied the chronaxie relations of a wide variety of tissues and demonstrated their essential similarity. The theory of isochronism which he afterwards developed may not have had all the far-reaching implications suggested by it, but his ingenious experiments and trenchant exposition have a classical quality which will be long remembered.

Between the two World Wars, Prof. Lapicque played a decisive part in the development of physiology in France. He was a welcome figure at international gatherings, where he spoke lucidly and with conviction on the problems of scientific co-operation. Vigorous in body as in mind, a keen yachtsman and a charming host, he was a worthy representative of the great traditions of his country.

E. D. Adrian

# NEWS and VIEWS

## Chair of Mining in the Imperial College, London: Prof. J. A. S. Ritson

Prof. J. A. S. Ritson vacated the University of London chair of mining at the Royal School of Mines, Imperial College, in October 1952, after a distinguished tenure of seventeen years. He is a graduate of the University of Durham, and started his professional career as inspector of mines in the Scottish, Yorkshire and South Wales coalfields. After distinguished service in the Army during the First World War he occupied the chair of mining in the University of Leeds during 1923–35, where he devoted much of his research to the improvement of mine rescue appliances and shot-firing techniques. Since his appointment to the Royal School of Mines, Prof. Ritson has maintained his keen interest in coal mining, and rapidly gained a high reputation as an expert on problems of metalliferous mining, based on experience won in various parts of the world. Among his multifarious duties he has acted for many years as Crown mineral agent, as a member of the Coal Commission, and as deputy chairman of the Mineral Resources Committee of the Ministry of Fuel and Power; during the Second World War he joined that Ministry for a few years as director of mining supplies and director of production. He served two sessions as president of the Institution of Mining Engineers and is now president-elect of the Institution of Mining and Metallurgy. Prof. Ritson has always been intensely interested in the education and training of mining engineers, and has played a leading part during recent years in organizing the expansion and intensification of courses in mining and mineral dressing at the Royal School of Mines.

### Prof. J. C. Mitcheson

PROF. J. C. MITCHESON, who has succeeded Prof. Ritson in the Royal School of Mines, comes of a family long distinguished for its outstanding services to the mining industry in the Midlands coalfields. After graduating at the University of Birmingham, he acted there for a year as lecturer in coal mining and demonstrator in mines rescue, before joining his father's consulting practice in Stoke-on-Trent in 1924. Afterwards he spent many years as agent and later as managing director of the Birch Coppice Collieries, near Tamworth, one of the largest collieries in the Warwickshire Coalfield. After serving as director of production for this coalfield, under the Ministry of Fuel and Power, he was appointed divisional chief planning engineer of the West Midlands Division, National Coal Board, returning in 1947 to practice as consulting mining engineer. During his twenty years experience in the management of collieries, he has been closely associated with research in mining and has pioneered many new methods of fuel efficiency, machine mining, coal preparation, underground lighting, accident prevention and roof control. Throughout this period he has served assiduously as a member or chairman of various education and training committees in the Warwickshire Coalfield. At the present time he is on the Mining Qualifications Board and the Safety in Mines Research Board set up by the Ministry of Fuel and Power, besides being intimately concerned with the new national certificate schemes for the mining industry. It is a happy augury that he should succeed to the chair of mining at the Royal School of Mines while serving as president of the Institution of Mining Engineers.

### Wilfred Hall Telescope

THE 15-in. visual refractor, with 15-in. photographic refractor attached, which formed the principal equipment of the late Dr. Wilfred Hall's private observatory near Newcastle, is now the subject of a bequest which it is proving regrettably difficult to accept. It was bequeathed in the first instance to the British Astronomical Association, and failing acceptance by the Association to the Royal Astronomical Society, provided that they "make use of it or cause it to be made use of on such terms and conditions as they may see fit, in some place chosen by them where in their opinion it can be of service to scientific research"; but it is estimated that to set it up will cost between two and three thousand pounds, even allowing for the fact that the will provides £500 towards the cost of removal—it cannot stay where it is.

It seems clear that only some permanent authority could properly be entrusted with such a long-term responsibility as this telescope must represent; if it is hard to find the money once, no scheme can be considered which would imply having to find it repeatedly, and a permanent loan to some educational body seems inevitable. The British Astronomical Association has been in touch with one body which hoped to pay half the cost, but after careful study it was decided that the number of members of the Association who would make any serious use of the telescope was too small, at any one site, to justify providing even half the cost from the Association's limited resources; it has therefore refused the bequest. It seems improbable that the Royal Astronomical Society could accept any financial liability either, and the telescope can thus be saved from the dealers' hands only if the entire cost of installation can be raised in some other way, before the Royal Astronomical Society in its turn refuses the offer. If the telescope is sold, the proceeds revert to Dr. Hall's estate. The will does not appear to demand that if accepted it shall be used purely for research, nor is it conspicuously a modern research tool. It could tackle certain tasks, and at the same time could introduce a number of people to some of the subjects and methods of research, and add greatly to a general knowledge of astronomy in its neighbourhood. It is to be hoped that some way may be found of grasping the opportunity that has arisen.

### World Power Conference: Annual Report for 1951

THE annual report for 1951 of the World Power Conference (pp. 32; from 201 Grand Buildings, London, W.C.2; 1952; 1s. 6d.) records a membership of forty countries, in thirty-seven of which National Committees have been formed; the German Federal Republic and Japan were admitted to membership at the July 1951 meeting of the international executive council. A brief chronicle of the sectional meeting held in New Delhi during January 10–16, 1951, is appended to the report; the technical sessions were held concurrently with sessions of the Fourth Congress of the International Commission on Large Dams and the First Congress of the International Commission on Irrigation and Drainage. The bound transactions of the former meeting have recently been published. An invitation to hold a sectional meeting in Rio de Janeiro during July–August 1954 was accepted by the international executive council, and an outline of the technical programme for this meeting is also appended: the topics to be discussed centre around the special energy problems of the tropical and sub-tropical countries. A report on the work of the World Power Conference in the field of water control and utilization was prepared for the secretariat of the Economic and Social Council of the United Nations. Statistical Year-book No. 6 of the World Power Conference is in the process of being published. A list of publications, issued or to be issued under the auspices of the international executive council, is also appended. At the annual general meeting of the British National Committee, Sir John Hacking was elected vice-chairman and Mr. F. G. Brewer honorary treasurer, in succession to Mr. H. Hobson and Colonel C. M. Croft, respectively.

### Pedo-botanical Surveys in the Belgian Congo

THE study of soils and the associated vegetation is now one of the principal tasks of the Institut National pour l'Étude Agronomique du Congo Belge (I.N.E.A.C.). A recent report ("Les Associations Végétales de la Plaine de la Ruzizi (Congo Belge) en Relation avec le Milieu". Publ. I.N.E.A.C., Sér. Sci. No. 52, pp. 1–321, 1952; 180 fr.), by R. Germain, deals with a pedo-botanical survey of the Ruzizi plain, the extensive and varied alluvial territory that lies between Lakes Kivu and Tanganyika. The physical environment, the flora, the several habitats —some nine, ranging from aquatic to forest paraclimax, are indicated—and their floristic associations are described in detail and illustrated by graphs and numerous excellent photographs. The plain is floristically rich, with 877 species of seed plants and pteridophytes, comprising 427 genera and 99 families. There is a marked dominance of species of the basic Sudanese–Zambesian flora (42·6 per cent) with 6 per cent of foreign species, chiefly from the west, the balance being transitional and widely distributed species.

## Electron Microscope and Microdissection

UNDER this title, R. Bovey (*J. Roy. Micro. Soc.*, Ser. III, **72**, 56; 1952) has described and illustrated a new technique for preparing biological specimens for study with the electron microscope. Using the de Fonbrune micromanipulator and an inverted microscope, the microdissection is made directly on a collodion film, or a film of 'Formvar', supported by a thin coverslip. The specimen is afterwards mounted on a grid. It is shown that the technique described can be successfully applied to the study of nuclear and cellular membranes and similar materials.

## Microbial Growth and its Inhibition

EIGHTEEN of the papers presented at the First International Symposium on Chemical Microbiology, which was held in Rome during June 1951, have been brought together under the title "Microbial Growth and its Inhibition" in No. 10 of the World Health Organization Monograph Series (pp. 285. Geneva: W.H.O.; London: H.M.S.O., 1952. 15*s*., 3 dollars or 12 Sw. francs); the papers had been previously published in the *Bulletin* of the World Health Organization. Many of the communications deal with the production, chemistry and testing of antibiotics, while problems of resistance are discussed by M. Welsch and L. L. Cavalli. The lag phase in the growth of *Pasteurella pestis* is investigated by S. S. Sokhey, and B. C. J. G. Knight discusses the physiological background to problems of growth inhibition. The role of the B group of vitamins in biosynthetic processes is dealt with by D. D. Woods, with particular reference to the metabolic functions of folic acid and $B_{12}$, and J. Monod presents his investigations concerning the specific inhibitors and inducers involved in the production of β-galactosidase in *Escherichia coli*. The collection of papers represents in general a number of contributions on specific aspects of microbial growth and of the properties of substances inhibiting such growth, rather than an outline or synthesis of present knowledge. Discussions are not published, but each paper concludes with useful summaries in both English and French.

## Centrifuges and *p*H Meters

A SURVEY of the requirements of biologists using centrifuges and *p*H meters has been made by the Institute of Biology. The analyses of the views expressed are given in two reports, which have been sent to all who collaborated in the survey and to all British manufacturers of the instruments. It is hoped that this presentation of the collected views of biologists, by making clear those features which are desirable but often lacking and the defects now experienced by users, will enable manufacturers to introduce the necessary modifications to existing models and to design future instruments to meet the expressed needs. Copies of the reports can be obtained from the General Secretary, Institute of Biology, Tavistock House South, Tavistock Square, W.C.1.

## A.S.T.M. Index of X-Ray Powder Diffraction Data

THE index, prepared by the American Society for Testing Materials, of X-ray powder diffraction data, widely known as the A.S.T.M. Index, has now been in use for about ten years, and it is recognized that it contains a number of wrong identifications which are likely to lead to confusion. The X-ray Analysis Group of the Institute of Physics therefore proposes to collect information on the errors which have been observed by users of the Index, and to publish as soon as possible in some suitable way a list of all those errors which seem to be substantiated. It is believed that many, if not all, of these errors have by now been noted by various workers and may in some cases have been mentioned casually in their publications; but in order to be of real use to others it is necessary that they should all be published collectively. Accordingly, everyone who has noted such errors is asked, whether he has already published them or not, to send the details to Dr. A. J. C. Wilson, University College, Cathays Park, Cardiff.

## Development of Mineral Resources in the United States

A PANEL of specialists in geology, mining and geophysics representing industry, government and the universities in the United States has been established to advise the National Science Foundation on policy questions connected with the recommendations of the President's Materials Policy Commission for development of the mineral resources of the nation. The first meeting of the panel was held in Washington, D.C., on November 29, 1952. In its report, the Commission recommended that "an intensive program of basic scientific research and technical development be undertaken on techniques and instruments of exploration for minerals", and the advisory panel of the Foundation will consider the need for an inventory of current research in exploration techniques and the formation of a committee to make such an inventory.

## Nineteenth International Physiological Congress, Montreal

THE Nineteenth International Physiological Congress will be held in Montreal during August 31–September 4, 1953, and one of the main concerns of the organizers of the Congress is to ensure that an adequate number of scientific workers from overseas countries will attend, despite the relatively heavy financial expenses that must necessarily be incurred by such participants. Physiologists, biochemists, pharmacologists and others from outside Canada and the United States who hope to attend the Congress are therefore asked to notify the secretaries of their national societies of that fact as soon as possible. This will aid the Congress organizers in arranging for special lectures and discussions to be held in the United States and Canada during the weeks preceding and following the Congress; it is hoped that those from overseas who are invited to take part in such functions will, in some cases at least, receive financial help that will appreciably reduce the cost of attending the Congress itself. Those who live in countries where there are no national scientific societies, and who hope to attend the Congress, should write directly to the executive secretary of the Congress at McGill University, Montreal. Arrangements are being made for an exhibition of scientific instruments and books at the Congress, and representatives of firms who wish to reserve space at this exhibition should write to the exhibit manager, Mr. Steven K. Herlitz, 280 Madison Avenue, New York, N.Y.

### Education in Chemistry: Discussion in London

A discussion on "Education in Chemistry", under the joint auspices of the London Sections of the British Association of Chemists and of the Royal Institute of Chemistry, will be held at 6.30 p.m. on February 18 at the Wellcome Research Institution, 183 Euston Road, London, N.W.1. The principal speakers will be Prof. C. K. Ingold, professor of chemistry, University College, London; Dr. J. W. Skellon, head of the Department of Chemistry, Acton Technical College; Dr. O. L. Brady, reader in organic chemistry, University College, London; Mr. R. W. Blount, chief inspector, Ministry of Education; and Dr. Norman Booth, research manager, British Oxygen Co., Ltd. Five themes to be covered will be: the aim of the revised regulations in science; external degrees in science; professional qualifications in chemistry; National Certificate in chemistry; and requirements of industry. Visitors are welcome to the meeting, and those who intend to participate in the general discussion should inform one of the secretaries, either F. C. Hymas, honorary secretary of the London Section, Royal Institute of Chemistry, 30 Russell Square, London, W.1, or T. Bewley, honorary secretary of the London Section, British Association of Chemists, Hinchley House, 14 Harley Street, London, W.1.

### Physical Society: Meeting in Leeds on Solid-state Physics

The spring provincial meeting of the Physical Society will be held in the Department of Physics, University of Leeds, during March 30–April 1. The subject of the meeting, "Aspects of Solid-state Physics", will be divided into three sessions as follows: analysis of magnetization curves; band theory of metals; and ferroelectricity and luminescence. Papers will be read by the following: A. F. Devonshire (University of Bristol); E. W. Elcock, J. Ewles, F. E. Hoare, K. Hunt, P. Rhodes, E. C. Stoner and R. S. Tebble (University of Leeds); H. Jones and E. P. Wohlfarth (Imperial College of Science and Technology, London); L. F. Bates (University of Nottingham); E. E. Schneider (King's College, Newcastle upon Tyne); W. Sucksmith (University of Sheffield). Non-members of the Society are welcome to attend the meeting, but must apply before March 9 to the offices of the Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7, where all further particulars can be obtained.

### Institute of Biology: London Meetings

The Institute of Biology is holding three meetings in London, which are experimental in nature, one purpose being to determine whether there is adequate support for the formation of a London branch of the Institute on a permanent basis. They are experimental also in their form and subject; for example, it is thought that some future meetings might be held jointly with other societies, and that the formation of study groups might be considered. The first meeting, an illustrated talk by Dr. N. Tinbergen, reader in animal behaviour, University of Oxford, on "The Functions and Causation of Animal Courtship", was held on January 22. The other two are as follows: a whole-day visit on February 21 to the Zoological Gardens, Regent's Park; and a meeting on "Setting about Research for Oneself", to be held at 7.30 p.m. on March 26, at the Society for Visiting Scientists, 5 Old Burlington Street, London, W.1, at which the principal speakers will be Dr. T. E. Wallis (sometime reader in pharmacognosy, University of London), Dr. W. B. Turrill (keeper, Herbarium, Kew), G. A. Steven (fisheries naturalist, Marine Laboratory, Plymouth) and Dr. P. Alexander (Chemistry Department, Imperial College of Science and Technology). The visit to the Zoo, for which a fee of 7*s*., inclusive of luncheon, will be charged, is restricted to members of the Institute only, and application should be made to D. Wragge Morley, 47 Downshire Hill, London, N.W.3. For the third meeting, members may bring guests. Further information can be obtained from the Institute of Biology, Tavistock House South, Tavistock Square, London, W.C.1.

### Announcements

King's College of Household and Social Science, University of London, has been granted by H.M. The Queen a royal charter of incorporation as Queen Elizabeth College.

Dr. T. E. Allibone, director of the Research Laboratory of the Associated Electrical Industries, Aldermaston, Berks, has also been appointed director of research to the Edison Swan Electric Co. and to the board of that Company.

Appointments to chairs in University College, Dublin (National University of Ireland), have been made as follows: Dr. T. E. Nevin (experimental physics); Mr. P. E. Mullaney (veterinary pathology and bacteriology); Mr. W. R. Kelly (veterinary medicine and meat inspection).

The following staff changes in the University of Leeds have been announced: K. L. Butcher has been appointed Brotherton lecturer in chemical engineering; Dr. J. P. Danby, lecturer in the Department of Leather Industries, and Dr. B. D. Wyke, lecturer in the Department of Physiology, have resigned their posts.

Australian National University scholarships for work in the University's Department of Nuclear Physics under Prof. E. W. Titterton have been awarded to the following graduates: Mr. A. J. F. Boyle (University of Melbourne), Mr. H. J. Hay (University of Otago, N.Z.), Mr. D. W. Smellie (University of British Columbia), and Mr. A. C. Riviere (University of Western Australia, now at the National Physical Laboratory, Teddington). The scholars will take up residence in Canberra at the commencement of the Australian academic year.

The American Society for the Study of Sterility is offering a prize of a thousand dollars for the most outstanding contribution to the subject of infertility and sterility. Entries for the prize must consist of an essay based on research in this field, and all essays must be received not later than March 1. Further details of the competition can be obtained from the Society, c/o Dr. Herbert H. Thomas, 920 South 19th Street, Birmingham, Alabama.

Erratum. In the title of the letter by Eileen L. Blackall and Prof. E. D. Hughes in *Nature*, 170, 972 (1952), for "*C*-Nitration" read "*O*-Nitration".

# RESEARCH IN BRITISH COLONIAL TERRITORIES*

ALL the main research schemes in progress under the Colonial Medical Research Committee were continued during 1951–52, and its seventh annual report records the filling of thirteen vacancies, although recruitment still lags behind requirements. A malaria-research scheme in Jamaica was concluded and established, with similar objectives, in the Gold Coast. A small grant was made towards a new project, an investigation of goitre in Nigeria. Two regional standing advisory committees for medical research have recently been instituted in East and in West Africa, respectively, to advise on the needs and priorities for medical research in these regions and to promote the co-ordination of current research activities within the region and with research workers in the United Kingdom. Under the East African Medical Survey, which is intended to be in three phases, work has been commenced on Ukara Island on Lake Victoria, an area chosen because of the poverty of the land and people, and of the possibility later of attempting eradication of malaria vectors. Here the collection of reliable vital statistics and information on the health and sickness of the population has been finished and has shown that the major problems are not medical. Bukoba, on Lake Victoria, was chosen for study because it is peopled by a wealthy tribe thought to be dying out because of a high incidence of venereal disease, and Kurimba, Tanganyika, because of the high incidence of schistosomiasis and of the possibility of integrating the findings with those of an intensive agricultural survey in progress.

The filariasis project in East Africa, although handicapped by shortage of staff, has shown that bancroftian filariasis here appears to cause no inconvenience to most infected individuals and produces no symptom-complex like the 'mumu' of the Pacific. The incidence of late complications like elephantiasis is related to the intensity of infection in any area, as distinct from the incidence. Studies on the chemotherapy of malaria in Malaya have indicated that widespread use of proguanil as a suppressive drug in a malarious area may result in the appearance of proguanil-resistant strains of *Plasmodium falciparum* and *P. vivax*. Tests with window-trap huts, supplementary to a house-spraying programme, confirmed that DDT at 200 mgm. per sq. ft. and BHC at 40 mgm. gamma isomer per sq. ft. are effective for nearly six months, but suggested that lower doses last only about two months against *Anopheles maculatus*. At Tambunan, North Borneo, encouraging results have been obtained from the experimental jungle clearance for the eradication of *A. balabacensis* and the malaria it carries. Work is being continued in West Africa to relate human age groups to the natural infections in *A. gambiae*, *melas* and *funestus*. Preliminary results of an experimental malaria eradication scheme at Ilara, Southern Nigeria, are summarized in the report, and in field-trials on selected African children, the 2 : 4-diaminopyrimidine derivative, 'Daraprim', was comparable with 'Mepacrine' in its schizonticidal effect on the trophozoites of *P. falciparum*, but the effective dose per child was as low as 5 mgm.

The West African Virus Research Institute, Lagos, has undertaken work on the use of the vaccine produced by the Pasteur Institute, Dakar, in outbreaks of yellow fever in the Gold Coast, and in Onitsha Province field-trials with aureomycin indicated no beneficial effect on the clinical course of yellow fever or on the level of viraemia. The East African Virus Research Institute, Entebbe, has been associated with the World Health Organization's scheme for delimiting the southernmost boundary of the yellow fever area in Africa and is examining human bloods from the Belgian Congo, Angola, Tanganyika, Northern Rhodesia and Nyasaland. Work by the Scrub-typhus Research Unit in Malaya has been consolidated, and investigations made in Malaya during 1951 by the Scrub-Typhus Research Unit of the United States Army Medical and Graduate Research School, with its headquarters at Kuala Lumpur, are summarized in the report. Specific antisera of great value in the accurate identification of blood meals and tsetse flies have been prepared by a 'cross-immunization' technique at the Lister Institute of Preventive Medicine, London, while the investigation of serum proteins continues at Makerere College, where a thorough investigation of the biochemistry of kwashiorkor as seen in children is in progress. Progress is reported in all established lines of research at the Tropical Physiology Laboratory, Oshodi, Nigeria, where a linear relation has been established between sweat-rate and corrected effective temperature and an extensive investigation has been made in the deep mine of the Ashanti Gold Fields Corporation at Obuasi, Gold Coast.

At the Field Research Station, Fajara, Gambia, investigations, assisted by a large contingent from the Medical Research Council's Human Nutrition Research Unit, into nutritional disorders and into infections, particularly with malarial parasites, which contribute to ill-health, have continued and work on food technology has been resumed. In Nigeria studies of the use of adrenocorticotropic hormone (ACTH) and cortisone in leprosy have been made.

During the year, grants totalling £373,553 towards new and existing schemes were made by the Committee for Colonial Agricultural, Animal Health and Forestry Research, the seventh annual report of which pays special tribute to the assistance given by the Commonwealth Institute of Entomology, the Institute of Biological Control, Ottawa, and the Mycological Institute. The East African Agriculture and Forestry Research Organization moved into its new headquarters at Muguga South, Kenya, early in the year. Its work on the relation between calcium and phosphate in the soil system is now being extended to the analyses of plant samples from fertilizer trials. Studies on groundnut virus diseases continued, substantial progress was made in studies of canker disease of cypresses in elucidating the resistance of different species to strains of the fungus and the relation between age of tree and susceptibility, and work has begun on the incidence of the bud disease of the pyrethrum plant caused by *Ramularia bellunensis*. The East African Veterinary Research Organization continued its work on animal trypanosomiasis, including the use of 'Antrycide', and on animal helminthology and nutrition, and the mobile unit concluded its tuberculosis survey in the Southern Highlands Province of Tanganyika. In West Africa, regional research schemes into rice cultivation and the rust disease of maize caused by *Puccina polysora* have been started, while at the West African Cacao Research Institute a satisfactory method was devised of controlling capsid bugs on young cacao. The former Oil Palm Research Station of Nigeria has been converted into a semi-autonomous West African Institute for Oil Palm Research, covering the needs of all the British West African territories.

---

* Continued from p. 114.

In cacao research in the West Indies, a study of the degree of pod-infection by witches' broom disease has indicated wide variations in the susceptibility of different clones to the disease. Research on the banana has shown that the most promising breeding programme is to raise primary tetraploids using the Gros Michel as the female parent, and that better male parents are required than those hitherto used in Trinidad and Jamaica. Arrangements have been made for research into leaf-scald disease of sugar-cane, a serious threat to the economy of British Guiana, and a small team of scientific workers is making an ecological land-use survey of British Honduras. Among work undertaken by Colonial Departments of Agriculture, Forestry and Veterinary Services mentioned in this report may be noted the investigations into the control of the root borer of sugar-cane, *Diaprepes abbreviatus*, in Barbados by the use of 'Agrocide' preparations and 'Aldrin', trials of insecticides in Fiji and the successful biological control there of *Cirphis unipuncta* in rice-fields, work on methods of rinderpest vaccine production in Kenya, on the sulphur content of 'gēlam' soils in coast alluvium in Malaya, on soil conservation in Sierra Leone, on coffee in Tanganyika and on the damage to coconuts caused by the coreid bug, *Theraptus* sp., in Zanzibar.

The fifth annual report of the Colonial Insecticides, Fungicides and Herbicides Committee gives fuller details of some work which is referred to elsewhere in these reports. The study of insecticidal surface coatings at the Colonial Insecticide Research Unit, Porton, has reached the development and field-trial stage. Treatment of various parts of ships voyaging through the tropics has given very promising results against cockroaches and ants, and appears to give some freedom from flies and mosquitoes entering at ports. In certain formulations the coatings are of value in protecting marine woodwork from barnacles and in the control of book insects in old libraries. Other work at Porton, at Rothamsted and at the Imperial College Field Station, Silwood Park, on the way in which contact poisons are picked up by insects, and the influence of particle-size and the type of surface on the amount picked up, should contribute to important improvements in insecticide formulations and methods of application.

Aircraft studies in East Africa in the application of chemicals to vegetation continued on a reduced scale: final observations on the treatment of 15 square miles of tsetse bush with DDT spray show a reduction of two species of tsetse by more than 99 per cent and of a third by more than 95 per cent. Two-year studies on the behaviour of *Anopheles gambiae* and *A. funestus* in huts treated with DDT, BHC and other insecticides do not support the view that DDT is ineffective against *A. gambiae* because it repels them from the huts, but 'Dieldrin' is more effective as residual spray against mosquitoes than either DDT or BHC. Trials of three new sprays for the residual spraying of houses for mosquito control are being carried out under Colonial conditions. Preliminary experiments have been conducted in Africa by the Unit of Experimental Agronomy, Oxford, on the use of defoliants and arboricides in control of tsetse fly.

In its fifth annual report, the Colonial Economic Research Committee reports extra difficulty in finding suitable candidates for undertaking research, and although several appointments were made to the regional institutes, recruitment of senior economists for short-term research appointments remains difficult. The Colonial Research Council has recommended the use of £100,000 of the remaining Colonial Development and Welfare Research allocation for promoting economic research, and part of this allocation will be devoted to research conducted by institutions in the Colonies. Considerable progress is reported in the Nigerian National Income Survey, which is being conducted by the Department of Applied Economics in the University of Cambridge, and Dr. P. T. Bauer's study of the structure and organization of trade in West Africa is almost complete.

The report of the Tsetse Fly and Trypanosomiasis Committee for the year ended March 31, 1952, states that the programme of work of the East African Tsetse and Trypanosomiasis Research and Reclamation Organization for 1951–56 provides for the continuance of the basic research of the past five years and for extensions into the field of animal trypanosomiasis when the facilities of the Central Trypanosomiasis Research Institute are available. Meanwhile, the prophylactic and curative properties of 'Antrycide' are being studied in co-operation with the East African Veterinary Research Organization. Full facilities at the West African Institute for Trypanosomiasis Research only became available during the year, but a tsetse breeding colony is being established in the laboratory. A new field-investigation on the epidemiology of human sleeping sickness was commenced in the Gambia, and a pilot experiment in Nigeria has shown that N'dama cattle show a remarkable tolerance to trypanosomiasis even when exposed to a severe challenge from *Glosina morsitans*. A zoologist has been appointed to collate information available on the mammalian fauna of Africa, and the Kenya Veterinary Department has further investigated delayed toxicity following the use of phenanthridinium compounds.

The annual report of the Colonial Fisheries Advisory Committee on Fisheries Research for 1951–52 reports a satisfactory recruiting position. There are now fifty-one fisheries officers, and at December 31, 1951, £1,532,500 had been allocated to thirty-four fishery research schemes, leaving a total balance in hand of £174,300, against which commitments for new schemes and the extension of existing schemes until March 31, 1951, amount to £120,000. At the Inter-Territorial Fisheries Research Station at Jinja on Lake Victoria, a comprehensive programme of research has been started with the object of acquiring an understanding of the principal factors which determine the density of fish populations in the various lakes of Central Africa. The importance of diatoms in the economy of the Lake has been demonstrated, and considerable light thrown on the rate of growth and sexual periodicity of fish living in tropical waters. Results obtained by the Inter-Territorial Marine Fisheries Research Station at

Zanzibar indicate that pelagic fishes haunt the edges of the shallow marginal waters. The large research trawler of the Western African Fisheries Research Institute has made her first six trips, and a hundred species of fish were identified; the Institute has also started a study of the ecology and biochemistry of mangrove swamp.

The report of the Director of the Anti-locust Research Centre on locust research and control for 1951–52 refers to the resumption of investigations on the conditions affecting the incidence of flight and the speed and direction of swarm displacements following the reappearance of desert locust swarms in East Africa at the end of 1950. The type of flight performed by locusts is of importance in determining the rate of displacement, and sustained flight appears to require high humidities. Research activities of the Desert Locust Survey included the exploration of less known desert locust areas in Arabia, and studies on locust biometrics, hopper behaviour and ecology. Intensive work has been carried out on the ecology and population dynamics of the Moroccan locust in Cyprus, and the Desert Locust Control Organization based on Nairobi was strengthened during the year. Growing international co-operation is an encouraging feature of the present control campaign. A memoir on the desert locust in the Indo-Pakistani-Persian area is being edited for the press, and completes the series of memoirs dealing with generalized seasonal breeding and migration of swarms throughout the desert locust invasion area.

## FISHERIES RESEARCH IN BRITISH COLONIES

IMMEDIATELY after the Second World War an extensive programme was set in motion under the Colonial Development and Welfare Act of 1945 to set up centres for fishery research in the British Colonies. It was realized that in fish there was a source of much-needed proteins which has scarcely been tapped. Of the research institutes to be developed the first to become established was that of the East African Fisheries Research Organization[*] at Jinja in Uganda under the directorship of Mr. R. S. A. Beauchamp. The publication of the Organization's annual report for 1951 affords evidence that the work of the Jinja laboratory is now beginning to bear fruit.

Research has been centred on Lake Victoria, and regular observations are showing how complicated are the conditions of a large tropical lake and how different they are from the classical picture supplied by the study of temperate lakes. The work is primarily aimed at finding out the economic possibilities of fishing, and to this end a study is being made of the fish populations, their food and ecology. With opportunities for regular observations over a number of years, it should be possible to answer outstanding questions on the growth and breeding of fish under tropical conditions. For this purpose a background knowledge of the conditions under which the fish live is essential, and investigations on the hydrology and algology are being made. Among results obtained to date, the possibilities of a new fishery for Mormyrids has been demonstrated; information has been gained about a number of fish which will help towards assessment of the effects of fishing on their populations[*]; the ability of fish to digest different types of algæ has been shown, as well as the notable importance of insect larvæ as food. Among other practical aims is the study of molluscs and the distribution of trematode parasites, especially *Schistosoma*.

But what is at once obvious from the report is the enormous and varied field for study, and the wealth of problems waiting to be solved in the teeming high-speed realm of tropical aquatic life. Many of these are fundamental questions which will need to be answered before the life-stories of the fish can be properly understood. In view of this it is most gratifying to note that visiting research workers from British and overseas universities are already finding their way to Jinja to work on their various private lines of research. In this way the work of the fisheries laboratory is advanced, and visitors and staff benefit enormously by mutual discussion and friendship. It is to be hoped that, when other laboratories are ready, more visiting research workers will seek the facilities they afford. The laboratory of the West African Research Organization at Freetown is reaching that stage.

## HUMBER LABORATORY FOR FISH RESEARCH

A NEW laboratory for fish research, to be known as the Humber Laboratory, was opened in Kingston-on-Hull on December 5 by Sir Ben Lockspeiser, with Dr. Franklin Kidd, director of food investigation of the Department of Scientific and Industrial Research, in the chair. Some hundred representatives of all sections of the fish industry were present, as well as representatives of various official bodies. The new venture was heartily welcomed on behalf of the industry by Admiral Sir Robert Burnett, chairman of the White Fish Authority, and by Mr. J. Croft Baker, chairman of the British Trawlers' Federation.

The new laboratory is a sub-station of the Torry Research Station, Aberdeen, which since its inception in 1929 by the Department of Scientific and Industrial Research has been the base for practically all the research undertaken in Britain into the problems of the preservation of fish as food. Aberdeen has proved a most suitable centre for research owing to the close proximity of fishing grounds for supplying experimental material and the presence of the University and other local research institutes, particularly the Marine Laboratory of the Scottish Home Department. However, during the past twenty-five years the area habitually fished by British trawlers has extended to the regions of Bear Island and Spitsbergen, the Barents Sea and Greenland, and on occasion Newfoundland and the Davis Strait. Nearly three-fifths of the white fish brought to Britain during 1951 came from these distant waters. This distant-water fishing is concentrated on the Humber ports of Hull and Grimsby, which together accounted for more than three-quarters of the distant-water catch and just over three-fifths of Britain's total white-fish landings of more than eight hundred thousand tons.

This was six times the quantity landed in Aberdeen, and was worth five times as much, namely, £22 million.

The distance of these prolific fisheries makes it more difficult to keep the catch in good condition on the voyage home, a journey that can take up to a week, after which inland distribution has still to be undertaken. In comparison, voyages to the nearer waters of the North Sea and Faroe Islands are much shorter and the catches much smaller. Since 1947 the Torry Research Station has been paying particular attention to the problems of improving the preservation of the distant-water catch, most of which consists of cod and haddock, and the establishment of the new Laboratory will provide a permanent base on the Humber which will make further work in this field much easier.

In opening the Laboratory, Sir Ben Lockspeiser pointed out that, of the three main sources of animal protein, meat and dairy produce have to be largely imported, much of it from dollar areas, while fish is mostly obtained by our own efforts. In consequence, it is rather surprising that although the British are consuming substantially less meat to-day than before the Second World War, they are, in fact, consuming per head less fish. Sir Ben gave as an example the kipper, a typically British product, of which, he said, the consumption is now only about half of what it was in 1947 and 1948. People will not eat fish willingly unless it reaches them in good condition, fresh or processed, and this raises questions of refrigeration, storage, smoking and canning. It would be wise to assume that Britain will have to rely increasingly on fish in the foreseeable future, and it becomes, therefore, more than ever important that the resources of fish, which are obtained with such cost in capital and labour and all too often in human life, should be husbanded. The Department of Scientific and Industrial Research, continued Sir Ben, is opening the new Laboratory on the Humber in the heart of the white-fish industry in order to help to come to grips with the practical problems of distant-water fishing. Industrial science is in the nature of a joint enterprise between industry and science. Although every now and then science takes a leap forward, creating a revolution in thought and practice, which it is vital for an industrial nation to recognize and take advantage of, more frequently advance is step by step, often in very small steps, every one of which has to be tested in practice. The Department of Scientific and Industrial Research attaches great importance to working in partnership with all sections of the industries it serves.

After the opening, visitors saw an exhibition of some of the results of recent work of Torry Research Station. The bacteriological problems of keeping fish fresh were illustrated, and an account was given of the methods used and results obtained in an extensive survey of the conditions of handling fish aboard distant-water trawlers, showing the temperature distribution in the fish holds and the loss of weight of fish during transport. Even with the most careful handling aboard ship, however, not all fish can be landed from the distant waters in a really fresh condition by the normal process of gutting, washing and icing. Another exhibit described work on the problems of preserving fish by freezing at sea, with samples of fish frozen in a new type of contact freezer now being developed for the purpose. The deleterious effects of the cold storage of fish at temperatures of − 10° to − 15° C. for a few months was demonstrated by contrast with the perfect condition of similar fish stowed at − 30° C. for up to twelve months.

Various physical, chemical and engineering problems involved in the preservation of fish by smoking and drying were illustrated. Some demonstrations were given of the recently developed humidity-sensitive element which utilizes some electrical properties of anodized aluminium (see p. 177 of this issue). Several by-products of the fishing industry, and new methods of recovery, were described as well as current research on fish proteins, and work on fish skin being carried out at the Zoology Department of the University College of Hull for the Department of Scientific and Industrial Research.

The buildings for the new Humber Laboratory have been erected by the Ministry of Works and comprise four laboratories, a workshop, offices, a library, and space for handling, freezing and smoking fish on a semi-commercial scale. Altogether, this new establishment will function as an integral part of the Torry Research Station, providing facilities for workers from that Station as well as for its own as yet small staff, and continuing work on various fronts—for example, certain aspects of fish chilling, freezing, smoking and drying. It is hoped that, in addition to *ad hoc* problems, the programme will include basic biochemical and physicochemical studies in fish preservation.

# PROBLEM OF FUTURE WORLD FOOD SUPPLY

THE Nutrition Panel of the Food Group of the Society of Chemical Industry has arranged a series of meetings devoted to the subject "Food and the Future". The opening meeting of the series, under the title of "The Problem of Future World Food Supply", was held on December 10, with Dr. J. I. M. Jones in the chair.

Mr. F. Le Gros Clark spoke on the "Yardstick of Population" and posed the question, "Will there soon be too many of us ?", pointing to an eventual finite limit to the population that could be supported by the world. Famines have always been local and temporary, never of world dimensions, but the real cause for alarm is that no one can foresee in what precise corner of the world hunger may occur. Optimists, he said, believe that men, even after a long period of suffering, will learn to control their fecundity, while pessimists foresee only disaster.

Mr. Le Gros Clark traced the growth in population over the centuries, suggesting an eventual total of 8,000–12,000 million before stability is reached. The problem of their food supply requires not mainly a technological transformation but a revolution in the habits of men and methods of farming—an agrarian revolution on a world-wide scale. The initiation of this revolution, he said, should have started fifty years ago, before the pressure of population had become so great. Nowadays, we cannot be excused because of ignorance, as perhaps could our grandfathers, who had less factual knowledge.

Most nations to-day, protested Mr. Le Gros Clark, are not giving the agricultural scientist and food chemist half the chance they should have of meeting the challenge. This is a matter for governments and people who move governments. The task before us, he concluded, is that of agrarian reform, carried out in such a way as to convert a largely illiterate peasantry into alert, modern farmers who can manage the breeding not merely of their farm animals but also of themselves.

Dr. E. W. Russell dealt with the "Factors Limiting Food Production". In Great Britain differences in output between farms depend upon soil, varying use of fertilizers and varying degrees of farming skill. Large areas of hill lands are producing only a fraction of the food per acre produced by the lowland areas, principally due to climate, lack of plant nutrients in the soil and relatively poor farming-skill in these areas. Skilled and energetic farmers must be attracted back to the hills, and this requires the provision of reasonable living amenities such as housing, transport and recreation in districts very deficient in these.

In the world as a whole, food production is limited by three groups of factors. First there are the inherent factors of the site: lack of soil, water, nutrients or a short growing-season. Then there are factors that harm the growing crop such as diseases and pests. Finally, there are human factors, including lack of skill, low activity due to disease, and social, religious and political brakes on production.

Dr. Russell gave examples of yields of rice in different countries, and showed that the extremely low yield in India, less than a quarter of that in Italy, had been doubled in one area by using better varieties, better water management and simple manuring. Crop production is limited by cold, but new strains ripening in a short season could be grown in cold districts before the frosts came. At the present time, the principal factors limiting wheat production in the Canadian prairies are believed to be lack of men and lack of markets rather than lack of suitable land. Dr. Russell also dealt with irrigation, fertilization of the soil and soil erosion.

A. E. Bender

## ROYAL OBSERVATORY, CAPE OF GOOD HOPE

### REPORT FOR 1951

The report of the Royal Observatory, Cape of Good Hope, chronicling the activities of the Observatory during 1951, has recently been published*. It is satisfactory to know that the modernization of the reversible transit circle, which had been originally built in 1900, was completed in 1951 and it was ready for use in November. An important change was the replacement of the twelve declination circle microscopes by twelve cameras, six on either pier, which, on pressing a button, photograph the position of the declination circle and automatically wind on ready for the next exposure. Various troubles with instruments have been eliminated; one of these arose from the harshness in the sun-and-planet differential through which the guiding motion is applied to the impersonal micrometer; and after trying alternative methods for securing a suitable differential motion, it was decided to retain, with a few minor changes, the form of drive introduced in 1911 by Mr. Hough. The Hipp chronograph, which frequently gave trouble, has been replaced by a new chronograph built at the Observatory and driven by a synchronous electric motor.

The Victoria telescope, now more than fifty years old, was used on 177 nights, 121 for the parallax and proper motion programme, 25 for photoelectric photometry, 19 for Fabry photometry and 12 for obtaining direct photographs in connexion with various photometric programmes. The instrument was also used for observing occultations both photoelectrically and visually. Arrangements have been made for an examination of the declination axis of the telescope, around which the motion has become increasingly stiff during the past few years. The astrographic refractor was used on 146 nights and the 7-in. telescope on 120 nights in connexion with the "Bright Star Programme"; as this is now finished, it is proposed to use the latter telescope only for visual observations, such as occultations and the micrometric measurement of double stars. The 6-in. telescope has been used to observe long-period variables and also for occultation work as well as for visitors. The tower telescope has been used for observing occultations and variable stars, and the photoheliograph is used daily to take two photographs of the sun. There have been developments in the photoelectric equipment during the year, two D.C. amplifiers and two power-packs having been designed and constructed, while great improvements have been made in the occultation apparatus which was described in the 1950 report.

In April 1951 an agreement was signed between the Radcliffe trustees and the Admiralty by which one-third of the time with the 74-in. Radcliffe reflector at Pretoria is made available to observers from the Cape. The scheme is to use the Radcliffe telescope for long routine programmes for which the organization of the Cape Observatory is particularly suitable and which are not likely to be undertaken by individual observers of the Radcliffe Observatory, and two routine programmes have been already started: one of these is for determining the radial velocities of the southern stars; the other is a photographic *Durchmusterung* of the southern Kapteyn Selected Areas. Among the miscellaneous items of the report are included observations of the spectra of a selected list of planetary nebulæ, photographs of extragalactic nebulæ, spectrograms of a number of specially interesting stars, and certain experimental work. The last includes some experiments made in collaboration with the Electronic Division of the National Physical Laboratory as to the capabilities of the new E.M.I. tube for astronomical photometry. Full-scale deflexions were obtained with the 74-in. telescope on stars of magnitude 15 without the use of an amplifier.

So many other matters are dealt with that it is impossible to mention them all, but one or two additional points are worth noticing. Mr. A. N. Cox, of the University of Indiana, visited the Cape Observatory in September 1950 and installed on the Victoria telescope the photoelectric photometer that had been previously used in the United States and at the Radcliffe Observatory. After his return to the Kirkwood Observatory, he compared the stars that he measured in the regions $C2$ and $C12$ directly with the North Polar Standards, and the remarkable thing is that the results were not in agreement with those found at Cambridge. It is suggested that the non-agreement may be merely one more indication of the grossly unsatisfactory nature of the present standard magnitudes in the northern hemisphere. Short descriptions are given of the time service, meteorological observations and publication of results. Continuous records were obtained on self-registering instruments of barometric pressure, temperature, humidity, wind direction and wind velocity; observations were made daily at 8 hr. S.A.S.T. The report ends with a list of the personnel and of distinguished visitors to the Observatory during 1951. Regular visiting days, which were started in August 1950, were continued during 1951.

# HÆMOGLOBIN AND BILIVERDIN IN PARASITIC CIRRIPEDE CRUSTACEA

By Prof. H. MUNRO FOX, F.R.S.
Bedford College, University of London

In 1946, Pérez and Bloch-Raphaël[1] announced the presence of hæmoglobin in the rhizocephalan cirripede *Septosaccus cuenoti* Duboscq, parasitic on a hermit crab at Roscoff. This increased from three to four the number of orders in the Crustacea Entomostraca known to possess hæmoglobin[2]; it is present in the Branchiopoda, Ostracoda, Copepoda and Cirripedia, being unknown only in the small fifth order, the Branchiura (containing *Argulus*). It is curious that, in Copepoda and Cirripedia, hæmoglobin occurs only in parasites. In contrast to the Entomostraca, no member of the Malacostraca possesses hæmoglobin in the blood or elsewhere in the body, while two malacostracan orders, the Decapoda and Stomatopoda, have hæmocyanin in their blood.

The roots of the cirripede *Peltogaster*, parasitic on hermit crabs, are green, unlike the yellow roots of *Sacculina*. Lederer[3] discovered that the green pigment of the roots of *Peltogaster paguri* (Rathke) is biliverdin; he based his conclusion on solubilities and the Gmelin reaction. Pérez and Bloch-Raphaël[1], using the Gmelin reaction, detected this pigment also in the roots of *Septosaccus*. It was natural that the latter authors should consider the biliverdin to be a degradation product of the parasite's hæmoglobin, as it is in the Vertebrata. Their paper was followed by two more on hæmoglobin and biliverdin in *Septosaccus*[3,4]. I have now had the opportunity, at the Zoological Stations of Naples and Villefranche, of studying these pigments in three other members of the Rhizocephala.

At Naples, *Peltogaster curvatus* Kossmann parasitizes two species of the hermit crab genus *Eupagurus*; it is found, namely, on *E. prideauxi* (Leach) and *E. excavatus* (Herbst)[5]. All individuals of *E. prideauxi* studied by me, but none of *E. excavatus*, bore the commensal anemone *Adamsia palliata* (Bohadsch). *Eupagurus prideauxi* is the commoner species of hermit crab, but only about 1 per cent of individuals are parasitized by *Peltogaster*, whereas about a quarter of the individuals of *E. excavatus* bear a parasite. The external part of the parasite is orange in colour, with a reddish tinge which is more or less pronounced in different individuals; the orange pigment is soluble in acetone and is probably a carotenoid. The parasite possesses hæmoglobin in solution in its blood, which is most conveniently obtained from the external part of the parasite near the stalk. Drops of blood of a standard depth, held between coverslip and glass plate of a compressorium, were examined with a microspectroscope. In the blood of some individuals the oxyhæmoglobin absorption bands were strong and in others weak. The accompanying table gives the numbers of individual parasites which showed oxyhæmoglobin bands of five arbitrary intensities.

| Host | Numbers of parasites with oxyhæmoglobin bands of various strengths | | | | |
|---|---|---|---|---|---|
| | Very weak | Weak | Medium | Strong | Very strong |
| *E. prideauxi* | 8 | 3 | 4 | 2 | 1 |
| *E. excavatus* | — | 1 | — | 9 | 10 |

The data show not only a considerable variation in the hæmoglobin content of individual parasites, but also a difference in amount of hæmoglobin depending upon the species of host. Normally a host carries a single parasite, but four individuals of *Eupagurus prideauxi* were found each of which bore two *Peltogaster curvatus* and usually the two parasites had quite different hæmoglobin contents. (Pérez and Bloch-Raphaël[1] found no hæmoglobin in *Peltogaster*, but they do not give species, host or number examined.)

The roots of *Peltogaster curvatus* within the host have an intense green colour, easily seen through the abdominal wall of the host. The green is due to biliverdin; I was able to show this, not only by the Gmelin colours, but also in three other ways. The roots were dried and then dissolved in methanol. (1) When nitric acid was added to the green methanol solution, the resulting purple had a strong absorption band with its axis at 493 mμ and a weaker one at 604 mμ. (2) When zinc acetate and iodine were added to the methanol solution an absorption band appeared at 636 mμ. Pure biliverdin treated in the same two ways gave the same bands. The wave-lengths were determined with the Hartridge reversion spectroscope. (3) Additional evidence of biliverdin was furnished by the solution in methanol with zinc acetate and iodine showing a pink fluorescence in ultra-violet light, which changed to a green fluorescence on the addition of more iodine.

In one individual of *Peltogaster curvatus*, nearly fully developed nauplii were present in the mantle cavity, most of them still within their embryonic membrane. They were light yellowish-pink in colour and contained no detectable hæmoglobin, although the parent had the pigment in its blood. Bloch-Raphaël[4] found biliverdin in the ripe eggs of *Septosaccus* and "bile pigments" in the nauplii. She remarks that these degradation products of hæmoglobin which are in the larva will be able "in the host" to take part in the synthesis of hæmoglobin. This statement is unjustified, since bile pigments are not known to be a step in hæmoglobin synthesis.

The second rhizocephalan species examined was *Parthenopea subterranea* Kossmann, parasitic on the anomuran *Callianassa laticauda* Otto. This is the only existing species in the genus *Parthenopea*, and it is known only from the Gulf of Naples, where 1–2 per cent of individuals of the host species are parasitized. The external parasite has a pinkish-orange colour, this pigment again being soluble in acetone. Eight parasites were examined spectroscopically but no oxyhæmoglobin bands were detectable, even in the pinkest specimens. The blood contains a variable quantity of a violet-pink pigment which has no absorption bands. With pyridine the blood gives only a weak α-absorption band of hæmochromogen: thus little hæm is present.

The part of *Parthenopea* internal to the host consists of ramifying green roots. Again the green colour is due to biliverdin, giving Gmelin's test. The colour is not so striking as in *Peltogaster*, but this is probably because the roots are more slender and are not bunched together. Here we have an animal with a bile pigment but no hæmoglobin. Biliverdin is already known from a crustacean lacking hæmoglobin, namely, an American 'crawfish'[7], in which it has been found in the liver. This fact, together with the presence of biliverdin without hæmoglobin in *Parthenopea*, suggests that in *Septosaccus* and *Peltogaster* the biliverdin is not necessarily derived from the hæmoglobin. As stated above, *Parthenopea* has a hæm compound, although no hæmoglobin, in its blood, and the biliverdin in the roots may perhaps be a breakdown product of this hæm. Another example of animals that have a bile pigment but no hæmoglobin is provided by insects with green integument or blood, the colour of which is due to a blue bile pigment together with a yellow carotenoid[8]; the insects possess, of course, a hæm compound in the form of cytochrome. The mollusc *Aplysia* has urobilin in the liver and also in the externally secreted pigment aplysiopurpurin[9] without having hæmoglobin in the blood, but there is abundant hæmoglobin in the buccal muscles.

It has been known for a long time that the liver of some decapod Crustacea contains a hæmochromogen[10]. With a reducing agent its α-absorption band becomes visible, and a more intense band can be obtained when pyridine is added, through the conversion of this hæmochromogen and of other hæm compounds to pyridine hæmochromogen. In *Callianassa laticauda* it was therefore not surprising to find a hæmochromogen present in the liver. An examination was made of forty-four individuals, half of them parasitized, and it was found that more pyridine hæmochromogen is obtainable from the liver tissue of unparasitized than of parasitized animals. This suggests at first that the hæm in the part of the parasite external to the host is derived from hæm in the host. But this tentative conclusion is not well founded, for the lobes of the parasitized host's liver are visibly atrophied. Their deficit in hæm may therefore well be due to the disturbance in the normal development and functioning of the liver, rather than to a draining away of its hæm into the parasite.

*Peltogaster* and *Septosaccus*, which are parasitic on hermit crabs, contain hæmoglobin, while *Parthenopea*, parasitizing an anomuran, and *Sacculina*, on crabs, lack the pigment. In the first two genera the external parasite is within the hermit-crab's shell, or enveloped by the anemone *Adamsia*, in a situation where the oxygen content of the water may not always be high, whereas in the other two genera the external parasite is freely bathed by the sea water. This suggested that the hæmoglobin of *Peltogaster* and *Septosaccus* might be synthesized in response to oxygen deficiency as in *Daphnia*[11]. But, for the following reason, this cannot be so. The anomuran *Galathea squamifera* Leach at Villefranche is parasitized by the rhizocephalan *Galatheascus squamifera* Pérez. I was able to examine four parasites, on separate hosts. They were pinkish-orange in colour, had hæmoglobin in the blood and possessed green roots. In two specimens the hæmoglobin was strong, in two it was weak; there is thus the same variation in quantity as in *Peltogaster curvatus*. In *Galatheascus* the external part of the parasite is freely bathed by sea water, and so the possession of hæmoglobin cannot be ascribed to lack of oxygen. Thus neither causal nor functional reasons are as yet known for the presence or absence of hæmoglobin in Rhizocephala. [Sept. 24.

# GENETIC INTERACTION BETWEEN INFLUENZA VIRUSES

By Sir MACFARLANE BURNET, F.R.S.,
K. B. FRASER and PATRICIA E. LIND

Walter and Eliza Hall Institute of Medical Research, Melbourne

It is now well established that when bacteria are doubly infected with appropriately chosen strains of bacterial virus, 'recombinant' virus types may be obtained among the progeny liberated on lysis[1,2]. No final interpretation of the phenomenon has yet proved acceptable, Luria's hypothesis[3] of independent gene multiplication followed by reaggregation of the genetic apparatus of the virus from the resulting gene pool having been withdrawn as inadequate by the author on the basis of Dulbecco's results[4].

Technical difficulties make it impossible to handle animal viruses on the scale, or with the quantitative precision, possible with bacterial viruses. The use of growth in the allantoic cavity of the chick embryo and hæmagglutination methods, however, provides some approach to such precision in work with well-adapted influenza virus strains. There are now many convenient ways by which influenza virus strains can be characterized, and it is not difficult to find, for example, two influenza *A* strains which can be differentiated from one another by six or more conveniently demonstrable differences. Evidence for genetic interaction between two such virus types has been sought for some years in this laboratory, and in 1949 results were obtained indicating that by double infection of the mouse brain with a neurotropic influenza virus, *NWS*, and a non-neurotropic virus of different serological type (*MEL*, *SW* or *Oc.I.*) strains could be obtained of the second serological type but carrying the neurotropism and some of the other characters of *NWS* (Burnet and Lind[5]). This phenomenon is readily reproducible, but the interpretation that it represents an example of genetic recombination has not yet found acceptance among other workers.

In the hope of obtaining a more readily analysed example of such interaction between two viruses, attention has now been turned to double infection in the chick embryo. For the first series of experiments, the two strains *NWS* and *MEL* which had been used for most of the work previously reported were chosen. In a sense, the neurotropism of *NWS* for mice finds expression in the chick embryo by its capacity after inoculation on to the chorioallantois to invade the embryo and produce hæmorrhagic lesions particularly in the brain and muscles. Virus *MEL* has no such action. If mixtures of the two viruses with *MEL* in 100- to 1,000-fold excess are placed on the chorioallantois, hæmorrhagic brain lesions develop after three to four days incubation. Most such lesions contain both *NWS* and what we have called *NM* virus. The latter, which is serologically *MEL* and capable of producing hæmorrhagic lesions in the embryo, may be present in excess, so that it can be isolated by simple titration in the allantoic cavity or it may require the use of an anti-*WS* serum to suppress an excess of *NWS* before this can be done. When isolated and re-isolated by limit titration in the allantoic cavity, the *NM* strains derived solely from chick embryo manipulations are identical in all respects with those formerly obtained in mouse brain experiments. It is of particular interest that a considerable proportion are capable of producing fatal encephalitis on intracerebral inoculation in mice. Of nine tested, four were consistently lethal, one strain produced a proportion only of deaths and four gave rise to no recognizable symptoms. This is very much the same distribution of pathogenicity which was found among the *NM* strains (defined on certain *in vitro* characters) obtained in mouse experiments[6].

On the hypothesis that *NM* virus was liberated from cells doubly infected with *NWS* and *MEL*, it was decided to use a method developed in this laboratory by Cairns[7] for obtaining 'first-cycle' virus from the allantoic cavity. Briefly, a large dose of a mixture of *MEL* and *NWS* virus, adjusted to approximately equal concentration of the two viruses on the basis of their hæmagglutinating titres, was inoculated into each of four to six 11-day embryos. After one hour's incubation, 2,000 units of semi-purified receptor-destroying enzyme of *Vibrio choleræ* was introduced into the cavity to liberate any adsorbed but non-infecting virus and to prevent loss by adsorption of the liberated first-cycle virus. The allantoic sacs were repeatedly washed out with warm saline and then left until half-hourly tests showed a rising hæmagglutinin titre. The fluids were then harvested and a pool of all satisfactory fluids tested for its content of virus. By appropriate titrations with and without antisera against the two viruses, one such pooled first-cycle fluid was found to contain *MEL* $10^{8 \cdot 3}$ and *NWS* $10^{8}$ infective units. An artificial mixture of the same composition was prepared and the two tested in parallel by titration on the chorio-allantois in the presence of anti-*NWS* serum. Three consistent experiments showed death of embryos with hæmorrhagic lesions from which *NM* virus was isolated, when the first-cycle fluid was used. The artificial mixture gave in two experiments only one out of twelve and one out of eleven embryos with lesions, in each case due to *NWS*. This was taken as evidence that the production of *NM* virus was possible in a single cycle of infection. It also seemed to eliminate any possibility that the *NM* strains arise by simple mutation from *MEL* or by some direct effect of the tissue environment.

The next step was to replace *NWS* by another *WS* variant, namely, *WSE*, which has no neurotropic activity in the mouse but is equally invasive and lethal for the chick embryo. It differs, too, in growing much more freely in the allantoic cavity than *NWS*, reaching the same level of hæmagglutinin as *MEL*. The choice of this pair of viruses was very fortunate, for in both the two extensive experiments so far completed the first-cycle fluid has been shown to contain in more or less equal amount four types of virus, namely, the two original forms *MEL* and *WSE* and two new types *M*+ and *WS*−, each of which combines some of the characters of both original forms. There are six well-defined characters which can be used to differentiate *MEL* and *WSE* viruses, and it is convenient to use these to designate *MEL* as *ABCDEF* and *WSE* as *abcdef*, each letter corresponding to one of the differentiating characters as follows:

*Aa*. Serological type *WS* or *MEL* as shown by hæmagglutinin inhibition tests with appropriate immune sera.

*Bb*. Heat stability: *MEL* hæmagglutinin resists 30 min. heating at 62°, whereas *WSE* hæmagglutinin is destroyed.

*Cc*. Conversion to 'indicator state' by simple heating at 56° for 30 min. When tested with ovomucin or meconium inhibitor, heated *WSE* hæmagglutinin is strongly inhibited; heated *MEL* virus is unaffected except by very high concentrations.

*Dd*. Reactivity of heated virus with sheep salivary gland inhibitor[8] *WSE* is strongly inhibited; no treatment of *MEL* has ever given a hæmagglutinin inhibited by this substance.

*Ee*. Production of hæmorrhagic lesions in the chick embryo after inoculation on the chorioallantois: this is characteristic of *WSE* but never shown by *MEL*.

*Ff*. Pathogenicity for mice by intranasal inoculation; with a dose equivalent to one agglutinating unit, *WSE* kills all mice usually four or five days after inoculation; *MEL* produces non-fatal lesions, grading 1–2 on the conventional scale.

The four types obtained then are represented:

| | | | |
|---|---|---|---|
| *ABCDEF* | *ABcDeF* | *abCdEf* | *abcdef* |
| *MEL* (22) | *M* + (6) | *WS* − (9) | *WSE* (4). |

The numbers in parentheses give the number of strains of each type isolated from thirty-seven virus-containing fluids obtained from embryos inoculated with dilutions of first-cycle fluid 85678 at or very near the limit of infectivity. From four fluids two types were isolated, accounting for the forty-one isolations shown. The only deviation from the four patterns shown above was that some *M*+ strains showed lower invasiveness for the embryo (*C*) than others, and in some tests two of the subinoculations from these have shown no lesions in the four embryos used, so they would be represented *ABcDEF*.

It will be seen that two characters only, *Cc* and *Ee*, appear to be transferable. It is particularly interesting that, in our experiments at least, one 'virulence' character, namely, the capacity to produce hæmorrhagic lesions in the chick embryo, is transferable, whereas another, pathogenicity for the mouse lung, is not. Similarly, one 'indicator' character, reactivity with ovomucin or meconium inhibitors, is transferable whereas behaviour toward sheep salivary mucoid is not.

These results at once exclude the possibility of simple mutation being responsible for the appearance of the new types. Some form of genetic interaction is clearly taking place, but there is no indication of a random reassortment of characters. Only four types have been observed, and the relationship between the new types *M*+ and *WS*− is a reciprocal one. It would be premature to speculate about the nature of the genetic interaction involved. The method used, however, may be one of general application and seems likely to provide an important approach to the interpretation of differences between virus strains.

# PHYSICAL PROPERTIES OF PAPER PULPS

## Elastic Properties of Wet Mats of Paper-making Fibres

In the manufacture of paper, the initial formation of the fibre web on the wire of the paper-machine takes place in the presence of a large excess of water, the removal of which constitutes an important problem in paper technology. Bulk removal, for example, by draining, suction and pressing, is employed before resorting to the more expensive method of drying by evaporation, but the physics of the former process has not been extensively studied. Most of the water is present as liquid water within the inter-fibre capillaries, and is sometimes, though incorrectly, called 'free water' to distinguish it from water molecularly adsorbed.

The hydrostatic tensions associated with different regains have been studied on textiles by Preston and co-workers[1]. In their technique, similar to a method used by Haines[2] and Schofield[3] for soils, bundles of immersion-wet fibres are placed on a fine sintered-glass plate, to the underside of which a hydrostatic tension is applied barometrically. This tension is transmitted by the continuous water channels to the water in the fibre bundle.

Using suspensions of papermaking fibres, small cylinders (1 cm. in diam. and 1·5 cm. high) were formed by drainage in a manner resembling the formation of the wet paper web on the machine wire. At moisture contents (gm. water per 100 gm. dry fibre) up to approximately 1,000 per cent, these cylinders will retain their structure for experimental purposes, although they are soft and easily deformed under small stresses. As well as changes in their moisture content, it has been found possible to measure changes in their dimensions with changes in tension. Figs. 1 and 2 show results of such measurements for a sample of an unbeaten commercial kraft pulp. The sensitivity of the apparatus allows volume changes to be measured to an accuracy exceeding 0·5 per cent and tensions to 0·01 cm. mercury. The smallest measurable tension is equivalent to a controlled relative humidity of 99·99999 per cent. In the present experiments, liquid tensions up to 20 cm. mercury have been used, covering a range in relative humidity from saturation to 99·98 per cent.

At low tensions, when no air is present in the matrix, it may be assumed that an approximately uniform hydrostatic stress acts throughout. The volume of water removed per c.c. of cylinder represents a volumetric strain, so that a bulk modulus may be calculated (Fig. 3). Since the water is completely free to move, the modulus, $k$ (1 bar = $10^6$ dynes/cm.$^2$), will be that of the fibre matrix only. This is the modulus which, on the paper machine, determines the resistance of the wet paper web to further loss of water during drainage and suction. Compared to a material such as wood ($k \approx 400$ bars) where the fibres are everywhere in contact, the modulus is very low. As the moisture content falls the bulk modulus rises, due doubtless to the tighter packing of the fibres. By applying small directional stresses to the cylinder, it is hoped to investigate other elastic and plastic properties of the fibre system.

At higher tensions the entry of air into the system (at the point *A*) renders uncertain the significance of the measured bulk modulus. This occurs when the tension is sufficient to empty the largest capillary present and is followed by a more rapid fall in the moisture content. Following entry of air, there is frequently a marked increase in slope in the tension-strain curve (Fig. 2). In some cases, due to elastic rebound of the fibres, there is even a slight increase in dimensions despite increasing applied tension. Thereafter, progressively smaller capillaries empty and the desorption isotherm (Fig. 1) gradually becomes much steeper. Large increases in tension here produce little drying effect. This region corresponds to the condition under which air is drawn continuously through the wet paper web at the suction boxes.

It will be seen (Fig. 1) that there is considerable hysteresis between the sorption and desorption curves. This has been observed invariably, even when no air enters the system. On sorption to very high moisture contents, where further swelling of the cylinder is opposed by its own weight, it has been found practicable to surround it with a non-miscible liquid of appropriate density. By thus counteracting the gravitational forces, repeated cycles of sorption and desorption may be followed to very small tensions, at which the volume may increase to several times its former value. It is hoped to make these matters the subject of further research.

## 'Freeness' of Paper Pulps and the Forces of Capillary Water Retention

In the manufacture of paper, the cellulosic raw material is first dispersed into separate fibres by chemical or mechanical methods and is then subjected to a mechanical process called beating, which alters the properties of the fibres and has a profound influence on the quality of the finished paper[1]. Standard methods which have been developed to give an objective measure of the degree of beating (for example, the Canadian freeness test[2]) all depend on the rate of drainage of water from the fibre suspension. A light beating gives a 'free' pulp, which drains quickly, whereas a heavy beating gives a 'wet' pulp, which drains slowly.

Experiments have been made in the past to see whether a wet pulp shows greater hygroscopicity than a free pulp in the usual (vapour pressure–moisture content) isotherm between zero and near saturation humidity. The results show either no difference[3] or only a small increase with beating[4]. This suggests that beating is influencing only water held by capillaries at humidities which are too close to saturation to be controlled by conventional methods. Experiments have also been made in this capillary-range by using the centrifuge, and these show a correlation with beating times[5,6], but true equilibrium was probably not attained. Also, in centrifuging, the increased gravitational field directly affects the packing of the fibres themselves, whereas, on the wire of the paper-machine, the water drains away under gravity and is drawn out at the table rolls and suction boxes, so that the mat itself is subjected only to the normal gravitational pull, except for the hydrostatic tension of the water in the capillary spaces.

The porous plate technique, described in the preceding communication, affords a simple and reliable method of maintaining relative humidities very close to saturation, since the liquid tension is thermodynamically linked with the vapour pressure of the capillary water[7]. The distribution of pore size depends on the initial packing of the fibres in the mat, and a method had therefore to be evolved which assured a controlled and reproducible formation. Using this technique, curves of moisture content against hydrostatic tension were obtained on an easy-bleaching sulphate pulp which had been beaten for various times in the Lampén mill[8]. The results are given in Fig. 1. The curves all show hysteresis between desorption and adsorption, but for the sake of clarity the adsorption curve is shown only for the unbeaten sample. For the same reason, the desorption curves for the intermediate beating times are not shown at low tensions. It will be seen that at the higher tensions the desorption curves are very similar in shape and are displaced parallel to the moisture-content axis according to the time of beating. Thus any arbitrary tension may be taken as standard (for example, 14 cm. mercury = 0·187 bar). In Fig. 2 the desorption moisture contents at this tension are plotted against the Canadian freeness figure. The general correlation is seen to be satisfactory.

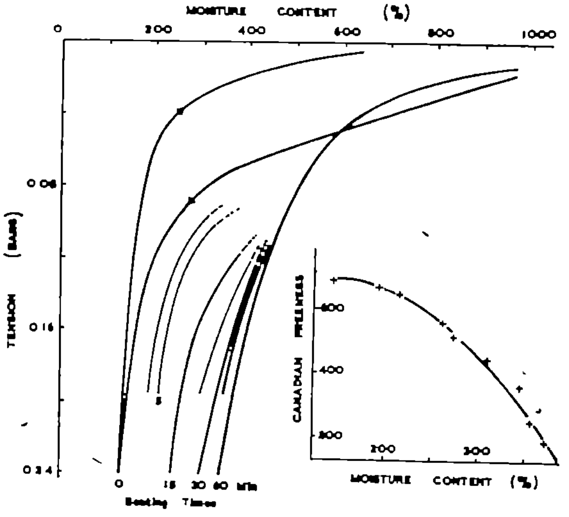

Fig. 1

Fig. 2

The porous plate technique is a static method, but the Canadian test is dynamic and therefore involves the rate of percolation of the water through the fibre mat rather than the tenacity with which the water is held. It may be argued on this basis that the porous plate method gives more direct information about the properties of the pulp from which the paper is eventually made. However, the rate of drainage is itself an important factor in paper-making since, on the machine, the water in the paper web may have no more than a few seconds in which to drain through the machine wire.

The main interest attached to these experiments is that they give, probably for the first time, a measure of wetness or freeness in exact thermodynamic terms, and that the data so obtained when used in conjunction with other experimental results described in the preceding communication may give precise information about the properties of the wet paper web under the conditions of manufacture.

## Effect of High-energy Radiation on Long-chain Polymers

A NUMBER of long-chain polymers, when subjected to high-energy radiation such as is provided in the B.E.P.O. pile at Harwell, are found to become cross-linked. Among the polymers which behave in this way may be mentioned polythene, polystyrene, 'Terylene', nylon and unvulcanized rubber. In other polymers, for example, methyl methacrylate, decomposition sets in after a very short irradiation period.

The degree of cross-linking produced in these polymers is proportional to the radiation dose over a wide range of values, so that it is possible to prepare specimens of any required degree of cross-linking without the introduction of foreign atoms or heat treatment. Apart from its commercial implications, this treatment offers considerable advantages in the study of long-chain polymeric structure, and in the investigation of rubber-like elasticity.

Principal attention has been given to the changes in properties of polythene when cross-linked. Above a certain short irradiation dose, corresponding to about two cross-links per molecule, polythene becomes insoluble in organic compounds, and no longer melts even at temperatures considerably above 120° C. After greater irradiation doses polythene becomes somewhat more elastic, and cold flow is largely suppressed at room temperatures, while above the usual melting temperature it acquires rubber-like elasticity. When subjected to considerable radiation, polythene becomes completely amorphous, hard and glass-like in character, even at room temperature.

Above 120° C., Young's modulus for cross-linked polythene is found to obey the theoretical law of rubber-like elasticity both so far as the variation with temperature and with degree of cross-linking is concerned. This enables one to obtain a relationship between the radiation dosage and resultant cross-linkage produced. Similar results are obtained when the amount of radiation needed to produce insolubility is determined.

During irradiation of polythene, gases are emitted, consisting mainly of hydrogen, with smaller amounts of methane, ethane, etc. In addition, surface oxidation takes place when the irradiation takes place in air. The weight changes $\Delta M$ depend on the radiation dosage $R$, and on the initial mass $M$ and surface area $A$ of the specimen:

$$\Delta M = -\alpha_1 MR + \alpha_2 MR^2 + \beta_1 AR + \beta_2 AR^2,$$

where $\alpha_1$, $\alpha_2$, $\beta_1$, $\beta_2$ are constants; $\alpha_2$ is very small. This formula is explained in terms of a volume evolution of hydrogen ($\alpha_1$), a surface oxidation ($\beta_1$), and evolution of paraffinic gases from near the surface only ($\beta_2$). As a result, values for the probability of breaking of C—H and C—C bonds have been derived[2].

The density of cross-linked polythene in the amorphous state (that is, above about 115° C.) has also been investigated. It is found that the variation of volume $V$ per gram with temperature $T$ and degree of cross-linking $c$ can be expressed in a form very reminiscent of the Van der Waals equation for a gas:

$$\left\{P + \frac{P_0}{1 - \beta c}\right\}(V - V_0) = RT/M,$$

where $\beta \sim 1$, $P_0$ is the internal pressure, and $V_0$ is a constant independent of $c$. The values of $V_0$ and $P_0$ are very close to those found by Spencer and Gilmore[1] in their studies of compressibility of ordinary polythene above the melting point.

Among other problems which may be mentioned is a study of the relationship between the degree of cross-linking and the swelling ratio for cross-linked polystyrene in benzene. This and other work will be reported in fuller detail elsewhere.

I wish to thank the Director, Atomic Energy Research Establishment, and Dr. H. M. Finniston, head of the Metallurgy Division, for permission to carry out this work and to publish the results.

## A New Focusing Principle applied to the Proton Linear Accelerator

A NEW design of synchrotron magnet has been announced recently by the bevatron group at Brookhaven[1]. It is stated that the novel focusing principle involved is applicable also to linear accelerators, but details are not given as to how the necessary apparatus is to be incorporated into an efficient radio-frequency accelerating structure. We wish to point out that there is only a minimum of interference with the radio-frequency system if the necessary fields are set up in the drift-tubes of a Berkeley-type accelerator[2]; and in particular that, if electric rather than magnetic fields are used, then a rather simple modification of the drift tubes is all that is required.

The fields considered strongly focus the particles in one direction transverse to the motion, but defocus them in the direction at right angles. Overall focusing can result if these two planes are interchanged periodically along the accelerator; this is the discovery of the Brookhaven group. Alternatively, the field structure could be made to spiral more or less continuously along the machine.

A method of applying electric fields is illustrated in Fig. 1. The drift-tube is divided by four longitudinal gaps and a potential difference applied between adjacent quadrants. If the gaps are small, the radio-frequency field will not penetrate to the centre of the tube, so that the shielding action of the latter

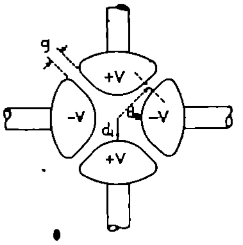

Fig. 1

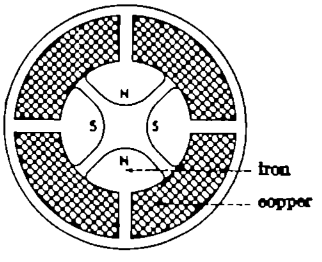

Fig. 2

is unimpaired. The inner surfaces are shaped as rectangular hyperbolæ to provide a better field distribution; at the drift-tube ends it might be desirable to change this shape, or to use guard rings, to avoid asymmetries in the radio-frequency radial forces.

My calculations indicate that with $d_1 = 1$ cm., $d_2 = 2$ cm., $g = 0{\cdot}5$ cm., and $V$ of order 6 kV., we should be able to focus protons of energy about 45 MeV. or more in an accelerator with synchronous phase 30°, operating frequency 200 Mc./s., and accelerating rate 2·3 MeV./metre. The field would be alternated every three or four drift-tubes. With the same accelerating rate and lower velocities, the radio-frequency defocusing forces are larger, and correspondingly greater potentials are needed. These can be avoided if the accelerating field is reduced in the initial part of the machine; or alternatively, grid focusing might be used in this section.

Protons of 45 MeV. travel with almost one-third the velocity of light ($\beta = 0{\cdot}3$). The electric field of 24 kV./cm. can then be replaced by a magnetic field of 270 gauss. This is to be established over the 0·5-cm. gap in Fig. 2. The current needed is 107 amp. per quadrant; with 10 sq. cm. of copper winding in each quadrant and a space factor of 0·75, the power dissipation is 1·2 watts per metre of drift-tube. With the same accelerating rate at lower velocity, the magnetic field required is larger; if only the current in the coils is changed, then the dissipation per unit length varies inversely as the fourth power of the velocity.

The divided drift-tube for electrostatic focusing is the outcome of an idea pursued by us for some time which involved the introduction of a charged conductor into the ordinary tube. I am indebted to my colleagues for much valuable discussion of all these methods. The Director of the Atomic Energy Establishment is thanked for permission to publish this communication.

## A 'Zero' Synthesis for Fourier Refinements

In the determination of crystal structure by means of X-ray diffraction data, the Fourier method[1] has long enjoyed the foremost place. Attempts have been made to substitute purely analytical techniques[2] depending upon either (*a*) the direct solution of the structure factor equations:

$$F_o(h,k,l) = \sum_r f_r \exp i\,\theta_r, \qquad (1)$$

where $f_r$ is atomic scattering factor of $r^{\text{th}}$ atom, $\theta_r$ is $2\pi(hx_r/a + ky_r/b + lz_r/c)$, $(x_r y_r z_r)$ are co-ordinates of the $r^{\text{th}}$ atom, and the summation extends over all atoms in the unit cell; or (*b*) by means of a process[3] which attempts to minimize the difference between some non-negative sum function of the difference between the observed structure factor amplitudes and those calculated on the basis of an assumed approximate structure, for example:

$$\sum_{h,k,l} (|F_o| - |F_c|)^2, \qquad (2)$$

$|F_o|$ and $|F_c|$ being respectively the observed and calculated structure amplitudes.

When the system of equations (1) is taken as the basis of solution, an immediate difficulty lies in the fact that only the modulus of $F_o$ is known *a priori*, so that the relatively simple equations (1) have to be replaced by a more complex set obtained by separation of real and imaginary parts and subsequent squaring. Despite these difficulties, formal analytical techniques have been devised[1] for handling the solution; these, however, depend (in general) upon obtaining large runs of observations having, say, fixed $k$ and $l$ values and consecutive $h$, which are not usually available.

It is clear that in principle the problem posed by the equations (1) should be solvable given any set of $F_o(h,k,l)$ values having at least $3n$ members, $n$ being the number of independent atoms in the unit cell. Actual sets of experimental data would be almost invariably grossly redundant when considered from this point of view, and it is interesting to consider if any method of solution exists in this case.

The general case, in which all phases are known, is, of course, trivial, since a straightforward Fourier synthesis

$$\rho(xyz) = \frac{1}{V} \sum_3 |F_o| \cos(\theta - \alpha) \qquad (3)$$

gives a density map the maxima of which occur at the roots of the set of equations (1). In two other cases, however, phase-angle data are available: (*a*) in those planes of which the phase is given by inequality theory; (*b*) in those planes of which the observed magnitude is zero. It is the second of these cases to which particular attention is to be directed in this communication, not only because of the ease with which such observations (or rather lack of them) can be obtained but also on account of the possible removal of ambiguity produced by the implied knowledge of phase.

At first sight, an application of the Fourier method to such a set of observations looks unpromising, since they are all zero; however, when the difference synthesis is considered, a more hopeful situation is apparent. It has been shown[4] that the synthesis:

$$(\rho_o - \rho_c) = \frac{1}{V} \sum_3 (|F_o| - |F_c|) \cos(\theta - \alpha_c) \qquad (4)$$

has the property that if the positions of the $(x_r y_r z_r)$ used to calculate $\alpha_c$, $|F_c|$ are marked upon it, the directions of steepest ascent at these points give the directions in which the $(x_r y_r z_r)$ must be moved in order to bring the trial structure into better agreement with the true one, and that magnitudes of shift can be estimated by a slightly more detailed analysis.

The reasoning of the original paper (*loc. cit.*) is still valid when $|F_o|$ is zero, and when only those terms for zero $|F_o|$ are included in the summation; thus the simplified expression:

$$\rho_c = \frac{1}{V} \sum_3{}' |F_c| \cos(\theta - \alpha_c), \qquad (5)$$

where $'$ indicates that only those planes for which $|F_o|$ are zero are included in the $\sum_3$, will give the directions in which the atoms of a trial structure must be moved in order to produce the most rapid convergence to a true structure.

It is not to be expected that such a refinement technique will lead to very precise co-ordinates, since to say that $|F_0|$ is zero can, in fact, mean only that it is less than some arbitrary lower limit of size. However, in view of the great ease of obtaining the observational material, it is suggested that the above technique may prove a useful addition to the existing armament of structure analysis.

## Internal Stresses caused by Disorder in Vitreous Materials

It is now generally recognized that one of the main characteristics of a vitreous material is that its atomic structure has no long-range order[1]. This means that the individual interatomic bonds will not have the length and direction which they have in a crystal, and, because of this, these bonds will not have their normal strength. If it is assumed that the bonds within a certain small region are subjected to a similar distortion, then it will be correct to think of this region as being subjected to a mechanical stress. It is of some interest to calculate the order of magnitude of these internal stresses.

It is clear that the resultant of all the internal stresses in the material must be zero. One of the simplest cases of a distorted structure in which the internal stresses are balanced is the edge dislocation. The equations governing the stresses in such a dislocation have been derived by Nabarro[2]. It can be shown from his equations that the stresses near the centre of the dislocation are of the order of $2G/\pi$, where $G$ is the shear modulus of the material. (It should be realized that this value is obtained from equations based on the assumption that Hooke's law applies for strains of the order of those present in a dislocation; this is, of course, not strictly true.) It is reasonable to assume that regions exist in a typical glass where the distortion is of a type similar to that existing in an edge dislocation, that is, it is a shear distortion; and that the stresses resulting from this distortion will be of the same order as those in a simple edge dislocation.

One consequence of this assumption will now be examined. Griffith[3] has shown that the theoretical strength of glass is of the order of 1,000 kgm. per sq. mm. Now it has just been suggested that internal stresses may exist in glass which cannot be removed by annealing, and which may be of the order of $2G/\pi$. Taking a typical value of $G$ for glass of $0{\cdot}25 \times 10^4$ kgm./sq. mm., the value for the internal stresses is calculated to be about 1,600 kgm./sq. mm. Of course, the internal stresses cannot be greater than the theoretical strength of the material. The values just given for the theoretical strength of glass and for the stresses due to disorder merely indicate the order of magnitude of these stresses; but the values obtained do suggest that, because of the large internal stresses of the material, it may be necessary to apply only a relatively small external stress to cause fracture of the material. It is therefore suggested that the relatively low breaking strength of glass may be partly due to its disordered structure; but it is realized, of course, that in massive glass articles (bottles, sheet glass, and so forth) at least, the flaws in the material which are always present as a result of the manufacturing process and the handling of the article in service may also have a marked effect on the strength.

The expression for the maximum stress of the centre of a dislocation suggests that there may be some relationship between the tensile strength and the shear modulus of glass. This is confirmed, to some extent, by experiment. Thus Murgatroyd[4] has found that, for fibres of a soda lime silica glass between 10 and 100 microns in diameter, the tensile strength increases with decreasing diameter and, at the same time, the shear modulus decreases. This is in agreement with the views just put forward; a decrease in the shear modulus will cause a decrease in the stresses due to disorder, so that a larger external stress will have to be applied for the internal stresses to reach the theoretical strength of the glass. If it is assumed that the greatest internal stress is given by the expression $2G/\pi$, then it is found that the sum of the greatest internal stress and the applied breaking stress is almost constant. This is shown by the results given in the accompanying table.

| Fibre dia. ($\mu$) | $G$ ($10^5$ kgm./sq. cm.) | Max. internal stress $= 2G/\pi$ ($10^5$ kgm./sq. cm.) | Applied breaking stress ($10^5$ kgm./sq. cm.) | Max. internal stress + applied breaking stress ($10^5$ kgm./sq. cm.) |
|---|---|---|---|---|
| 40 | 2·49 | 1·585 | 0·170 | 1·755 |
| 80 | 2·63 | 1·675 | 0·100 | 1·775 |
| 110 | 2·68 | 1·705 | 0·070 | 1·775 |

Other measurements which have been carried out on finer fibres of fused silica are not consistent among themselves. Thus Reinkober[5] has found that, for silica fibres of diameter less than 20 microns, there is a rapid increase in the shear modulus with decreasing fibre diameter, whereas Eberhardt, Kern and Klumb[6] have found that for silica fibres of the same diameter there is a slight decrease in shear modulus with decrease in diameter.

I am indebted to Mr. J. E. Stanworth, of this laboratory, for a number of useful discussions during the preparation of this communication; I am also indebted to Mr. L. J. Davies, director of research, British Thomson-Houston Co., Ltd., for permission to publish the work.

## Closed Pores in Synthetic Graphite

It is well known that the bulk density of a synthetic graphite is much lower than the density of the crystallites obtained from X-ray measurement: 25–30 per cent of the volume must be empty pore space. By measurement of the real density with three different fluids, we have shown that about 20 per cent of the total pore space cannot be reached by a liquid or gas unless the graphite is reduced to a very fine particle-size, or part of the structure is removed by oxidation.

The synthetic graphites studied were pure grades (99·9 per cent carbon), prepared in a commercial graphitizing furnace, having a bulk density of 1·6 gm./cm.$^3$. The displacing fluids used for density measurements were methanol, *n*-hexane and helium. The liquid densities were measured after prolonged refluxing in the liquid used. The standard density-bottle method was used for specimens 6 mm. or less in diameter, and larger specimens were weighed in air and in liquid. The densities of helium were measured after outgassing at 300° C. to a pressure of $10^{-4}$ mm. of mercury or less; no measurements were taken until two hours after admitting helium, and measurable drifts with time were seldom recorded after that period. The results are considered accurate to ± 0·3 per cent.

In all cases where they were directly compared, the liquid and helium densities agreed closely. For example, the density of a cylinder (15 mm. diameter) of synthetic graphite was measured as 2·091 gm./cm.$^3$ in *n*-hexane and as 2·093 gm./cm.$^3$ in helium after pumping off the hexane; the density of an oxidized dust was 2·224 and 2·220 gm./cm.$^3$ in methanol and helium respectively. There was no evidence of a molecular sieve effect, as has been reported for some cokes[1], that is, the measured density was independent of the molecular size of the displacing fluid.

The density of pure flakes of natural Ceylon graphite (99·5 per cent carbon) was measured as 2·253 gm./cm.$^3$ in methanol and 2·251 gm./cm.$^3$ in helium; these values amount to 99·3 per cent of the value derived from X-ray crystallographic data, which is[2,3] 2·266 gm./cm.$^3$. In contrast to this, the densities of specimens of the synthetic graphite were always lower than 2·21 gm./cm.$^3$. The densities of bulk specimens, that is, cylinders and plates, varied from 2·06 to 2·13 gm./cm.$^3$ with no systematic variation with specimen size or with the original position of the specimen in the large manufactured block. The densities of dusts (particle diameter less than 0·4 mm.) milled from the same blocks as provided the bulk specimens were uniformly higher, ranging from 2·15 to 2·21 gm./cm.$^3$, and these densities showed a tendency to increase as the particle-size of the dust decreased. For one dust examined, the sieve fraction − 36 + 72 B.S.S. had a density of 2·154 gm./cm.$^3$, whereas the density of the fraction passing a 240 B.S. sieve was 2·191 gm./cm.$^3$.

Thus all measured density values found for artificial graphite were 2–8·5 per cent lower than the experimentally determined value for natural graphite. The calculated X-ray density of a synthetic graphite comparable to that used by us (sample *A* 1, ref. 3) was only 0·2 per cent lower than the X-ray density of Ceylon graphite. The low observed densities therefore suggest the presence of inaccessible pore space in the micro-structure of synthetic graphite, formed either by the disordered stacking of the graphite crystallites or by intercrystalline linkages of non-graphitic carbon. Some of the blockages in the pores must be fairly far apart, since reducing the particle size to 70 microns opens up an appreciable fraction of the closed space.

The densities of some bulk and dust samples were re-measured after oxidation at 430°–500° C. in an air stream. The density always increased on oxidation, the increase being normally greater the larger the loss of weight. The density increase was most marked in the initial stages of the oxidation—the density of a 14-mm. diameter cylinder increased from 2·130 to 2·194 gm./cm.$^3$ on oxidation to 0·55 per cent loss of weight, and to 2·226 gm./cm.$^3$ on oxidation to 2·7 per cent loss of weight. It is suggested that slight oxidation may remove the pore blockages, either by first removing poorly crystallized material, or by oxidation occurring first at the edges and corners of crystals, and closed spaces may thus become accessible to the measuring fluid.

The significance of these results will be more fully discussed in conjunction with parallel adsorption measurements to be reported elsewhere. We wish to acknowledge experimental assistance afforded by Mr. E. A. Harper and Mr. H. Small, of this Establishment.

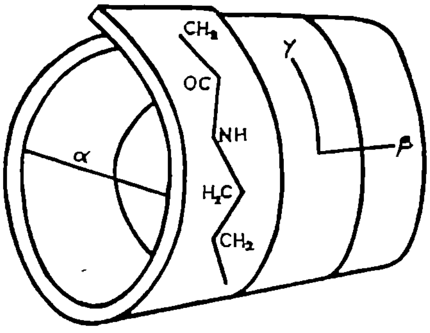
## Morphology of Crystalline Synthetic Polymers

In a previous communication[1], it has been reported that when polyethylene terephthalate crystallizes, it forms spherulites, which consist of radiating helically wound ribbons, and that other synthetic polymers behave similarly. The present communication describes effects observed with polyethylene and polyamides.

In order to observe the phenomena to be described, polyethylene and polyamide (nylon) melts were crystallized in thin layers between cover-glasses at a constant temperature within 20° C. of the softening point. Between crossed Nicols, spherulites were seen which, in addition to the usual black cross, showed a system of concentric extinction rings, and in some cases also the beginning of a zig-zag distortion of the crosses[1]. With decreasing temperature of crystallization, the extinction rings become gradually narrower and more closely spaced, until they can no longer be resolved with the optical microscope. The sign of birefringence of the polyethylene spherulites was negative, and that of the polyamides nearly always positive; by this it is meant that, regarding the spherulite as uniaxial, in the first case the major refractive index lies tangentially and in the second radially with respect to the spherulite. In very rare instances isolated negative polyamide spherulites have been seen, but the conditions for producing these are not known. All these effects can be explained by the morphology proposed in ref. 1. Accordingly, the above observations correspond to cases in which the radiating needles are closely coiled helices (helical angle only a few degrees), and the increasing separation of the rings with increasing temperature of crystallization would be due to the increasing diameter of the needles.

Thinner layers of melt crystallize to a felted mass of interpenetrating needles, which aggregate into airscrew-like structures with voids between. Still thinner layers produced isolated needles which direct observation showed to be helically coiled ribbons, as postulated from the extinction pattern.

Some conclusions could be reached about the orientation of the molecules within the ribbons themselves. It will be assumed that the chains are parallel to the length of the ribbons, as this is consistent with our ideas about aggregation of fibre-forming molecules. Owing to the close coiling, γ, the largest refractive index (coincident with the chain direction), will be perpendicular to the helical axis. In polyethylene, α and β, minor and intermediate refractive indices respectively, are nearly equal[2], whence the birefringence of the spherulites will be negative as observed. In polyamides the conditions are complicated by the fact that β is more nearly equal to γ than to α, as a result of the strong polarizability of the CO- and NH-bonds[3]. We assume that the hydrogen bonds lie in the plane of the ribbon, as this is most likely in view of the crystal structure[3]. Then if the ribbon is closely coiled so that its plane is parallel to the axis of the helix, the position of the refractive indices will be as shown in the diagram. When the same beam of light goes through a number of helices, γ and α will be averaged, the resultant being smaller[3] than β, which lies along the axis of the helix, and hence along the radius of the spherulite. Consequently, the birefringence will be positive as observed.



Schematic illustration of the arrangement of the molecules and the refractive indices of a polyamide within a helix

An X-ray photograph has been taken of a circular area 30 μ in diameter near the periphery of a spherulite of polyhexamethylene sebacamide, using the microbeam method of Herbst[4]. The diameter of the spherulite was 200 μ and the thickness 20 μ. The photograph showed that the planes containing the hydrogen bonds were parallel to the radius, and that the molecules were arranged tangentially. This picture is the same as that deduced from birefringence evidence. These X-ray findings differ from those of Herbst, who concluded that the hydrogen-bonded planes were perpendicular to the radius. Such an arrangement would give a negative sign of birefringence; but Herbst's note does not contain any statement about the birefringence.

The picture of the radiating helices has now been proved in several ways, and the frequent special case when the helices are closely coiled gives a satisfactory morphological explanation of the hitherto unexplained tangential molecular orientation often described in the literature of polymer spherulites.

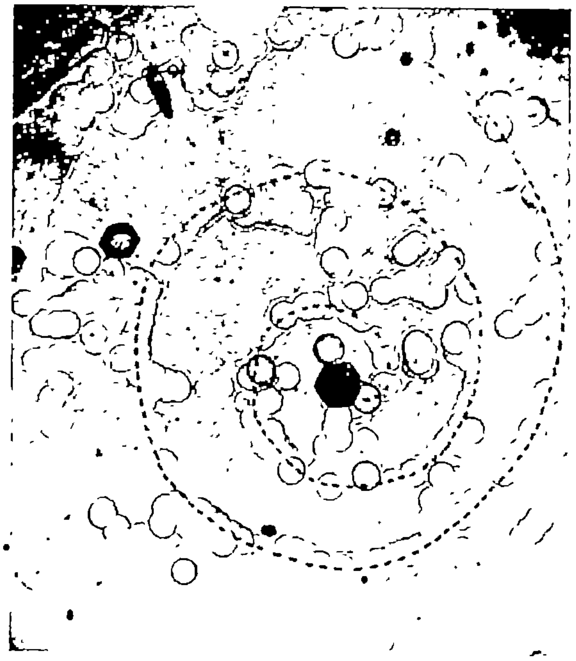
## Etch-pits and Dislocations

Prof. S. Tolansky and M. Omar have reported[1] the appearance of spirals on octahedral faces of diamond, after etching. The hypothesis was put forward that etch-pits had been formed along a spiral-shaped growth-front; but no proof was given.

In the course of a detailed interferometric study of etch-pits, a report on which will be published elsewhere[2], we made very similar observations on c-faces of silicon carbide. Crystals on which growth-spirals were present were etched in fused borax and silvered before examination. It was found that etch-pits had been formed all along the spiral growth-fronts, proving the correctness of Tolansky's point of view.

The accompanying photograph shows the crystal face after etching; the original spiral (step-height of the order of 600 A.) has been marked by a broken line. At the end of the dislocation line a very deep etch-pit (several wave-lengths) was formed, proving that the presence of dislocations makes etching easier. This last point is also strikingly shown on prism faces (110) of very perfect topaz crystals, where etch-pits form preferentially at the top of growth pyramids.



These observations suggest that etching at dislocations will take place following a mechanism which is formally analogous to the Frank mechanism for growth[3]. A striking feature is the difference between the deep polygonized etch-pits generated at the emergence of screw dislocations and the shallow rounded etch-pits formed elsewhere on apparently perfect areas of the crystal face.

This work is part of a research scheme supported by I.R.S.I.A. I wish to thank Prof. W. Dekeyser and Dr. S. Amelinckx for advice.

# Exudation of Material from Slip Bands at the Surface of Fatigued Crystals of an Aluminium–Copper Alloy

No satisfactory explanation of the fatigue mechanism of metals has yet been advanced. The generally accepted idea involving work-hardening and subsequent 'brittle' fracture cannot be substantiated by observation as being the only cause of fatigue failure. Observations I have made on pure aluminium and aluminium–½ per cent silver specimens have shown that the mechanisms of failure at high and low stresses are fundamentally different[1].

A type of crystal breakdown which it is believed has not been observed before, and which may contribute to the understanding of the initiation of fatigue cracks, has recently been observed during the fatiguing of an aluminium–4 per cent copper alloy in the solution heat-treated condition. During the early stages of the fatigue life of this material, some of the grains become covered with fine slip bands, as is usual with most of the materials examined. The new observation is that, as the cyclic stressing continues, certain slip bands become more heavily defined, and thin ribbons of material are exuded from these bands. These ribbons usually curl over at the leading edge as shown in Figs. 1 and 2. It is only possible to estimate an upper limit for the thickness of the exuded ribbon because of these curled edges. The diameter of the curled portion is usually about 1 micron; thus the ribbon thickness may be considerably less than the limit of resolution of the microscope. These ribbons may be continuous along the length of the slip band, but they usually break into shorter lengths. The wrinkled appearance of these short lengths suggests that the 'extrusion-rate' is varying along the band. These ribbons often

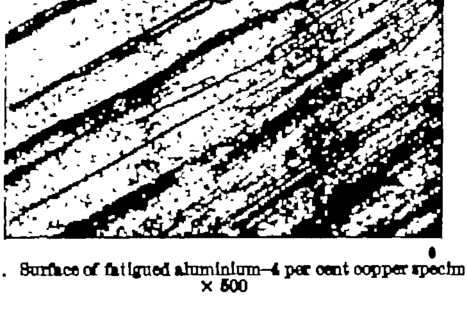

Fig. 1. Surface of fatigued aluminium–4 per cent copper specimen. × 500

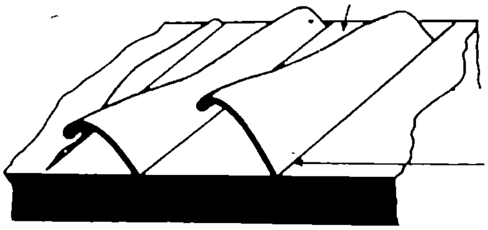

Fig. 3. Schematic diagram showing crystal debris at surface of crystal

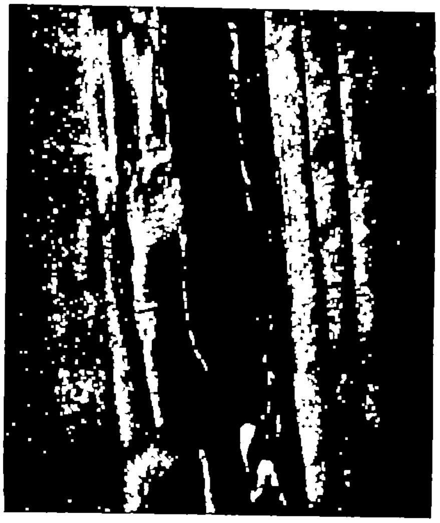

Fig. 2. Ribbon of exuded material showing 'extrusion' markings. × 1,500

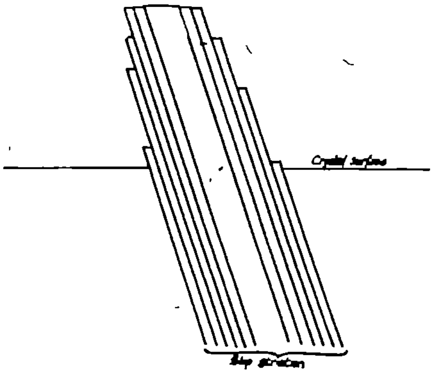

Fig. 4. Schematic diagram of a slip striation in which a layer of material may be exuded from the crystal surface

showed 'extrusion' markings as indicated in Fig. 3, and often other markings at right-angles to these are also observed.

The effect of the loss of this coherent material from the crystal surface must be to leave crevasses which will form very effective stress raisers. The mechanism by which this material is exuded from the surface is not clear, but it may be the result of slip movements as suggested in Fig. 4. Further investigations into this phenomenon are being made.

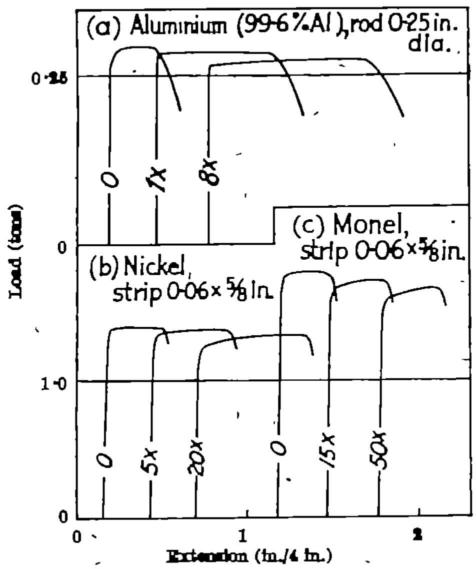
## Softening of Cold-worked Metals under Cyclic Strains

It is well known that ductile metals in the soft condition work-harden progressively when subject to cyclic straining, for example, in fatigue testing. On the other hand, I have shown[1] that metals originally cold-worked soften when plastically deformed under conditions in which a Bauschinger effect is operative. Since a Bauschinger effect is to be expected whenever the original and superimposed methods of deformation differ, it can be anticipated that initially cold-reduced metals may soften when later exposed to cyclic plastic strains. This is confirmed by the following experiments (see graph).

Diagram (*a*) refers to a rod initially cold-drawn 15·6 per cent, and in the as-drawn condition extension curve *O* was obtained. After an additional single reversed torsion cycle of 0 ± 45° per in. of length, the extensometer record altered to 1 ×, and after eight such cycles curve 8 × was recorded.

The nickel and Monel strips (*b*, *c*) were first cold-rolled 20 per cent and afterwards bent forwards and backwards over a 4-in. diameter cylinder. Curves 0 refer to the as-rolled condition. The others were obtained after subjecting the strips to the indicated numbers of reversed bending cycles.



Effect of reversed torsion cycles (*a*) and reversed bending (*b*, *c*) on tensile properties of certain cold-worked metals

There was a fall of surface hardness, yield and tensile values in each case, and a pronounced increase of elongation in most cases. Similar results were obtained with copper and carbon steel and for initial reductions up to 60 per cent (to be reported in detail elsewhere). Relevant effects noted in industrial straightening of rod and wire[2] can thus be accounted for on a rational basis.

Thanks are due to Mr. H. W. G. Hignett (The Mond Nickel Co., Ltd., Birmingham) for presenting samples of nickel and 'Monel' metal.

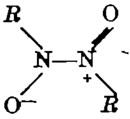
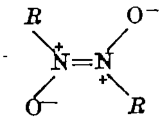
## Perfluoroalkyl Nitroso Compounds

A preliminary study[1] of the photochemical properties of the first fluorocarbon iodide, trifluoroiodomethane, showed that a trifluoromethyl radical is produced the primary reactions of which parallel those of the hydrocarbon free radicals. A direct method thus became available for the preparation of perfluoroalkyl nitroso compounds, by irradiation of the iodide in the presence of nitric oxide and of mercury (to remove iodine), with the difference that the product would then be stable, in contrast to alkyl nitroso compounds, which dimerize, and re-arrange to form oximes[2]. (Ruff and Giese[3] had previously reported as a by-product of the action of elementary fluorine on silver cyanide containing the oxide and nitrate as impurities, a 1 : 1 mixture of $CF_3NO$ and $FCONF_2$, from which the former could not be separated. Some properties and reactions were recorded, not all of which agree with the present work, or with what one would expect of the compound perfluoroformamide.)

Assuming, as seems likely, that the aliphatic nitroso compound dimers have the same constitution as their aromatic analogues, the structures of which are known[4], dimerization would here be inhibited by the strong inductive pull of the perfluoroalkyl group (cf. Pauling's adjacent charge rule[5]), and isomerization to form the aldoxime analogue would be impossible with the electronegative fluorine replacing hydrogen.



(two forms), with some contribution from



Perfluoro-1-nitrosopropane has been made by irradiating gas mixtures, at just below atmospheric pressure, of perfluoro-*n*-propyl iodide and nitric oxide (with a slight excess of the latter) in a silica bulb of 220 c.c. capacity containing about 5 c.c. of mercury. Osram high-pressure mercury vapour lamps (type *MB/V*, 125-watt, with the glass envelope removed) were used as sources of ultra-violet light. Purification of the gas was found to be difficult, but was effected by repeated distillation in a Fenske-packed column, with reflux temperature − 78·5°, middle cuts being taken. The pure nitroso compound, obtained in *c.* 80 per cent yield from the iodide, is a gas of very deep blue colour tinged with green; the liquid is deep blue, and the solid almost purple.

Preliminary values for the physical constants were measured on samples of which the molecular weight, determined by the gas density method, was within 1 per cent of 199, the theoretical value.

Saturation vapour pressures are given by

$$\log P\ (\text{mm.}) = 9{\cdot}035 - 1{,}593/T,$$

according to which the boiling point (extrapolated) is − 14·5° C., the latent heat of evaporation at the boiling point 7,270 cal., and the Trouton constant 28, suggesting that the liquid is strongly associated. The melting point was determined in a Stock apparatus as − 151° C. Analysis by the calcium fluoride method, after sodium fusion, gave 66·1 per cent fluorine (theoretical value, 66·8 per cent).

The spectrum of the gas was measured at room temperature, with a transmission-reading Cary recording spectrophotometer. The vapour was contained in a 4-cm. silica cell, filled to pressures between 5 and 75 cm. of mercury.

The blue colour of the gas is due to a very weak absorption band, for which $\varepsilon_{\text{max.}} = 19{\cdot}0$ at 6840 A., of oscillator strength (*f*-value) 0·00020 in the red. This band is markedly asymmetrical, but apart from six irregularly spaced and very poorly resolved vibrational bands, is almost structureless. The following are representative of the spectral slit-widths used in this region: 45 A. at 7000 A., 17 A. at 6500 A., 7 A. at 6000 A.

A region of more intense absorption begins at 2400 A. Between these two chief band systems there was invariably very weak banded absorption ($\varepsilon$ less than 0·2), the intensity of which varied from sample to sample, and which is therefore confidently ascribed to small and variable quantities of impurity.

This spectrum closely resembles that of di*iso*propyl bromonitrosomethane given by G. N. Lewis and M. Kasha[6] over a similar range, and those of other α-substituted aliphatic nitroso compounds observed in the visible region by D. Ll. Hammick *et al.*[7].

The liquid, in a sealed tube at room temperature, was found by the Gouy method to be diamagnetic (cf. nitrosyl chloride[8,9], nitrosobenzene[10]), and the molecular susceptibility agrees, within an experimental error of some 5–10 per cent, with the sum of the atomic susceptibilities (− 102 × $10^{-6}$ c.g.s.u.). The magnetic and optical properties support the formulation of $C_3F_7NO$ as a nitroso compound, in a singlet state[4,5,11].

The perfluoroalkyl nitroso compounds are readily oxidized, and are completely absorbed in alkali. Further studies of these compounds are in progress and will be offered for publication elsewhere.

I wish to thank Dr. I. G. Ross for measuring and commenting on the spectrum, Imperial Chemical Industries, Ltd. (General Chemicals Division), and the Minnesota Mining and Manufacturing Company, St. Paul, Minnesota, for gifts of fluorochemicals, and members of the Department of Chemistry (including Dr. N. Kornblum) at University College for help and encouragement.

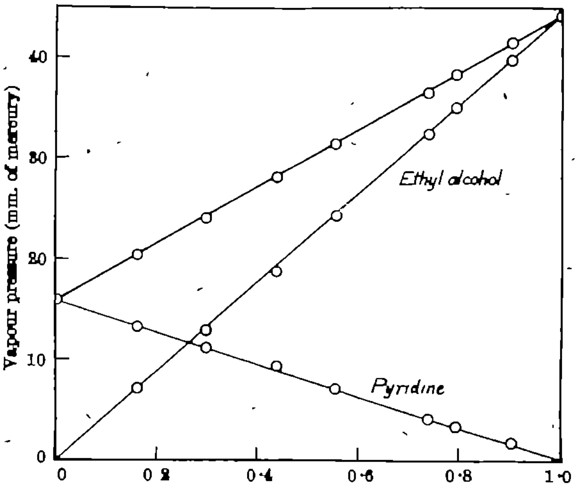
## Raoult's Law: a Pseudo-Ideal System

RELATIVELY few binary liquid mixtures obey Raoult's law in their vapour pressure relationships. Most of those which do so are mixtures of either isomers or close homologues. The components of the remainder are not, in general, highly polar substances[1].

In the course of other investigations, we have had occasion to measure the total and partial vapour pressures at 20° of the system pyridine – ethyl alcohol. The results (see graph) approximate closely to the behaviour required by Raoult's law. In this system, however, not only is association of one component (ethyl alcohol) possible, but also there can be intermolecular attraction, by hydrogen-bonding, between the two components. Evidence that such hydrogen-bonding does occur (to give a 1 : 1 molecular compound) is provided by the Raman spectra of the mixtures and the ultra-violet spectra of their solutions in non-polar solvents[2].

The only other results in accordance with Raoult's law from appreciably polar components of which we



Total and partial vapour pressures in the system pyridine–ethyl alcohol are aware are from an isobaric investigation of the system pyridine – acetic anhydride[3]. Here, however, there is no free hydrogen atom to allow of the extensive hydrogen-bonding which can occur between pyridine and ethyl alcohol.

It is interesting to note that the total pressure curves for the system pyridine – ethyl alcohol at 0° and at 40° show no deviation from linearity, within the limitations of the method used[4].

## Moving-Boundary Electrophoresis of Colloidal Electrolytes using Concentration Boundaries

OWING to the difficulty of finding sufficiently slow indicator ions, it is doubtful if the direct moving-boundary method for transference numbers can be fully applied to solutions of colloidal electrolytes. Hartley's 'balanced' boundary method[1], in which the colloidal ion forms the indicator ion, involves the determination of 'Kohlrausch concentrations' and a knowledge of the transference number of the leading ion.

The differential method, in which a boundary is formed between two concentrations of the same electrolyte, reveals the change in transference number between these concentrations across the boundary. Smith[2] and Longsworth[3] have shown that the transference number increments thus obtained with ordinary salts agree well with those from the direct moving-boundary method.

We have applied this to potassium laurate and lauryl sulphonic acid solutions at 0·5° C. For potassium laurate solutions, an excess of 4 equiv. per cent of potassium hydroxide on the basis of soap was added in the concentrated solution to prevent hydrolysis. The concentration of potassium hydroxide in the dilute solution was kept the same as in the stronger solution to prevent a concentration boundary due to potassium hydroxide. A Tiselius electrophoresis apparatus (Perkin Elmer Model 38 [4]), utilizing a 2-c.c. Tiselius cell and Longsworth's scanning method for photographing boundaries, was employed.

Preliminary results have been obtained with the 'open' electrode system and are reported in this communication. For accurate determination of the transference number increment over the interval $\Delta C$ across the boundary, however, the boundary displacements need to be measured with reference to a plane fixed with respect to the solvent. This is best accomplished by closing one electrode chamber, so that volume changes on this side alone affect the disposition of the boundaries. The necessary volume corrections may then be applied with a knowledge of the partial molal volumes of the electrolyte solutions. The determination of partial molal volumes of potassium laurate and laurylsulphonic acid solutions is in progress. The results described here are, however, of interest in that concentration boundaries have been used for the first time to investigate 'association' colloids.

Three concentration boundary systems were investigated for potassium laurate solutions. (1) Both solutions were below the critical concentration for micelle formation. The boundaries in the two limbs of the Tiselius cell moved towards each other irrespective of the direction of current. This was possibly due to convective flow caused by a great disparity of heat generated in the two solutions across the boundary. Similar phenomena have been observed by Smith[2] and Longsworth[3] with concentration boundaries involving simple electrolytes. (2) The dilute solution was fixed at a concentration ($\sigma''$) of 0·25 per cent and the concentrated solution ($\sigma'$) varied from 0·7 to 2·00 per cent. The anion transference number increment ($T_{\sigma'} - T_{\sigma''}$) showed a sharp rise when $\sigma'$ exceeded the critical concentration for micelle formation. (3) The concentrated solution was fixed at 2·0 per cent and the dilute solution varied from 0·25 to 1·50 per cent. The boundaries moved in the opposite direction to the positive current and the anion transference number increment ($T_{\sigma'} - T_{\sigma''}$) showed a maximum in the region of $\sigma''$ (equal to critical concentration for micelle formation).

Further experiments were carried out with boundary systems in which the dilute solution was fixed at a concentration corresponding to the critical concentration for micelle formation, being 0·83 per cent (0·035 *M*) and 0·25 per cent (0·010 *M*) for potassium laurate and laurylsulphonic acid solutions, respectively[4].

These boundary systems have a special significance in that the increments of anion transference number thus obtained represent the transport due to the associated colloid ion or ions. The anion transference

Potassium laurate solutions. (*A*) 3·00–0·83 per cent; 1,200 sec. (*B*) 3·00–0·83 per cent; 1,800 sec. (*C*) 2·00–0·83 per cent; 1,800 sec. (*D*) 2·00–1·00 per cent; 1,200 sec.
Laurylsulphonic acid solution. (*E*) 2·00–0·25 per cent; 1,200 sec. (*F*) 0·75–0·25 per cent; 1,200 sec.

number increment ($T_{c'} - T_{c.m.c.}$) passed through a maximum at $c' = 3{\cdot}0$ per cent ($0{\cdot}126\ M$) for potassium laurate and at $c' = 1{\cdot}5$ per cent ($0{\cdot}060\ M$) for laurylsulphonic acid solution[6]. These maxima correspond to concentrations at which the solutions have reached the fully colloidal state as shown, for example, by the solubilization of dyes by aqueous potassium laurate and laurylsulphonic acid[7].

The schlieren patterns obtained are of interest. There is a sharpening effect at the descending boundary which moves as a steady state almost from the moment the current is switched on. There is a spreading effect at the ascending boundary which splits into two component boundaries. This may, or may not, be due to the presence of more than one kind of colloidal particle. A few representative ascending patterns are illustrated in the accompanying photographs. It may be noted that the area under the faster component of the ascending pattern remains practically unchanged for either electrolyte over a considerable range of concentration. If, however, the concentration of the dilute solution across the boundary were increased from 0·83 to 1·00 per cent (for potassium laurate solutions), the faster boundary disappeared (compare patterns *C* and *D*). The faster boundary of the ascending pattern may therefore be due to a rapid increase of anion transference number over a narrow range of concentrations just above the critical concentration for micelle formation.

I am grateful to Prof. J. W. McBain and Dr. S. S. Marsden for their interest in this work.

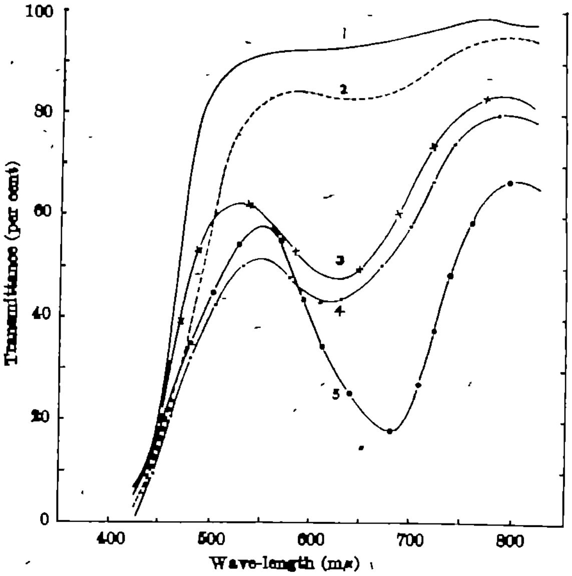
## Interference of Pentose in the Estimation of Hexose Sugars with Anthrone

IN the course of investigations on methods for the determination of sugars in the study of the trashy leaf phenomenon in Australian flue-cured tobacco[1], it was soon apparent that the anthrone reagent of Dreywood[2] was well suited to the routine estimation of hexose and polyhexose sugars in plant materials. It was found, however, that the quantitative estimation of sugars with anthrone requires rigid control of variables such as the rate of evolution of heat of hydration of sulphuric acid in the development of the green-coloured sugar–anthrone complexes.

It has now been found that pentose sugars may interfere appreciably in the determination of hexoses. This matter could be of some importance in view of the extensive use of anthrone in estimating hexose and polyhexose sugars in biological materials[3]. The colour intensity of the pentose–anthrone complex is negligible compared with that of the hexose–anthrone complex, when sugars are compared individually on an equimolecular basis. Anthrone might therefore be regarded as virtually specific for hexose and polyhexose sugars when applied to separate test solutions. This specificity does not apply when pentose and hexose are present in the same solution.

Absorption curves have been determined for analytical grade purity and recrystallized laboratory reagent hexose, dihexose and pentose sugars (that is, glucose, fructose, sorbose, sucrose, xylose, arabinose and ribose) and for pentose plus hexose solutions anthronated before and after mixing. Curves 1, 2 and 3 of the accompanying figure are typical spectral curves for anthrone reagent alone, pentoses (arabinose 100 μgm. per 12 ml.) and hexoses (glucose 50 μgm. per 12 ml.) respectively. Curve 4, typical for mixtures of pentoses and hexoses, was obtained when equal volumes of separately anthronated solutions of arabinose (200 μgm. per 12 ml.) and glucose (100 μgm. per 12 ml.) were cooled to 20° C. and mixed just before spectral measurements. Curve 5 was obtained when the pentose–hexose solutions were mixed before anthronation. The standard anthronation procedure adopted in this laboratory was followed in all cases. The spectral measurements were made on a Beckman spectrophotometer (model *D.U.*), and the coloured complexes obtained proved stable at room temperature, with no perceptible colour deterioration within 60 min. Curve 4 for the mixture of separately developed pentose–anthrone and hexose–anthrone complexes follows closely that of the hexose–anthrone complex (curve 3), with minimum transmittance at about 625 mμ, and appears to be the resultant of the two curves; whereas curve 5 (pentose–hexose–anthrone), obtained with the mixed sugars, differs markedly and shows maximum absorption at about 680 mμ. It is clear that, when pentoses and hexoses are anthronated together, a complex is formed of a very different nature from that formed when hexoses are anthronated alone.

The accompanying table presents values for glucose estimated by the anthrone technique in known mixtures of glucose with arabinose, using a Hilger absorptiometer with a filter of 620 mμ maximum transmittance. The 'error' expected from the inclu-



Absorption curves for sugar–anthrone complexes. (1) ———, anthrone reagent only; (2) - - - - -, arabinose, 100 μgm. per 12 ml.; (3) —×—×, glucose 50 μgm. per 12 ml.; (4) ——·——, mixture of separately anthronated solutions containing complexes of 100 μgm. arabinose and 50 μgm. glucose in 12 ml.; (5) —○—○, complex of anthronated solution containing 100 μgm. arabinose and 50 μgm. glucose in 12 ml.

INTERFERENCE BY PENTOSE IN ESTIMATION OF HEXOSE SUGARS WITH ANTHRONE

| Mixture of | | Glucose found* (µgm.) | Error found expressed as glucose (µgm.) | Approximate error expected† (µgm.) |
|---|---|---|---|---|
| Arabinose (µgm.) | Glucose (µgm.) | | | |
| 0 | 30 | 30 | 0 | — |
| 25 | 30 | 37 | 7 | < 1 |
| 25 | 60 | 67 | 7 | < 1 |
| 50 | 60 | 74 | 14 | < 2 |
| 100 | 60 | 88 | 28 | < 4 |
| 100 | 90 | 120 | 30 | < 4 |
| 100 | 120 | 154 | 34 | < 4 |
| 150 | 120 | 171 | 51 | < 6 |

* Values read off a standard glucose graph. They are means of four separate estimates, each based on two duplicates. The 95 per cent confidence limits to these means are given by mean ± 1·2 per cent of the mean.

† Absorption readings for various amounts of anthronated pure arabinose read off the standard glucose graph and expressed as glucose

sion of the arabinose was determined by measuring the colour development from a pure arabinose solution, and expressing this in terms of glucose. It was found that 100 µgm. of arabinose gave a colour development equivalent to less than 4 µgm. of glucose. The errors actually observed in solutions containing both sugars were far greater than this, approaching 30 per cent when the molecular concentration of arabinose equals that of glucose.

This finding indicates that, when using the hexose–anthrone complex in hexose sugar estimation, any pentoses present should be corrected for or removed. The procedure adopted for separation of pentose and hexose sugars from their mixtures, and the quantitative estimation of both groups, will be published elsewhere.

## Liesegang Rings on Metallic Bases

WE have repeated the experiment described by Christomanos[1], and observe the formation of good Liesegang rings in all cases on clean, pure silver and other more noble metals; but either no rings, or badly distorted ones, on less noble metals and silver alloys. If the silver surface is previously darkened by exposure to sulphide, the rings are distorted but none the less appear in most cases. If, however, the clean metal is previously heated to darkening, or dipped in hydrogen peroxide solution, the rings that are eventually formed are decidedly inferior.

These observations suggest a modification of the normal ring formation by interruption of the straightforward precipitation of silver chromate, and appear to be compatible with the supersaturation theory rather than requiring an electrochemical explanation.

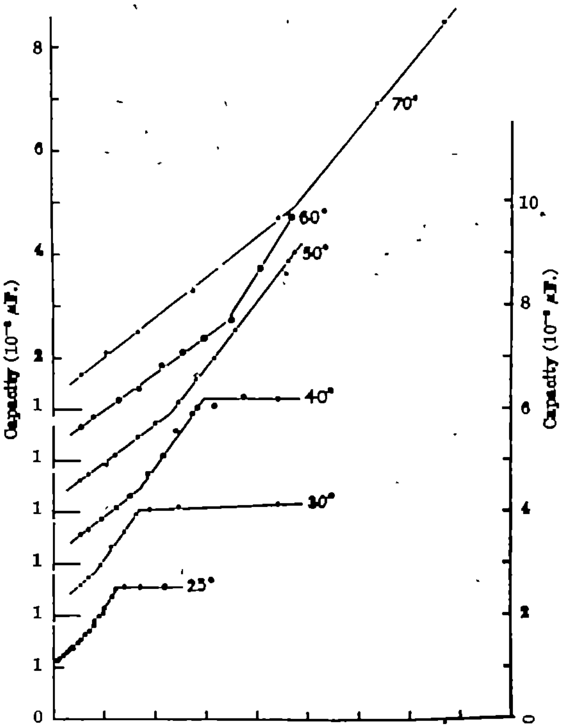
## Effects of Water Vapour on the Electrical Properties of Anodized Aluminium

IN connexion with experiments on semiconductors, one of us[1] noted the very considerable change of capacity which took place when a condenser containing aluminium oxide as the dielectric material was placed in a system which was then evacuated. The change of capacity was ascribed to the removal of adsorbed water from the porous aluminium oxide. In the above investigation, the condenser consisted of an aluminium sheet, of an aluminium oxide layer formed electrolytically (by 'anodizing') on the sheet, and of a thin metallic layer of aluminium evaporated on to the oxide film. The aluminium sheet and the evaporated surface then formed the plates of the condenser.

We measured the capacity of a condenser formed in a similar fashion on an aluminium wire of commercial purity, of approximately 1/16 in. diameter, which was placed in an enclosure in which water vapour was admitted under controlled conditions. Some measurements of the leakage resistance of the condenser were made concurrently with the capacity measurements. A typical sample of useful length 3 cm. had a capacity of 1,200 pF. at zero humidity. The oxide layer was formed at 50 V. in a 3 per cent chromic acid bath. The thickness of the oxide film is estimated to be about 1 micron.

A family of curves relating the capacity of the condenser to water vapour pressure at various temperatures of the condenser is shown in the accompanying graph. Several features are worthy of comment: (1) each curve may be represented by two intersecting straight lines; (2) the initial



Variation of capacity with water vapour pressure in the enclosure for various temperatures of the element. (For clarity, the capacity ordinate of successive curves has been displaced one unit vertically) straight line is in each case the same; (3) the maximum capacity is attained when the measured vapour pressure corresponds to the saturation vapour pressure at the temperature of the condenser; (4) the slope of each curve changes sharply when the vapour pressure approximates to half the saturation vapour pressure at the temperature of the condenser; (5) the slope of the second portion of each curve is almost identical.

The results for each set of points may be expressed in a non-dimensional form:

$$R_c = 0{\cdot}73\,R_H \qquad \text{when } 0 < R_H < 0{\cdot}5 \quad 1(a)$$

$$R_c = 1{\cdot}12\,R_H - 0{\cdot}18 \qquad \text{when } 0{\cdot}5 < R_H < 1 \quad 1(b)$$

where $R_c$ is the change of capacity relative to the maximum change of capacity (that is, at the saturation vapour pressure) and $R_H$ is the relative humidity.

The leakage resistance, $R$, of the aluminium oxide at 50° C., 60° C. and 70° C. was found to decrease exponentially with increasing water vapour pressure, $p$. In each case the relationship can be expressed by the equation:

$$R = R_0 \exp\,(-\,p/p_0), \qquad (2)$$

where $R_0$ is the resistance at zero vapour pressure and $p_0$ is a constant at a given temperature. The accompanying table gives the value of the parameters $R_0$ and $p_0$ in (2) for the three temperatures at which these investigations were carried out.

| Temperature (° C.) | $R_0$ ($10^7$ ohms) | $P_0$ (mm. mercury) |
|---|---|---|
| 50 | 940 | 13·0 |
| 60 | 93 | 36·5 |
| 70 | 2·95 | 118 |

Preliminary experiments have shown that the capacity element is also sensitive to the vapours of most other substances, and that the magnitude of the effect is related to the saturation vapour pressure and to the dielectric constant of these substances.

It is believed that the effects briefly described above will have many applications in addition to the measurement and control of humidity[2]. Further work is being carried out and a more detailed account will be given elsewhere.

## Effects of Methyl *bis* (beta-Chloroethyl) Amine Hydrochloride on Haploid and Diploid Embryos of *Habrobracon*

X-RADIATION of the parasitic wasp, *Habrobracon*, has shown that haploids and diploids are differentially radiosensitive. During the larval, prepupal and pupal stages, diploids are more resistant than haploids[1]. During the cleavage stages of the embryo, however, haploids are more resistant than diploids, and immediately after cleavage, haploids and diploids are equally sensitive to X-rays[2]. Some of the mustard compounds are highly mutagenic and cause chromosome breakage[3]. We decided, therefore, to test the effects of the nitrogen mustard, methyl *bis* (beta-chloroethyl) amine hydrochloride on haploid and diploid embryos of *Habrobracon*.

In *Habrobracon*, haploids develop from unfertilized eggs and diploids from fertilized eggs. Haploid cultures are obtained from unmated females, whereas cultures containing both haploid and diploid eggs ('mixed cultures') are obtained from mated females. Normally, about 65 per cent of the eggs from mated females are fertilized and, accordingly, are diploids. In material used in the present report, all haploids develop into males and all diploids into females. Eggs stored in the uterine sacs of the females remain in first meiotic metaphase, and further development does not take place until the eggs are laid[4]. It is therefore easy to obtain embryos of known stages.

Eggs were placed in bags made of lens paper and immersed in solutions of nitrogen mustard for half an hour. The nitrogen mustard solution was made up immediately before use and was kept at pH 7 by means of the Teorell buffer. Kolmark and Westergaard[5] have shown that the toxic action of the nitrogen mustard on *Neurospora* is dependent upon pH, temperature, concentration, and age of the solution. We have found (unpublished experiments) that these same factors have a marked effect on the hatchability of eggs of *Habrobracon*. Embryos after treatment were washed in a glycine – sodium bicarbonate solution to stop the reaction of the compound and then in distilled water. Afterwards, they were either (*a*) placed in a mineral oil and the incidence of hatchability obtained, or (*b*) placed upon their host (*Ephestia* larva) and the incidence of adult males and females obtained.

Embryos in the cleavage stage were immersed in the nitrogen mustard solution. On the basis of hatchability, the haploid plus diploid cultures (mixed cultures) (0·222 ± 0·014) were much more affected than were the haploid cultures (0·581 ± 0·017) (Table 1). Treated embryos from mated females were permitted to develop into adults in order to determine the incidence of haploids (males) and diploids (females). Of the treated embryos, 22 per cent hatched and most of these developed into adults. There is a significant difference in the incidence of females from treated embryos (0·231 ± 0·037) and the females from controls (0·643 ± 0·020) (Table 2). These results show that haploid males are much more resistant than diploid females when treated during the cleavage stage. No such differential toxic effect was noted between haploids and diploids treated at later embryonic stages.

Table 1. HATCHABILITY RATIOS FOR EGGS FROM MATED AND UNMATED FEMALES TREATED WITH NITROGEN MUSTARD (0·001 PER CENT)
(Eggs treated during the Cleavage Stage)

| | From mated females (haploid + diploid) | | From unmated females (haploid) | |
|---|---|---|---|---|
| | No. eggs | Hatchability | No. eggs | Hatchability |
| Controls | 286 | 0·944±0·014 | 217 | 0·967±0·012 |
| Treated | 878 | 0·222±0·014 | 837 | 0·581±0·017 |

Table 2. SEX RATIOS OF ADULTS FROM EGGS OF MATED FEMALES TREATED WITH NITROGEN MUSTARD (0·00075 PER CENT)
(Eggs treated during the Cleavage Stage)

| | No. adults | No. ♂♂ | No. ♀♀ | ♀♀ / Total adults |
|---|---|---|---|---|
| Controls | 560 | 200 | 360 | 0·643±0·020 |
| Treated | 130 | 100 | 30 | 0·231±0·037 |

When eggs are treated during cleavage, the effects of the nitrogen mustard are apparent prior to hatching, and those that hatch develop normally into adults. Embryos treated in late stages of development, however, even though they may hatch, are arrested in the larval or pupal stages. Haploid embryos that were treated with nitrogen mustard during cleavage were fixed at a stage when somites would normally be present and stained with the Feulgen reagent. Microscopical examination showed that these embryos had been arrested in cleavage. The nuclei and nucleoli were greatly enlarged and mitosis was halted at interphase. The same effects reported here were obtained with X-rays[3].

Differential effects of chemical agents on individuals differing in the number of chromosome sets have been reported by other investigators, although not with the view of correlating their findings with mutagenesis. Fankhauser[6] showed that young pentaploid larvæ of *Triturus viridescens* are more susceptible to chloretone than are diploid larvæ. Briggs[7] treated androgenetic haploids and normal diploids of *Rana pipiens* before or after gastrulation with hexenolactone. He found no differential effects during pre-gastrula development, but treatment after gastrulation showed that haploids were more sensitive. Hexenolactone has been found to be effective in stopping early cleavage[7]. Smith and Srb[8] have shown that a closely related substance, beta-propiolactone, induces mutations in *Neurospora* and causes chromosomal aberrations in *Vicia faba*.

These results show certain similarities between the effects of methyl *bis* (beta-chloroethyl) amine hydrochloride and of X-rays upon haploids and diploids of *Habrobracon*. Studies in progress on mutagenic and non-mutagenic substances should determine to what extent a differential effect upon haploids and diploids can be used to distinguish substances that are mutagenic and/or cause chromosomal aberrations.

The methyl *bis* (beta-chloroethyl) amine hydrochloride was kindly furnished by Merck and Co., Inc. This work was done under contract No. *AT*(30-1)-953 for the United States Atomic Energy Commission.

## Inhibition Effects in Back-Mutation Tests with Mutants of *Neurospora*

THE observation of Grigg[1] that large numbers of conidia of biochemically deficient mutant strains of *Neurospora crassa* strongly inhibit the growth of 'wild-type' conidia when plated on minimal medium containing 0·2 per cent sucrose and 0·4 per cent sorbose led him to question the validity of back-mutation tests. On the other hand, Kølmark and Westergaard[2] have reported that in comparable experiments (using an adenine mutant *W* 40) the substitution of a minimal medium containing 2 per cent glucose completely abolishes the growth inhibition. They suggest that the inhibition of 'wild-type' conidia on sorbose medium results from a removal by the large population of germinating mutant spores of the limited amount of sucrose available; they conclude, therefore, that the growth inhibition has no relation to back-mutation tests as usually conducted.

In connexion with our own studies of chemical mutagenesis[3], we have tested a number of mutant strains to ascertain whether this inhibition phenomenon may affect our tests of mutagenic activity. Biochemically deficient, colonial (70007), macroconidial mutants (induced by mustard-type compounds) were tested for their capacity to inhibit growth of wild-type macroconidia carrying the colonial gene (70007). In reconstruction experiments[1] using a minimal medium containing 1·5 per cent sucrose or 2 per cent glucose, a *p*-aminobenzoic acid mutant *WSC* 4-176 (*paba*) and a leucine mutant *WSC* 7-267 (*leuc*) were found to inhibit the growth of colonial conidia. As shown in the accompanying table, pronounced inhibition occurs under conditions commonly employed in back-mutation tests. Not only was the number of colonies decreased in the presence of the mutant, but the colonies were also smaller and many appeared a day or two later. An inositol mutant 37401 (*inos*), as previously observed[4], showed no inhibitory effect. Comparable experiments have been carried out using, in place of colonial (70007) conidia, *paba*+ and *leuc*+ strains isolated from back-mutation experiments with mustard-type compounds. These strains were also inhibited by mutant conidia (see table). Doubling the concentration of the constituents of the minimal medium did not affect the inhibition of colonial by mutant conidia, but if the minimal medium was supplemented by a mixture of amino-acids and vitamins, inhibition was decreased in the case of the *leuc* mutant.

EFFECT OF MUTANT CONIDIA ON GROWTH OF NUTRITIONALLY INDEPENDENT STRAINS OF *Neurospora*

| Mutant strain used | No. of mutant conidia (per plate) | Nutritionally independent conidia used | Average inhibition of nutritionally independent conidia (per cent) |
|---|---|---|---|
| *paba A* | $7 \times 10^6$ | colonial *a* | 30 |
| " | $7 \times 10^6$ | colonial *A* | 65 |
| " | $7 \times 10^5$ | colonial *A* | 20 |
| " | $7 \times 10^6$ | *paba*+ (heterocaryotic) | 30 |
| " | $8 \times 10^5$ | | 0 |
| " | $7 \times 10^6$ | *paba*+ (homocaryotic) | 70 |
| " | $7 \times 10^5$ | " | 0 |
| *leuc A* | $8 \times 10^6$ | colonial *A* | 45 |
| " | $8 \times 10^6$ | *leuc*+ (homocaryotic) | 55 |
| *inos A* | $8 \times 10^6$ | colonial *A* | 0 |

The growth inhibition by different mutant strains can also be demonstrated using a 'half-plate' method. In this technique the suspension of mutant conidia is spread over one-half of the surface of minimal medium in a Petri-dish, allowed to dry for a few hours, and colonial conidia added at a point at the border-line; radial growth is then measured in both directions. The 'giant' colonies grew unilaterally away from the side on which the *paba* or *leuc* mutant had been spread, but no such inhibition was observed with the *inos* mutant. Two cytidine mutants (*WSC* 7-168 and *WSC* 5-25), a cystine mutant (*WSC* 7-303) and a purple adenine mutant (*WSC* 5-298) were found to inhibit colonial growth in varying degrees.

Although both the inhibitory and non-inhibitory types of mutant germinate on minimal medium, experiments indicate that they do not survive equally well in the absence of added supplement. Mutant conidia were plated out in dilute solution (20–200 conidia per plate) on minimal medium, and the compound required by the respective mutant added after a specified number of days. No colonies of the *inos* mutant survived after two days; in contrast, in the case of the mutants which produce growth inhibition, a large proportion of the colonies survived even after six days on minimal medium.

The demonstration of the inhibition of growth of colonial conidia by conidia of certain mutant strains under conditions commonly used in back-mutation experiments reopens the question to what extent this phenomenon affects such results. Grigg suggests the possibility that the back-mutants supposedly induced by the mutagen are already present in the population of untreated conidia but are inhibited either by the large numbers of mutant conidia present or by an intraconidial effect of mutant nuclei. The mutagen, by virtue of its toxicity, would then appear to produce back-mutants simply by killing off inhibiting mutant cells or nuclei. Dilution experiments similar to those described by Grigg[1] were performed with the *paba* and *leuc* mutants. In no case did extra *paba*+ or *leuc*+ colonies appear as a result of plating the mutants at lower concentrations. As a further test, conidia of the mutant strains were treated with a nitrogen mustard, $(C_6H_5CH_2)_2NCH_2CH_2Cl$, which in previous experiments[2] had shown negligible mutagenic activity. In a total of eighteen experiments with *paba* and *leuc* mutants, in which the mortality ranged from 30 to 98 per cent, no induced mutation-rate was recorded. These results provide evidence that, with the particular mutant strains tested, the suggestion of Grigg does not apply. It seems probable that, depending on the nature of the particular mutant employed, the growth inhibition of wild-type by mutant conidia can result in apparent mutation rates which are either higher or lower than the true values.

This work was supported in part by a fellowship to one of us (A. M.) from the Washington Division, American Cancer Society, and in part from funds for biological and medical research, State of Washington Initiative Measure 171.

## Auxins and Auxin Precursors in Plants

The principal auxin in higher plants is generally believed to be indoleacetic acid, which is supposed to arise from tryptophane (*a*) *via* indoleiminoacetic acid, indolepyruvic acid and indole acetaldehyde, or (*b*) *via* tryptamine and indole acetaldehyde[1]. The general occurrence of tryptophane in the plant kingdom is well established. Indoleacetic acid has been isolated from seeds; White[2] found tryptamine in *Acacia*; and there is considerable indirect evidence for the occurrence of indole acetaldehyde in pea, pineapple and potato. Synthetic indolepyruvic acid and tryptamine can be converted to indoleacetic acid by certain living plant tissues and enzyme preparations made from them; but the actual function of either of these substances as an intermediary in the biosynthesis of indoleacetic acid from tryptophane has not been proved.

Since certain crude enzyme preparations are able to convert tryptophane and some of the suggested intermediaries to auxin, they may be used as means for detecting naturally occurring intermediaries in the biosynthesis of indoleacetic acid. In experiments carried out at the Department of Botany, University of Chicago (supported in part by a grant from the Dr. Wallace C. and Clara A. Abbott Memorial Fund of the University of Chicago), it was found by Bonde[3] that ether extracts of pea internodes contained no active neutral growth-substance if the extraction was made at 0° C., whereas extracts made at 22° C. contained an abundance of neutral growth-substance, presumably indole acetaldehyde, active in the *Avena* curvature test. It was assumed that this neutral growth-substance was formed during the extraction at the expense of precursors which might possibly be present in the extracts made at 0° C. Various fractions of such extracts, therefore, were treated with fresh coleoptile juice as a source of conversion enzyme. The acid and non-acidic fractions were examined in the *Avena* curvature test. The tests showed that the non-acidic fraction, originally inactive itself, contained an acid growth-substance, presumably indoleacetic acid, after treatment with coleoptile juice. This result indicates the presence in the original extract of a non-acidic precursor of indoleacetic acid. The formation of a neutral growth-substance (indole acetaldehyde) could not be demonstrated, but the possibility of its intermediary formation is not excluded; the aldehyde may become very rapidly converted to the acid.

Similar experiments with the non-acidic fraction of juice exuded from the internode sections during the ether extraction yielded identical results. The acid fraction of the juice was active in the *Avena* test, but its activity increased gradually under the influence of coleoptile juice. These results indicate the presence in pea juice of both a non-acidic and an acid precursor of indoleacetic acid.

Juice exuded from the inner, etiolated leaves of heads of cabbage was treated in the same manner as juice from pea internodes. Again, the non-acidic fraction, originally inactive, yielded an acid growth-substance upon treatment with coleoptile juice. Cabbage juice, however, differed from the juice of pea internodes in that the acid fraction of the juice yielded a neutral growth-substance upon such treatment. These results indicate the presence in cabbage juice of a non-acidic precursor of indoleacetic acid as well as an acid precursor of the neutral growth-substance.

The acid auxin found in all these experiments is undoubtedly indoleacetic acid. The non-acidic precursor found in both ether extract and juice can scarcely be tryptamine because it behaved as a neutral substance, and not as a base, when partitioned between ether and water at either alkaline or acid reaction. The acid precursor present in the juice of pea internodes might be indolepyruvic acid.

Larsen[4] assumed the neutral growth-substance in heads of cabbage to be indole acetaldehyde. The assumption was based on the considerable amount of indirect evidence for the aldehyde nature of the neutral substance in pea (see also Gordon and Sánchez Nieva[5]), but no actual identification was attempted. Jones *et al.*[6] isolated indole acetonitrile from brussels sprouts. This compound is active in the *Avena* curvature test, the straight-growth test with coleoptile sections, and various other auxin tests. The nitrile is probably also present in heads of cabbage, but further experimentation will now be needed to determine whether or not indole acetaldehyde is present in addition. At present, it is impossible to say whether the above-mentioned acid precursor of a neutral growth-substance in cabbage juice is a precursor of indole acetaldehyde or of indole acetonitrile or both.

Jones *et al.*[6] placed sections of *Avena* coleoptiles in a solution containing 10 mgm. of indole acetonitrile per litre. After 20 hr. the solution contained an amount of acid growth-substance which, if computed as indoleacetic acid, was equivalent to about 1 per cent of the initial amount of nitrile. The amount of unconverted nitrile was not reported. This result, however, does not necessarily indicate that no more than 1 per cent of the nitrile has been converted to acid. As shown by Larsen[7], coleoptile sections inactivate indoleacetic acid very rapidly, and there can be little doubt that indoleacetic acid formed in the experiments by Jones *et al.* would become inactivated to a very considerable extent during the 20-hr. duration of the experiment. The production of indoleacetic acid in their experiments, therefore, may actually have been much higher than 1 per cent of the amount of added nitrile. Coleoptile juice does not inactivate indoleacetic acid and will probably be more suitable than living sections for demonstrating the capacity of *Avena* coleoptiles to convert indole acetonitrile to indoleacetic acid.

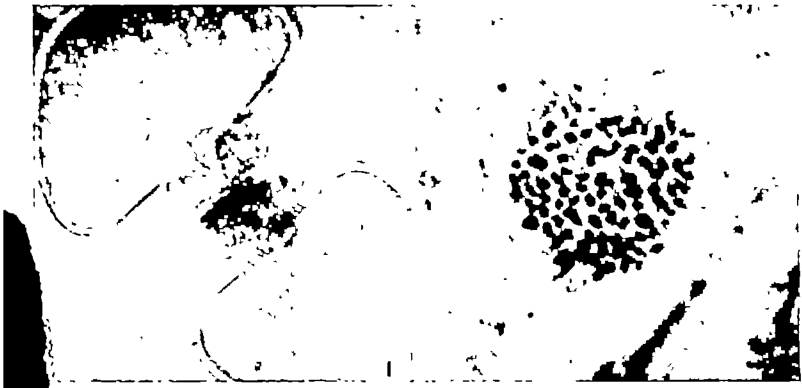
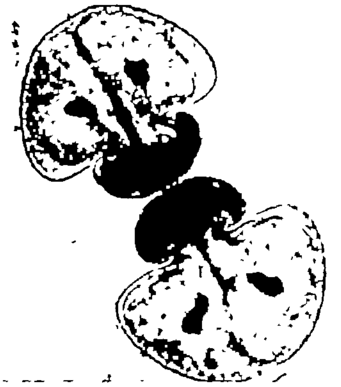
## 'Diffuse' Centromere, and other Cytological Observations on Two Desmids

Cytological studies of the Desmidiaceae now in progress in this department have shown that the chromosomes of *Cosmarium botrytis* and *Pleurotaenium kallis* have a polycentric or diffuse centromere type of organization, which results in the parallel separation of the chromatids at anaphase (Fig. 1). This type of organization has been previously described in *Spirogyra*[1], and among the higher plants in *Luzula*[2] and *Carex*[3].

The chromosome complement of *Cosmarium botrytis* is $n = 18$ and of *Pleurotaenium kallis*, $n = 104$. In the former, the chromosomes at metaphase are loosely joined together, so as to form one or more sinuous threads, while in the latter they are evenly distributed over the equatorial plane of the spindle (Fig. 2). In both, the spindle, like that of *Spirogyra*, is so truncated as to appear sub-rectangular in side view.





3

Fig. 1. *Cosmarium botrytis* showing the parallel separation of the chromatids at anaphase. × 1,100

Fig. 2. Polar view of the metaphase plate of *Pleurotaenium kallis*. × 1,350

3. *Cosmarium botrytis*. Discharge of nuclear material into the protoplasm of the developing semi-cell. Stain: iron aceto-carmine. × 475

The re-establishment of the resting nucleus after division in *Cosmarium botrytis* is peculiar in that the nucleus remains as a plate-like mass at the apex of the developing semi-cell, where it discharges, into the protoplasm of the new semi-cell, material which has a great affinity for iron (this material is presumably ribonucleic acid). So great is this discharge that, with staining, the contents of the semi-cell become obliterated by the intense coloration, which, however, grades off towards the isthmus (Fig. 3). Cells which have been only slightly stained show that at this stage the nucleus begins to migrate to the isthmus, where it is reformed. By this time the new semi-cell is almost fully grown. The re-formation of the resting nucleus at the isthmus goes hand in hand with the progressive loss of affinity for iron of the protoplasm.

# FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

## Monday, January 26

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. B. H. Farmer: "Problems of Land Use in the Dry Zone of Ceylon".

Physical Society, Acoustics Group (in Room 4, University College, Malet Place, London, W.C.1), at 5.15 p.m.—Mr. H. Aspinall and Mr. J. Y. Morton: "An Acoustical and Mechanical Impedance Measuring Set, and some Results of Measurements on Human Ears and Mastoids".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "The Relative Merits of Harmonic and Intermodulation Measurements in Assessing Distortion in Audio Equipment" (to be opened by Mr. H. W. Barth-Jones).

## Tuesday, January 27

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. D. M. Newitt, F.R.S.: "Experimenting at High Pressures". (Further Lectures on February 3 and 10.)

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Dr. R. Matalon. "Colloid Science and some of its Industrial Applications".* (Further Lectures on February 10, 24 and March 10.)

## Wednesday, January 28

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Dr. D. T. Germain-Jones: "Geophysics—its Problems and Trends".*

Institution of Electrical Engineers, Supply Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. A. F. B. Young: "Some Researches on Circuit-Breaking by means of High-Voltage Circuit-Breakers with special reference to Current-Chopping".

Illuminating Engineering Society (at the Royal Institution, 21 Albemarle Street, London, W.1), at 6 p.m.—Dr. E. D. Adrian, O.M., Pres.R.S.: "The Nervous Reactions of the Retina" (Trotter–Paterson Memorial Lecture).

Society of Chemical Industry, Nutrition Panel of the Food Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.15 p.m.—Dr. G. A. C. Herklots and Prof. J. Yudkin: "Food and the Future", 2: "Some Present-day Methods of Attack on the Problems of Food Production".

## Thursday, January 29

Royal Society (at Burlington House, Piccadilly, London, W.1), at 10 a.m.—Discussion on "V-Particles and Heavy Mesons" (to be opened by Prof. C. F. Powell, F.R.S.).

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 10.30 a.m.—Discussion on "Problems of Distribution of Animals and Plants in Africa".

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. D. M. Ross: "Scholarship and Practice in the History of Biology".*

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Dr. S. R. Nockolds: "Trace Elements in the Earth". (Further Lectures on February 5 and 12.)

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. John Wilks: "The Influence of R. W. Chambers on the Development of University Libraries" (Chambers Memorial Lecture).*

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Major P. Litherland Teed: "Titanium—a Survey".

Society of Public Analysts and other Analytical Chemists, Microchemistry Group (at the Sir John Cass College, Jewry Street, London, E.C.3), at 7 p.m.—Annual General Meeting; Dr. Cecil L. Wilson: "Microchemistry, an Appraisal".

## Friday, January 30

Institution of Mechanical Engineers (joint meeting with the Steam Group, at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. H. Hillier: "Scale Formation in Sea-Water Distilling Plants and its Prevention".

Royal Institute of Philosophy (at University Hall, 14 Gordon Square, London, W.C.1), at 5.30 p.m.—Mr. D. A. Rees: "Greek Views of Nature and Mind".

Society of Public Analysts and other Analytical Chemists, Physical Methods Group (in the Mason Theatre, The University, Edmund Street, Birmingham), at 6.30 p.m.—Discussion on "Chromatography".

University of London (at Westfield College, Kidderpore Avenue, Hampstead, London, N.W.3), at 7.45 p.m.—Very Rev. H. A. Jones: "The Scientist's Universe and the Christian's Faith".* (Further Lectures on February 13 and 20.)

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Harold Spencer Jones, F.R.S.: "The Mountains of the Moon".

## Saturday, January 31

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Miss Winifred M. A. Brooke: "The Bolivian Andes and its People To-day".*

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Experimental Officer at the Fuel Research Station, Greenwich—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.754/52A (January 31).

Scientific Officer (with a first- or second-class honours degree, or equivalent, in chemistry) with sound knowledge of electrochemistry and electrodeposition of metals, at a Ministry of Supply Establishment, Aldermaston—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.817/52A (January 31).

Assistant (with a university degree, preferably in economics or mathematics, and experience in operational research or similar work) in the Operational Research Section, Generation Operation Branch, headquarters Bankside—The Director of Establishments, British Electricity Authority, British Electricity House, Winsley Street, London, W.1, quoting Ref. AH.302 (February 2).

Head of the Department of Mechanical and Electrical Engineering—The Principal, Wigan and District Mining and Technical College, Wigan (February 2).

Meteorological Officers (with an honours university degree covering physics, mathematical physics or mathematics, or a university degree in meteorology, or an academic qualification equivalent to either) in the Department of Industry and Commerce, Dublin—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (February 3).

Scientific Officer (with a good honours degree, an interest in biological problems and, preferably, some research experience) in the Chemistry Department, to take part initially in researches on the chemistry of the milk proteins and enzymes—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 53/2 (February 7).

Biochemist (principal or senior grade) in the Group Pathological Department—The Secretary, South Worcestershire Hospital Management Committee, Royal Infirmary, Worcester (February 9).

Scientists (with honours degree or equivalent and a good know[illegible]ledge of at least one of the following subjects: physical metallurg[illegible] engineering metallurgy, including knowledge of machinery, to[illegible] materials, hard metals, etc., physical chemistry, corrosion) at t[illegible] Central Research Establishment, Isleworth, Middlesex—The Nation[illegible] Coal Board, Establishments (Personnel), Hobart House, Grosve[illegible] Place, London, S.W.1, quoting TT/578 (February 9).

Assistant Lecturer or Lecturer in the Department of Ci[illegible] Engineering—The Registrar, The University, Liverpool (Febru[illegible] 11).

Research Assistant in the Department of Anatomy, for w[illegible] mainly on central nervous system—The Secretary, University Coll[illegible] Gower Street, London, W.C.1 (February 13).

British Coke Research Association Fellowship tenable in t[illegible] Department of Coal Gas and Fuel Industries, for research at post[illegible]graduate standard on a subject connected with the coke industry—The Registrar, The University, Leeds 2 (February 14).

Lecturer in Pure Mathematics (preferably qualified in algebra and geometry)—The Registrar, University College, Singleton Park, Swansea (February 14).

Research Officer (with a University honours degree in science with botany and chemistry as major subject or in agricultural science or equivalent qualifications) to the Division of Plant Industry, Plant and Soils Laboratory, Brisbane, to undertake studies on the factors limiting legume establishment in sub-tropical areas and southern Queensland—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 4119 (February 14).

Rutherford Scholarship for research in any branch of the natural sciences—The Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1 (February 15).

University Demonstrator in Zoology—Dr. A. S. Watt, Department of Botany, Downing Street, Cambridge (February 15).

Senior Agricultural Economist, and an Assistant Agricultural Economist—The Registrar, King's College, Newcastle-upon-Tyne (February 16).

Senior Lecturer in Zoology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (February 28).

Physicist to Dundee Royal Infirmary, associated with a Lectureship in the Department of Physics in University College, Dundee—The Medical Superintendent, Royal Infirmary, Dundee (March 1).

Senior Lecturer in Mechanical Engineering at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (March 13).

Lecturer in Civil Engineering with particular interest in hydraulics—The Secretary, Queen's University, Belfast (March 15).

Senior Lecturer or Lecturer in Physics at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (March 15).

Carden Research Fellow (graduate in medicine, science or veterinary science) for research into the cause and cure of cancer, at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (March 31).

Associate Professor of Pathology and Associate Provincial Pathologist for the Province of Nova Scotia (combined position)—Dr. N. G. B. McLetchie, Provincial Pathologist, Dalhousie Medical School, Halifax, Nova Scotia, Canada.

Chief Scientific and Administrative Assistant (with a degree in botany or agriculture, or equivalent qualification) in the Official Seed Testing Station—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Superintendent in Charge of the Plant Engineering Division—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "Plant Engineering".

# MECHANISM OF GOVERNMENT IN A DEMOCRACY

THE proliferation of government and quasi-government activities, including problems inherent in nationalized industries, all compel attention to the question of the structure of government, centralization and accountability. Even if Mr. Harold Macmillan finds the measure of agreement which he stipulates as a condition for taking up the question of local government reform, he is likely to be confronted with problems of regional and central administration demanding clear thinking and prompt and firm decision, as is apparent, for example, from Mr. D. N. Chester's study of the financial and administrative relations of central and local government.

It is all to the good that fresh material for the public discussion of the wider and fundamental issues should continue to be forthcoming, if not by Government action, at least from impartial and authoritative sources. The survey of "British Government since 1918", which appeared two years ago, has been followed recently by a like survey limited to Parliament itself*; and, besides two recent broadcasts in which Mr. Christopher Hollis and Mr. John Strachey have discussed the position of parliament in relation to the party system and the survival of democracy, a recent book by Prof. G. W. Keeton, "The Passing of Parliament", has stated even more cogently the argument advanced three years earlier by Mr. Hollis in "Can Parliament Survive?". Fundamental issues in the functioning or survival of democratic institutions have been raised by discussions at the Present Question Conferences on "Freedom and Responsibility", "People at Work" and "Leadership in a Free Society", and also in studies like those on the nationalized industries by the Acton Society Trust, of Dr. Joseph Goldstein on the government of British trades unions, of Dr. W. H. Scott on industrial leadership and joint consultation, and of Mr. J. F. Scott and Mr. R. P. Lynton on management in its social context.

The position the Government has adopted in regard to the renewal of the Supplies and Services (Transitional Powers) Act, 1945, and the Expiry Laws Continuance Bill, makes consideration of the underlying issues a matter of urgency. The Home Secretary indicated on November 20 that the Government is very willing that an inquiry should be held into the procedures for exercising parliamentary control over delegated legislation. The inquiry, however, should be conducted by a more influential body than the Select Committee of the House of Commons suggested by Sir D. Maxwell Fyfe.

What is required is a thorough survey of the problem, comparable with that made twenty years ago by the Committee on Ministers' Powers under the chairmanship, first of Lord Donoughmore and then of Sir Leslie Scott. The multiplication of controls through war-time or security demands, as well as the increased responsibilities which the State has assumed by social legislation and economic stringency, makes it imperative to provide Parliament with some means of supervising really important emergency regulations more effectively than the power merely to accept or reject them outright. It is equally imperative to check any tendency for controls to proliferate.

---

* Parliament: a Survey. By Lord Campion, L. S. Amery, D. W. Brogan, J. J. Craik Henderson, Sir Arthur Salter, H. H. Dale, Ivor Thomas, F. W. Lascelles, H. O. S. Wade, Sir Cecil Carr, A. L. Goodhart, G. M. Young. Pp. 296. (London: George Allen and Unwin, Ltd., 1952.) 22s. 6d. net.

Credit should be given to the present Government for an attempt to classify and sift the regulations and powers it proposes to retain; but this is no substitute for the process of analysing those powers and defining their scope and purpose, and their relation to the part which the State should play in the society and economy which the Government in power envisages. The vigilance in regard to individual liberties and rights manifested in the debate in the House of Commons on November 20 may nevertheless induce the Government to look again at the whole problem before coming to the House another year and asking for renewal of these Acts. Mr. Boyd Carpenter gave specific assurances that the Government would not maintain greater powers than the existing situation demanded, and that the situation would be watched carefully to ensure that excessive powers were neither held nor sought.

The broad question of the safeguards required to reconcile individual freedom as well as the sovereignty of Parliament and the supremacy of the law with national security and the efficient discharge of the responsibilities of government is discussed impartially and at some length in "Parliament: a Survey", not merely by Sir Cecil Carr in his chapter on delegated legislation but also by Prof. E. C. S. Wade in a chapter on the courts and the constitution, and by Mr. G. M. Young in the concluding chapter on the future of parliamentary government. The difficulties are also noted by Mr. L. S. Amery in discussing the nature of British parliamentary government and by Mr. J. J. Craik Henderson in considering the dangers of a supreme parliament, as well as by Lord Campion, who contributes chapters on parliament and democracy and on parliamentary procedure. Although the protest may be less emphatic than those of Prof. G. W. Keeton or Mr. Hollis, it is no less firm; and in this book it has the further merit of being accompanied by constructive criticism.

Chiefly, such criticism comes from Mr. G. M. Young. Mr. Young sees no prospect of any change in the fundamental composition of the House of Commons, but leans to the idea of some collateral chamber, not exactly on the lines of the industrial parliament suggested by Mr. Hollis, and earlier still by Mr. Churchill in his Romanes Lecture of 1930 and by Mr. Harold Macmillan. He seems to have in mind a body in which group representation of such interests as the universities, local government authorities, and the like would provide the means for a regular and well-informed review of primary legislation and at the same time perhaps also a solution of the difficult problem of the relations between the national boards, [illegible], the trades unions and others. Besides this, he suggests that a committee on statutory instruments should be constituted, on similar lines to the Public Accounts Committee, with the duty of reviewing secondary legislation. Supplemented by regular, informal conferences between Ministers and their chief officials and interested groups in Parliament and the appointment of a Minister of State as 'general visitor' of the Civil Service, and assisted by a rotating team of experienced Civil servants, Mr. Young thinks we might well achieve a running audit of our administration and supply a steady wind of mutual intelligence and understanding, sufficient to keep the atmosphere clean and lively.

These interlocked proposals might well secure the essential conditions required to make the Select Committee Mr. Young proposes effective; but they promise little relief of Parliamentary time. That is a main problem, and while the contributors to this book in general fully recognize that an excessive burden is at present placed on Parliament—partly in consequence of legislative programmes in excess of the capacity alike of Parliament and the Civil Service—surprisingly little is said as to the possibility of devolution in some form or other, or of a vigorous reform of local government which might bring new life and efficiency to local institutions.

The view so strenuously urged by Mr. Hollis that we need to find a means of returning from the professional politician of to-day to conditions in which the average member of Parliament is able to take an active part in the life of the community, and is no longer called upon to sacrifice everything else to his Parliamentary duties, finds little support. Bagehot wrote in 1868: "The great defect of the House of Commons is that it has no leisure". We can scarcely hope to go back to a position in which Parliament only sits for a small part of the year—Burke's essential condition for Parliamentary government to be tolerable; but we must at least, if Parliament is to survive, provide the conditions in which a member of Parliament can respect Burke's great principle that he owes his electors not his industry only, but also his judgment, and that he betrays, instead of serving, them if he sacrifices it to their opinion.

Nevertheless, the contributors to this book agree with Mr. Hollis that the growth of party discipline is deadening and dangerous. The diminishing independence of members of Parliament may well tend to depreciate their quality; but the immediate issue is that, while there is general belief here and elsewhere in parliamentary traditions, Government powers can scarcely be curbed and controlled unless, as Prof. Wade rightly suggests, Government supporters themselves own a higher loyalty than party. Such opposition to Government action may demand a great sacrifice by a supporter of the party in power; but both Mr. Hollis and Mr. Strachey, in their broadcasts, were in agreement that on occasion such a revolt is both necessary and justifiable if democracy is to survive. It is, in fact, on such a spirit that the survival of Parliament and of democratic institutions depends. Devices for reducing the demands on Parliamentary time, for the devolution of functions to local, regional or even functional bodies, for the resolution of the problems of co-ordinating an increasing number of Ministries and Departments of State and for securing efficient public accounting and departmental efficiency, can only have their full effect when both Parliament and the Cabinet are inspired by a belief in democratic processes and respect Parliamentary tradition and procedure. Unless responsibility and power are thus allied, there are no effective safeguards, nor is it easy to see how even much more drastic constitutional changes than are here suggested could prove adequate. Ultimately, it depends on the extent to which not only Parliament but also the electorate generally understands what is involved, respects the democratic process and parliamentary procedure and is vigilant and resolute to act against any abuse, no matter what party considerations or private interest may require to be sacrificed.

In spite of its failure to relate, in any adequate sense, the functioning of Parliament itself with that of a virile system of local government, the book does bring out the dependence of Parliament on public understanding and support rather than on any system of checks and counter-checks. Less than justice is possibly also done to the need for wise and efficient central government, and no great contribution is made to the thinking out of how mutual intelligence can be made to permeate and ultimately to control the relations between Government and people. But on the price to be paid for the survival of Parliament, and of liberty as we understand it in a democratic State, there is a large measure of agreement, and that price is clearly indicated.

Mr. Craik Henderson insists, for example, that loyalty to something greater than party is the final safeguard against the abuse of executive or parliamentary supremacy. Prof. E. C. S. Wade sees in vigilant and enlightened criticism the only sure safeguard, outside the limited field controlled by the courts, against abuse of power by the executive, and Sir Cecil Carr calls for the "inbred insubordination" and "natural impulse" to resist authority with which Bagehot characterized the English people. Above all, the consistent protest against the abuse of party is accompanied by plain warning that there is no mechanical way of preserving democracy—the real dangers are within. No system of organization, however efficient, will preserve the form and spirit of democracy if there is lacking either vigilance or the will to act resolutely against abuse by those who reject the democratic tradition. If the pursuit of party policy is once placed above the sanctity of the democratic process of discussion, consultation and 'give and take', it is a short step to totalitarian tyranny.

These essays could contribute something to that vital task of education required for a clear understanding by the general body of the electorate of the nature and functioning of Parliamentary government in Britain and the conditions for its survival and success. They should also discourage efforts to make Parliamentary institutions more rigid, thus reducing the inherent flexibility which is part of their strength. At the same time, they help to bring home to every reader the need not only for vigilance against abuse but also for self-discipline, in order that the tradition and privilege of freedom may be preserved both in Parliament itself and in re-invigorated local government institutions. The reconciliation of power and responsibility is never finally achieved: it endures so long, and only so long, as the electorate is able and willing to discriminate between the true and the spurious, and is not deluded by whatever screen of propaganda may be spread by those who seek to pervert or destroy Parliamentary institutions.

# ANTOINE LAVOISIER

Antoine Lavoisier

Scientist, Economist, Social Reformer. By Dr. Douglas McKie. Pp. viii+335+18 plates. (London: Constable and Co., Ltd., 1952.) 30*s.* net.

LAVOISIER'S fame as "the founder of modern chemistry" has overshadowed his achievements as an administrator, a social reformer and an economist. These have had comparatively little attention, although his scientific work only took a fraction of his busy day, and from time to time he was occupied entirely with his other tasks.

Dr. Douglas McKie's earlier biography, published seventeen years ago, dealt mainly with Lavoisier's great reform of chemistry, comparable with the contribution of Newton to mechanics and astronomy and of Darwin to biology. Now the author has again earned our gratitude by this new life, with its comprehensive picture of Lavoisier's varied activities, which will be new to most readers. About a third of the book is devoted to Lavoisier's scientific work, and here Dr. McKie breaks little fresh ground. This must wait presumably for the publication of his laboratory notebooks.

When he turns to Lavoisier's record of public service, Dr. McKie's scholarly studies of French social history and politics in the eighteenth century give us an intimate picture of the background of Lavoisier's work. Lavoisier was only twenty-five when he "took the most fateful, and indeed ill-fated, step in his life" by joining the Tax-Farm, a financial corporation that leased from the Government the privilege of collecting the indirect taxes. He soon became one of its most efficient administrators and was constantly striving to remedy abuses and eliminate waste. His business journeys and his observant eye gave Lavoisier an unrivalled knowledge of social and economic conditions in France, and the statistics he collected through the officials of the Tax-Farm made possible his report on "The Territorial Wealth of France", which was a pioneer effort in national statistics giving for the first time an accurate estimate of the national income and its taxable limits. As the *Moniteur* said, "the work comprised in small compass the whole basis of political economy".

For seventeen years Lavoisier was one of the commissioners in charge of the production of gunpowder. He lived at the Arsenal, where again his organizing ability and his rapid drafting of reports and instructions were invaluable. Production was increased, great economies were made and the range of French weapons was increased by 60 per cent. He knew the miserable conditions of French agriculture, and in 1778 he bought an estate at Fréchines and started an experimental farm with the object of improving the most vital of all French industries. Dr. McKie describes the skill with which Lavoisier applied to farming the scientific analysis that marked all his researches and the great improvements in farming methods that he achieved.

When provincial assemblies were established in 1787, Lavoisier was elected a member of the assembly of Orléanais, and he was soon its outstanding figure. He saw so clearly the reforms that were long overdue: his memoranda on the *corvée*, on the state of agriculture, on old-age insurance, on savings banks and on the need for a geological survey show his modern outlook and his vision and imagination. Even in the dark days of the Revolution he never relaxed his efforts for France; in 1793 he presented a report to the National Convention on national education, envisaging the complete democratization of opportunity with free primary education for all children. He foresaw, too, the need for science and industry to work together. "Much that he urged in the organization and application of science has been realised only in our own time."

Dr. McKie tells the sad story of the final tragedy, adding fresh evidence about a packet of letters "written in English" which might have contributed to Lavoisier's death. This book gives an admirably balanced story of Lavoisier's many-sided life. It is written with fullness of knowledge, with great sympathy and understanding, and has the lucidity that characterised the writings of Lavoisier himself. It is clearly destined to be a standard history of Lavoisier's unique record of intellectual and practical achievement.

HAROLD HARTLEY

## BIRTH AND GROWTH OF EXPLOSIONS

### Initiation and Growth of Explosion in Liquids and Solids

By F. P. Bowden and A. D. Yoffe. (Cambridge Monographs on Physics.) Pp. xii+104+5 plates. (Cambridge: At the University Press, 1952.) 22*s*. 6*d*. net.

GREAT progress has been made during the past twenty years in the understanding of propagation of detonation in condensed explosives by the development of the hydrodynamic theory of detonation. This theory is purely mechanical, and like thermodynamics it has no curiosity, so that it tells us nothing about the nature of the decomposition or reaction of the explosive itself. It is all the more important, therefore, that collateral experimental work on the nature of the initiation and growth of explosion in condensed explosives should be prosecuted vigorously. Dr. F. P. Bowden and his school have carried out such work, first in Australia (with the then Commonwealth Council for Scientific and Industrial Research) during the Second World War and afterwards in Cambridge in the Research Laboratory on the Physics and Chemistry of Surfaces, and the results of the work are collected in the present monograph written by him in collaboration with Dr. A. D. Yoffe. Bowden's interest in explosives arose naturally from his work on the friction and lubrication of solids, which is described in a recent monograph written with Dr. D. Tabor as co-author (see *Nature*, **167**, 252; 1951). It was natural to utilize similar techniques for the study of the decomposition of explosives since these have always been tested by the now classical empirical tests involving impact and friction. Bowden and his school have, however, made a major advance in the understanding of the phenomena of the birth and growth of explosions in small quantities of material by demonstrating very elegantly that initiation is due to the formation of 'hot spots' of small but finite size in the explosive, and that such 'hot spots' are readily formed by adiabatic compression of minute gas-pockets trapped in the explosives. It is the essential simplicity of the disclosed mechanism which makes it such a valuable contribution.

The introductory chapter deals with the two principal theories of initiation of explosives by mechanical shock, namely, the tribochemical and thermal theories. As a result of their investigations, the authors favour the thermal theory and demonstrate that usually initiation is produced by the formation of a local 'hot spot'. Effective 'hot spots' can be produced in several ways; but the most important were found to be boundary friction between solid particles of high melting-point at points of rubbing contact, and adiabatic compression (and consequent heating) of minute gas or vapour bubbles in the explosive. The last chapter of the book deals with the growth and propagation of explosions from these minute 'hot spots'.

The book is illustrated with numerous photographs taken on rotating-drum cameras and showing the development of the explosion in various substances. In a considerable number of cases the 'hot spot' is succeeded by a phase of burning before detonation ensues, but in certain cases detonation ensues immediately after the 'hot spot'.

The book is readable and the arguments are readily followed; but it could have been more valuable to the specialist if more detailed and quantitative descriptions of the ingenious apparatus and methods used had been given. Nevertheless, the monograph is a very useful contribution to the literature and will be welcomed by both research workers and technicians in the explosives field.

JAMES TAYLOR

## HEALTH EDUCATION TO-DAY

### Health Education

A Guide to Principles and Practice. By Cyril Bibby. (Heinemann Education Series.) Pp. x+222. (London: William Heinemann, Ltd., 1951.) 17*s*. 6*d*. net.

WHAT should be expected of health education to-day? Many valuable and useful manuals of hygiene exist giving us the facts of health and health education; but a well-considered account of the judgment of the present-day experienced experts on the principles and practice of health education has been wanted for some time. In this book Mr. Cyril Bibby has now written such an account, and many will be most rewarded by a first perusal and subsequent constant reference. To-day we have reached that point in health education where our principles must be put into practice (even if improvisation is still often required through lack of funds or resources), otherwise the facts of health which we offer to individuals in the communities of to-day will fail to produce any lasting or worth-while effect. This is a particularly salient comment for the teachers of the young of all age-groups; for sister tutors in the training schools; for the teachers of future medical men and women; and especially for lecturers in health education in the training colleges for future teachers. Every individual passes through some teacher's hands at some time or other, and it is absolutely essential that all teachers, not just the scientific worker or the physical educationist, should know what part they can play towards inculcating habits, imparting information, fostering attitudes and responsibilities, and inspiring ideals for a balanced harmony in living. Thus the physical, mental, emotional and social aspects of health should be woven together for the individual within the community. To-day we are convinced that the immunization of babies and young children against diphtheria has reduced child mortality from diphtheria and lessened human suffering and sadness. Yet to-day there is a very great danger that parents are not going to practise the principle of diphtheria immunization for their children, because they do not appreciate the necessity for it or because they are apathetic. Hence the latest diphtheria poster "If——"; hence health education and its modern emphasis; hence the value of the book under review.

This book should be in the library of all teaching institutions—the training colleges for teachers and social workers, and the medical and nursing schools—because it is a book for educators, both lecturers and those students who are preparing themselves as widely as possible to be of use, example and inspiration to their future flocks. Some students and all teachers of health education should possess this book as a comprehensive reference book, while public libraries could well stock the book for members of the public and for those parents who will seek such information as it reliably gives.

Mr. Bibby has divided his book into two parts. The first part consists of eight readable chapters emphasizing sanely and in a manner fully approved by present-day pioneers what is really implied by health education to-day. It deals with aims, aspects, facts, media and with health education in the home, school, college and community. The second part consists of most valuable appendixes of schemes, curricula, syllabuses and programmes with a seasonable bias, together with a directory of health education organizations, useful statistics, recommendations for films, film strips, books and other media, all of which will be much appreciated by busy teachers and lecturers.

If we know whither we want to go, this excellent book will probably tell us the way from our present stage; if our aims are not really up to date, it will start us on the right road in health education.

P. M. TAYLOR

# BOTANY OF THE SCOTTISH HIGHLANDS

## Plant Life in the Scottish Highlands

Ecology and Adaptation to their Insect Visitors. By Alexander Edward Holden. Pp. xv+319+64 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1952.) 30*s*. net.

THOUGH the flora of the Scottish Highlands is comparatively poor as regards the number of species represented, this relative poverty is more than compensated by the interest and rarity of many plants which are not found elsewhere in Britain. The occurrence, distribution and affinities of the local species present some of the most fascinating problems connected with the British flora, and a systematic account of Highland botany dealing authoritatively with all aspects is long overdue.

The title and price of the work now under review suggest that this subject has at last been adequately treated. The book will certainly whet the appetite of field botanists, nowadays a vigorous and knowledgeable body in Britain, who at some time or other must visit the Highlands of Scotland if they wish to see species not occurring elsewhere. But, to students of the British flora, it will be a great disappointment, and particularly to those who have enjoyed memorable days plant-hunting in the Scottish mountains, and exciting hours afterwards in identifying their specimens. The professional botanist, and many amateurs also, will find little, if anything, original in the author's observations; but, on the other hand, will have much to criticize. The informed reader with a knowledge of plants and their ways will be rather chary of accepting the author's invitation early in the first chapter to regard plants "as sentient beings with hopes and fears and ambitions much like our own". This teleological theme is not a promising approach to the study of the vegetation of the Highlands, and it sets the tone of the whole work, which can scarcely be regarded as a serious contribution to the study of Scottish botany. It is quite clear that modern advances in the taxonomy of the British flora and the recent exciting discoveries of new plants in the Highlands have completely escaped the author's notice.

No attempt is made to give a scientific appreciation of the alpine and other habitats mentioned, and their plant communities, and the ecologists will have to look elsewhere for a critical appraisal of the physical conditions which influence plant life in the Highlands. The author deals with the vegetation in a most arbitrary way by selecting various habitats and describing rather cursorily one or two typical species.

The book will not greatly assist a beginner in the identification of plants, and it is necessary to point out that the nomenclature and taxonomy are often widely at variance with modern concepts. The serious divergences are too numerous to deal with in detail, and it is unfortunate that there are so many misleading statements that the author's generalizations must be read with caution. Nor are the distributional data always reliable, and one or two confident statements certainly need modification. It is no longer true that *Saxifraga cernua* is confined in Britain to the broken schist near the summit of Ben Lawers (p. 18); *Pinguicula alpina* (p. 194) has been extinct (since the beginning of the century) at its only certain Scottish station; and *Eriocaulon septangulare* (p. 222) is much more widely spread in Ireland than indicated, and the localization of the plant in Scotland is only partially correct.

A small chapter of four pages is considered sufficient to deal with the important aspects of distribution and affinities of the flora. As a result of this severe compression the picture of the sequence of geological events and climatic changes which have influenced the plant life of the Highlands is confused, and, in several respects, unsupported by scientific evidence.

It is a pity that this book cannot be recommended as an acceptable work on the vegetation of the Scottish Highlands. The typography is excellent and a wide selection of magnificent monochrome photographs by Mr. R. M. Adam illustrate many of the species and their habitats.

GEORGE TAYLOR

## A Textbook of Evolution

By Prof. Edward O. Dodson. Pp. xviii+419 (Philadelphia and London: W. B. Saunders Co., 1952.) 5 dollars; 25*s*.

THE past few decades have seen very noteworthy contributions to the study of evolution by such authors as Dobzhansky, Goldschmidt, Simpson, Mayr, Huxley, Haldane, Wright and others, but there are few text-books in which this modern work has been summarized in a form suitable for students in the first two years of their university career. This is the gap which E. O. Dodson has attempted to fill for American students, as G. S. Carter has for British. The book under notice is characterized by extreme clarity of exposition, both of the theoretical problems involved and of the factual material. It does perhaps attempt rather too much in some respects. Is it possible to summarize the whole comparative anatomy of the animal and plant kingdoms, from viruses up to the primates, in about 130 pages? Is it even necessary in a text-book devoted to evolution? British students of zoology, at any rate, will deal with such topics more fully in other parts of their course. The most valuable part of the book is the fourth, which is devoted to the recent studies on natural selection, species formation and similar evolutionary mechanisms. This contains a selection, on the whole judiciously made, of material which can otherwise only be found in original papers or books addressed to a much more advanced audience. The book is well illustrated and has a good index.

## Government Information and the Research Worker

Lectures delivered at a Vacation Course of the University of London School of Librarianship and Archives in April 1951. Edited with an Introduction by Ronald Staveley. Pp. vi+228. (London: Library Association, 1952.) 24*s*.; to members of the Association, 18*s*.

A PAPER by Mr. W. Cox on "H.M. Stationery Office Publications", given at the Aslib Conference in September 1949, provoked some discussion on Government publications. The subject was also raised at subsequent meetings of Aslib, both in Glasgow and in Manchester, in the following year, when difficulties being experienced in locating or obtaining such publications were stressed. In the following year a series of lectures, dealing with the resources of the major Government ministries and departments likely to be of value as sources of information to the research worker, were delivered at a vacation course of the University of London School of Librarianship and Archives. The interest taken in this course, which was attended by more than a hundred librarians and information officers, has now led the Library Association to publish these lectures, with the exception of two.

These exceptions, however, are important. The first was Mr. E. M. Nicholson's introductory address on "The Government and Research", and the second was that in which Dr. W. R. Francis described the present Government agencies and departments in which scientific research is undertaken or sponsored. These lectures are omitted at their authors' request because the subjects have since been covered in the official pamphlet "Government Scientific Organisation in the Civilian Field". Accordingly, the claims of the book on the interest of the scientist are slender, and are largely limited to Dr. D. J. Urquhart's brief chapter on the "Department of Scientific and Industrial Research as a Source of Information for Research Workers", and Mr. L. R. Poole's account of "The Technical Information and Documents Unit". The account of the research resources of the Ministry of Supply is also brief, due to the same security requirements which led to the omission of the three Service Ministries and the Ministry of Civil Aviation. This is not to say that the scientist or technologist will not find the accounts of some other departments, such as the Ministry of Fuel and Power or the Ministry of Works, of interest; but, by and large, the book is mainly of interest to the social scientist rather than to the scientist in general.

Subject to the omissions mentioned above the book covers the ground fairly thoroughly, and the various chapters bring out the extent to which the needs of both librarian and research worker are appreciated at a high level in most ministries, and the extent to which the departments are anxious to be of service.

R. B.

## Avicenna, Scientist and Philosopher

A Millenary Symposium. Edited by G. M. Wickens. Pp. 128. (London: Luzac and Co., Ltd., 1952.) 15*s*.

IN the year A.D. 980 was born within the borders of Afghanistan one who came to be nicknamed Ibn Sina. During the fifty-seven years of his life he became a figure of world renown in the person whom the medieval schoolmen called Avicenna. A Persian of the Persians, he was an intellectual prodigy, poet, mystic, medical man and *bon viveur* all rolled into one. Alas, he was not devoid of conceit, combined with a curiously refined arrogance. His influence through the ages has been tremendous, as this collection of lectures delivered at Cambridge in his honour abundantly proves. The six speakers comprised two Arabists, two Hebraists, a scientist-philosopher, and a modern linguist—surely an appropriate team.

By them we are given an insight into Avicenna's life and work; an estimate of his place in Asiatic philosophy; an account of some aspects of his activities; an appraisal of his influence upon Jewish thought, and upon medieval scientific tradition; and finally, a description of the effect he had upon the thirteenth century, more especially, of course, upon St. Thomas Aquinas. Compact references accompany the text.

Avicenna, who contributed to metaphysics the concept of a necessary Being whose essence and existence were identical, was the same person who experimented with many drugs, and demonstrated his mastery of the inductive method. Authors and publishers have done well to pay him homage in producing this first-class book.

F. I. G. Rawlins

## Green Thoughts

By Sir Stephen Tallents. Pp. 192. (London: Faber and Faber, Ltd., 1952.) 15*s*. net.

THOSE who enjoy Sir Stephen Tallents's essays in periodicals and newspapers will be delighted to have this collection in more permanent form.

The anthology covers a wide range of country topics and pursuits around the year, and they are described with characteristic charm. One feels throughout that Sir Stephen's affection for his wood-fed fire, his crooked rake and beloved scythe, are part of the heritage of the venerable sanctuary which is now his home. The chapters on moles and nettles are particularly rewarding; but the final essay on scything is surely the most complete memoir of the art and theory of that ancient practice.

# ACCELERATION OF HEAVY IONS TO HIGH ENERGIES

By Dr. D. WALKER and Dr. J. H. FREMLIN

Physics Department, University of Birmingham

SINCE the first development of the cyclotron by Lawrence and Livingston in 1931, relatively little attention has been paid to the acceleration by its means of ions heavier than $^4$He. It was natural enough in the development of nuclear physics that attention should first have been given to the information which could be obtained by the bombardment of nuclei with the simplest possible particles; and rightly, the emphasis is still the same to-day. However, the study of fast heavy ions is of interest on its own account. Such ions occur in nuclear disintegration and recoil processes, and in the fission of heavy elements. Interest in them was stimulated by the discovery of nuclei of medium atomic number in the primary cosmic radiation by Freier *et al.*[1] in 1948. As bombarding particles for producing nuclear transformations, heavy ions accelerated in a cyclotron may prove of value in particular problems as, for example, the production of transuranic elements[2,3]. Here the product nucleus desired might differ greatly in mass and charge from the available target nucleus. Recently, Breit *et al.*[4] have pointed out that it might be possible to obtain specific information on nuclear structure, which cannot readily be obtained otherwise, by bombarding nuclei with energetic heavy ions.

## Technical Considerations

Three main differences may be noted when we compare the acceleration of heavy ions in a cyclotron with the acceleration of hydrogen or helium ions.

First, since the binding energy of the $K$-electrons in an atom varies as the square of the atomic number, it becomes increasingly difficult with the heavier atoms to produce high states of ionization directly in, or near, the ion source of the cyclotron. Indeed, this effect is already apparent if we compare hydrogen and helium, since it is well known that the beams of doubly-charged helium which can be obtained in a cyclotron are less than the corresponding beams of singly-charged deuterium. Now we are interested in producing highly-charged ions because the energy which can be imparted to an ion of a particular mass, using a given cyclotron magnet, increases with the ionic charge. This follows from the relation $p = Ber$, in which $p$ is the momentum of an ion of charge $e$ at a radius $r$ where the magnetic induction is $B$. With highly-charged ions it is possible, in a fixed-frequency cyclotron 60 in. in diameter, to produce ions energetic enough to penetrate the Coulomb barrier of even the heaviest nuclei. The Birmingham cyclotron of this diameter can produce ions with energies of about 10 $A$ MeV., where $A$ is the atomic mass number.

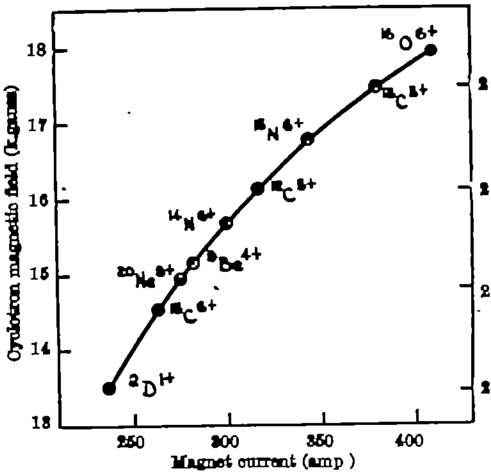
Secondly, the mass-to-charge ratios of ions of stable isotopes heavier than helium-3 are all greater than that of the deuteron (except for fully stripped nuclei which contain equal numbers of protons and neutrons). The angular frequency ($\omega$) of an ion in a cyclotron is given by $\omega = B(e/m_0)(1 + E/m_0c^2)^{-1}$, where $m_0$ is the rest mass of the ion and $E$ its kinetic energy. Consequently all the heavier ions, with the exceptions noted, have a larger ratio ($B/\omega$) for the same $E/m_0c^2$ than does the deuteron. For resonance with a given cyclotron radio-frequency, $B$ may be much larger than that required for the deuteron, as can be seen from the accompanying graph.

Thirdly, not all elements heavier than helium can be obtained in gaseous compounds suitable for the conventional gas-discharge ion-source used in cyclotrons. Thus in some cases, as for example beryllium-9, solid sources of ions must be used.

## Work in the United States on the Acceleration of Heavy Ions

The pioneering work on the acceleration of ions heavier than $^4$He, as in so many other branches of cyclotron technique, was carried out at the Radiation Laboratory of the University of California at Berkeley. The first work was reported in a brief abstract by Alvarez[5] in 1940. He used the fixed-frequency cyclotron of 37 in. diameter, the cyclotron chamber being filled with methane. A beam of $^{12}C^{6+}$ ions of about 50 MeV. was detected by means of a proportional counter and linear amplifier. Since the resonances of $^{12}C^{6+}$ and $^4He^{2+}$ ions lie close together (the mass-to-charge ratios of $^{12}C^{6+}$ and $^4He^{2+}$ differ by only one part in 1,500), care had to be taken to resolve the $^{12}C^{6+}$ beam in the presence of the helium contamination of the cyclotron. To do this clearly, it was necessary to operate with the cyclotron magnetic field below the optimum value for the acceleration of $^{12}C^{6+}$, and this led to a weak beam of only about 500 carbon ions per minute. Further work with the Berkeley 60-in. cyclotron, reported briefly by Condit[6] and by York *et al.*[7], led up to the work of Miller *et al.*[8] with the same machine. The last-named authors used a hooded capillary ion-source fed with carbon dioxide gas. They obtained external beams of $10^5$ ions per sec. of $^{12}C^{6+}$ at 115 MeV. and, using carbon dioxide enriched to 50 per cent carbon-13, of $10^4$ ions per sec. of $^{13}C^{6+}$ at 122 MeV. They estimated an internal beam of $^{12}C^{6+}$ of about $10^8$ ions per sec.

Recently, Chou *et al.*[9], using the Chicago synchrocyclotron, have accelerated carbon ions to energies as high as 1,100 MeV. They mention the acceleration



Magnetic field plotted against magnet current for the Birmingham cyclotron. Heavy-ion resonances are observed to occur at the magnet currents indicated. For the cyclotron frequency of 10·31 Mc./sec., the ionic mass-to-charge ratios calculated to give resonance with the magnetic field are shown on the right-hand scale. Mass-to-charge ratios are expressed as (atomic mass) ÷ (number of electron charges) of $^{12}C^{5+}$ ions as well as completely stripped carbon ions. Carbon dioxide gas was used in the ion-source. They have also accelerated $^{9}Be^{4+}$ ions, and assumed in this case that the beryllium ions were evaporated from an internal target which is normally subjected to intense proton bombardment when the cyclotron is accelerating protons. The authors do not mention the strengths of beam obtained, but these are apparently at least adequate for the bombardment of photographic emulsions.

## Work at Birmingham on the Acceleration of Heavy Ions

In the Nuffield Laboratory at the University of Birmingham, using the 60-in. fixed-frequency cyclotron, we have recently made a study of heavy ion resonances over a wide range of magnetic fields. Resonances due to the following ions, listed in order of increasing mass-to-charge ratio, have been studied: $^{12}C^{6+}$, $^{20}Ne^{9+}$, $^{9}Be^{4+}$, $^{14}N^{6+}$, $^{12}C^{5+}$, $^{15}N^{6+}$, $^{13}C^{5+}$ and $^{16}O^{6+}$. A scintillating crystal (potassium iodide activated with thallium[7], mounted on a 'Perspex' light guide and inserted between the 'dees' at radii varying from 24 to 27½ in., was used to detect the resonant beams of ions. The crystal was covered with 17 microns of aluminium. At a radius of 27 in. the kinetic energy of an ion, revolving about the centre of the cyclotron with a frequency equal to that of the radio-frequency accelerating voltage (10·31 Mc./sec.), is approximately 10 *A* MeV., where *A* is the atomic mass number of the ion. This maximum attainable energy therefore varies from 90 MeV. for beryllium-9 to 200 MeV. for neon-20. For producing carbon ions, the ion-source was fed with carbon dioxide gas, while the source of nitrogen ions so far has simply been the residual air in the cyclotron tank. To locate the $^{20}Ne^{9+}$ resonance, the ion-source was fed with neon gas. In order to accelerate $^{9}Be^{4+}$, the normal molybdenum tip of the ion-source was replaced by one of beryllium metal, and during some of the runs with the beryllium tip the ion-source was fed with hydrogen gas instead of carbon dioxide. When the cyclotron was running, this beryllium metal tip became heated to a bright red.

The mean magnetic field in the cyclotron is plotted against the current in the magnet coils in the accompanying graph. Superimposed on this curve, at the observed magnet currents, are the resonances due to the various ions. (The $^{2}D^{1+}$ resonance, determined by other means, is included for comparison.) These resonances correspond exactly, for the cyclotron frequency of 10·31 Mc./sec., to the mass-to-charge ratios indicated on the right-hand scale. This provides unequivocal identification of the resonances. The method has not been used to study resonances of ions for which mass-to-charge ratios are close to those of $^{2}D^{1+}$ and $^{4}He^{2+}$, for fear of damaging the crystal with intense beams of the latter ions arising from contamination of the cyclotron. It has in any event been considered an advantage to work with heavy ions the resonances of which are widely separated from those of $^{2}D^{1+}$ and $^{4}He^{2+}$. This eliminates the possibility of experiments, using the heavy ion beams, becoming complicated by the possible presence of $^{2}D^{1+}$ and $^{4}He^{2+}$ ions.

A striking feature noticed was the great prominence of the $^{12}C^{6+}$, $^{14}N^{6+}$, $^{15}N^{6+}$ and $^{16}O^{6+}$ resonances. The $^{13}C^{5+}$ resonance is much weaker than the $^{12}C^{6+}$ resonance, while $^{15}N^{7+}$ and $^{16}O^{7+}$ are not observed at all. It is to be noted that, when the cyclotron is adjusted to accelerate six-charged ions, doubly-charged ions of the same species have a frequency of revolution in the cyclotron which, in the approximation $E \ll m_0c^2$, is one-third of the cyclotron radio-frequency. Doubly-charged ions can thus be accelerated, and at a given radius will have an energy which is one-ninth of that of a six-charged ion if both ions are revolving about the centre of the cyclotron. There can be no doubt that pre-acceleration of the ions in the doubly-charged state (third harmonic acceleration) aids in an important manner in the ultimate stripping of the ions to the six-charged state through collisions with residual gas molecules. Fifth and seventh harmonic acceleration are increasingly less effective for this purpose. Of the still heavier neon ions, only the $^{20}Ne^{9+}$ ion, which fulfils the third harmonic condition, has been so far studied. The use of a scintillating crystal for the detection of the resonant beams makes possible a study of the structure of the resonance curves (the variation of counting-rate with magnetic field), and of the energy distribution of the ions by pulse-height analysis. Evidence from these studies lends support to the theory of third harmonic pre-acceleration. It is intended to publish elsewhere a more detailed account of this study of acceleration mechanisms. Condit[8] and Miller[9] have mentioned that harmonic acceleration can take place with carbon ions, but there appears to be no mention in the published literature of its possible importance for subsequent electron stripping.

In the case of $^{9}Be^{4+}$, odd harmonic pre-acceleration is not possible. However, it is felt that, owing to the comparatively low atomic number of beryllium, it is relatively easy to get the atoms fully stripped without recourse to harmonic pre-acceleration. The observed fact is certainly that beams of $^{9}Be^{4+}$ can be readily obtained which are at least as good as the beams of $^{12}C^{6+}$ obtained when carbon dioxide of normal isotopic constitution is used in the ion-source.

The Birmingham work has not so far explored the upper limits of beam-strengths obtainable. On strong resonances it is easily possible to saturate the counting system with counting-rates in excess of $10^4$ per sec. At this stage we must take the work of Miller *et al.*[9], mentioned above, as an indication of beam-strengths which have been obtained in a similar cyclotron. The beam-strengths used at Birmingham so far are more than adequate for bombarding photographic emulsions internally in the cyclotron. In the case of $^{9}Be^{4+}$, bombardment of emulsions has also been carried out with a deflected external beam. In this connexion it is worth noting that, with increasing mass-to-charge ratio, higher deflecting voltages are required to produce external beams.

Harmonic pre-acceleration might well be important in helping to obtain large beams of heavy ions. An alternative scheme, for injecting heavy ions into a synchrocyclotron or a heavy-particle synchrotron, has been put forward by Tobias[10]. A linear accelerator would pre-accelerate ions carrying a low charge. These ions would be injected into the synchrocyclotron or synchrotron, tangentially to a desired orbit, and would be fully stripped at the orbit by passing them through a thin foil.

## Experimental Studies with Heavy Ion Beams

The study of a number of problems has been made possible by the successful acceleration of heavy ions, and exploratory work on some of these problems has been reported.

Miller *et al.*[2] have reported observing the nuclear reactions $^{27}$Al($^{12}$C,$\alpha n$)$^{34}$Cl and $^{197}$Au($^{12}$C,$4n$)$^{205}$At with 115-MeV. $^{12}$C$^{6+}$ ions. The possible value of such reactions in the production of transuranic elements, where a large change of nuclear charge and mass is required when bombarding an available isotope, is obvious. Ghiorso *et al.*[3], using 120-MeV. $^{12}$C$^{6+}$ ions, have obtained small yields of californium-244 from the reaction $^{238}$U($^{12}$C,$6n$)$^{244}$Cf and report also that californium-246 is probably obtained by the reaction $^{238}$U($^{12}$C,$4n$)$^{246}$Cf with a comparable cross-section.

Miller[9] has reported a preliminary study of the nuclear interactions of 120-MeV. $^{12}$C ions and 130-MeV. $^{13}$C ions in photographic emulsions. External beams of $^{12}$C$^{6+}$ and $^{13}$C$^{6+}$ ions from the Berkeley 60-in. cyclotron were used. In exposing the emulsions, a slit system was used to eliminate contaminating particles. Using for the purpose of the calculation the full lengths of the carbon tracks in the emulsion, he finds the cross-section for inelastic nuclear events in which charged particles are emitted to be (0·40 ± 0·03) barn for $^{12}$C and (0·37 ± 0·03) barn for $^{13}$C. A feature of the nuclear explosions (stars) is the large number of α-particles emerging. The maximum number of prongs observed in a star was seven. A photograph of this star appears with his communication. It was caused by a carbon nucleus slowed down in the emulsion to 90 MeV. We have also observed, at Birmingham, stars produced in photographic emulsions by $^{9}$Be, $^{12}$C and other ions.

Giles and Barkas[11] have reported a preliminary study of the pick-up of electrons by $^{12}$C ions as they slow down in photographic emulsions. This study was carried out by counting the varying number of gaps in the tracks recorded in Ilford *D*-1 emulsions. The number of gaps is related inversely to the ionization density, which in turn is related to the mean charge carried by the ion. Such investigations should provide a check on the theories[12-15] which relate the mean charge carried by an ion passing through matter to the velocity of the ion. These theories were developed originally in a study of the range–energy relations of fission fragments and recoil nuclei. Our work in Birmingham has shown clearly the difference in appearance of tracks in photographic emulsions due to such ions as $^{4}$He, $^{9}$Be, $^{12}$C and $^{20}$Ne, which are well spaced in atomic number.

Chou *et al.*[8] have studied the density of δ-rays (recoil electrons) along the tracks of energetic carbon and beryllium ions in photographic emulsions. They find agreement with the theory of Mott[16]. This theory was first applied to the tracks of heavy ions of the primary cosmic radiation by Bradt and Peters[17]. To identify the heavy ions, these authors used the fact that the number of δ-rays with energies in a given interval is, in a certain approximation, proportional to $Z^2/\beta^2$, where $Z$ is the charge carried by the ion and β its velocity. Chou *et al.*[8] have also studied the multiple scattering of carbon ions at energies up to 1,100 MeV. by the method of Fowler[18] and find agreement with theory[19]. They have also published a photograph of a star, initiated in a photographic emulsion by a 750-MeV. carbon nucleus, in which nine charged particles were emitted.

Breit *et al.*[4], in a theoretical paper, have considered in some detail the nuclear effects which might be expected in bombardments by ions such as $^{12}$C and $^{16}$O, and have estimated the distortion effects produced in target nuclei by the incident ions. This distortion might be expected to affect the thresholds of reactions which are determined by Coulomb barriers, and also the relative probabilities of emission of the various reaction products which might be observed. One might also expect effects due to the leakage of protons and neutrons out of the two colliding heavy nuclei by wave-mechanical penetration of the regions of negative kinetic energy between the nuclei. If practicable, exploration of the latter effect would amount to a study of the halo of neutrons and protons surrounding the more compact nuclear interior. It might be helpful in determining the number of particles at the nuclear surface having a given energy.

We should like particularly to acknowledge the help of Dr. W. I. B. Smith and Mr. W. Hardy in the work carried out with the Birmingham cyclotron. We are also indebted to Mr. W. T. Link for experimental assistance, and to Profs. P. B. Moon and W. E. Burcham for their interest.

# POLYPLOIDY IN ANIMALS

By Dr. C. D. DARLINGTON, F.R.S.
John Innes Horticultural Institution, Bayfordbury, Hertford

## Origins of Polyploidy

IN all cellular organisms, so far as we know, errors in cell division can give rise to cells, tissues and individuals with a multiplied or polyploid chromosome number. Animals and plants have, in general, proved capable of adjusting themselves successfully to a wide range of numbers. In plants not only are nuclei and cells increased in size when the chromosome number is doubled but the individual also. The series haploid–diploid–triploid usually gives a steady, if not a proportionate increase in size of the whole plant, and this may even continue to the tetraploid and beyond. Such an increase is found, of course, only with a genetically uniform chromosome set, without mutations or selection. For if the increase in size is at all disadvantageous to a polyploid race of plants in Nature, selection in later generations can readily reduce it again, and evidently often has done so.

In some animals these rules still apply. In triploid *Drosophila*, nuclei and cells, organs and individuals are all larger than in the diploid. But in Amphibia, although the nuclei and cells may be proportionately larger, the individuals are scarcely increased in size at all. The larger animals, which most need to do so, regulate their size, subordinating the cell to the individual, to a degree unknown in the plant[1]. For this reason we find in animals mosaics, and even regulated combinations of diploid and polyploid tissues as successful and important as are the chimæras in plants.

There is thus no physiological difficulty about the origin of new polyploid races in either plants or animals. For both, the difficulties lie in the mechanism of meiosis, and its consequences in germ cell formation. The situation is best known in plants. A tetraploid derived from a true breeding diploid has four identical sets of chromosomes which form groups of four at meiosis. These segregate irregularly, three-to-one as well as two-to-two, and the result is the formation of unbalanced and partly inviable progeny, in other words, infertility. Only when a sterile diploid, a hybrid with two dissimilar sets of chromosomes, *AA′*, *BB′* and so on, doubles its number, do the chromosomes regularly associate in pairs *A*—*A*, *A′*—*A′* and so on, in the tetraploid. Doubling in a hybrid diploid thus restores fertility, instead of impairing it: it gives us a pure-breeding hybrid tetraploid which behaves like an ordinary diploid. New polyploid species of plants are continually arising in this way, *Raphano-Brassica* in experiment and *Spartina townsendii* in Nature, *Triticale* in agriculture and *Aesculus carnea* in the garden[2].

## Obstacles to Polyploidy

When abundant polyploids had been found in plants, the question arose of why polyploidy was rarer in animals than in plants. Muller, broaching this question, suggested that an obstacle lay in the disturbance to be expected in the sex-determination of bisexual animals[3]. Disturbance might arise, in the first place, from the failure of the pairing and segregation of *X* and *Y* chromosomes. Also, in the second place, it might arise from the unsuitable balance between the sex chromosomes and the three or four sets of autosomes. New types of balance lead to sterility of the heterozygous sex in *Drosophila* and they might be expected to do so elsewhere.

Later knowledge has largely borne out Muller's expectation. Polyploidy is infrequent in bisexual, although it is probably not infrequent in hermaphrodite, animals; and it is certainly widespread wherever parthenogenesis has been superimposed on a bisexual system. This has happened in nearly all those groups of invertebrates, the most recent being the earthworms, where the question has been studied[4]. In animals as in plants it is indeed by polyploidy that we can trace the evolutionary sequence. We can say that triploidy determined the origin of a parthenogenetic race or species, since the fertilization of a diploid egg by a haploid sperm or pollen nucleus was the first as well as the last genetic event in its history[5].

The breeding of polyploid salamanders also partly bears out Muller's view. Humphrey and Fankhauser have succeeded in raising four generations of polyploids; but they have done so only by crossing polyploid females with diploid males[6]. We have to notice, however, that it is the males, the homozygous sex in this group, which are sterile as tetraploids. How are we to account for this?

Hitherto, hybrids and polyploids have been almost too easy to make in the newts and salamanders. For the analysis of fertility, however, in their polyploid forms we need studies of the same character as those in polyploid plants. We need a comparison of fertilities of diploids and polyploids in pure forms and in hybrids; and they must be precisely first crosses and not later derivatives. These results must be compared with chromosome behaviour at meiosis at least in the male.

So far as we can tell, then, we may say that the sterility of the salamanders seems to be as much that of the non-hybrid tetraploid known in the plant as of the sexually unbalanced type expected in the animal. The limited fertility of the females may itself be helped in these salamanders by a hybrid origin.

## Sex-determining Systems

Sex determination may not, therefore, offer the obstacle to polyploidy in animals that we had thought. Nor, indeed, from what we now know of sex determination in animals does it seem likely that the balance system of determination known in *Drosophila* is universal. Rather it is at the end of an evolutionary sequence which arises from what Muller has described as a mere trigger mechanism[3]. For example, the classical animal of the cytologist, *Ascaris megalocephala*, which begins from a basic chromosome number of one, exists in diploid and tetraploid races in Europe and America. These may well be mutually convertible, and they certainly have given rise to hexaploid and octoploid forms which, I understand from Prof. Goldschmidt, exist as races infesting the horses of Mongolia. Since *Ascaris* is differentiated into male and female animals, the differentiation in these polyploids must depend on a trigger rather than a balance.

In the Amphibia such a rudimentary trigger system of sex-determination seems to be general. No differentiated sex chromosomes are to be seen; and in different groups, even in related species, the homozygous–heterozygous relationship may be reversed as between the two sexes, just as it has been in the separate evolution of birds and mammals.

Instability is now seen to be characteristic of many sex-determining mechanisms. The evidence in the mammals is both cytological and genetical. Chains of three sex chromosomes in the marsupial *Potorous tridactylus*[7], and giant sex chromosomes in the vole *Microtus agrestis*[8], both indicate an incorporation of autosomes in the segregating system which determines sex. This means elaboration. The opposite process of degradation, the replacement of a balance by a trigger, is more difficult. For this a new sex-determining segregation must be set up as a single gene-difference between a pair of *X*'s or a pair of autosomes.

A model of such a transformation has indeed been described in man himself (as also, indeed, in *Drosophila*). The Pettersson–Bonnier gene in the *X* chromosome of man converts an *X Y* individual into an apparent or spurious woman[9]. The model is imperfect, since the result is sterile and it arises in the heterozygous sex, merely producing a redundant heterozygosity. But it shows how a new trigger could be brought into action even in our own species.

It is, indeed, above all in the mammals, with their highly developed endocrine systems, that the trigger mechanism may fail to develop into a full balance of the kind realized in *Drosophila*. In this case an obstacle to polyploidy would be removed. Both triploids and tetraploids of the heterozygous sex might be fertile, as they are in the salamander.

Where sex chromosomes are differentiated as in the mammals, another possible difficulty is removed. The sex chromosomes pair only in their short pairing segments and rarely, therefore, form more than one chiasma. For them, therefore, multiple associations are more difficult than for the autosomes. In a tetraploid mammal, association at meiosis will be more regularly in pairs for the $X$ and $Y$ chromosomes than for the autosomes. This regularity will be increased, as in polyploid plants, by any hybridity of the diploid or tetraploid from which a new type arises. There will be $X$—$Y$ and $X'$—$Y'$ pairs in the heterozygous sex from which all the usual combinations can be derived.

## Polyploid Mammals

The sex-determining mechanism does not, therefore, exclude the possibility of tetraploidy in the mammals, especially tetraploidy arising from hybridization. In this regard certain new observations are of great interest. Fischberg and Beatty have found polyploids, including both triploids and tetraploids, among embryos of the mouse. They are more frequent after crossing, rising to more than 3 per cent spontaneously[10]; and they can be induced by heat treatment of the egg before implantation in as many as 20 per cent[11]. Do such embryos ever reach maturity?

For evidence we must turn to observations of chromosome numbers in wild species of mammals. Here we are faced with a different kind of problem. In all groups of vertebrates there have been doubtful indications of polyploid species. They have been doubtful owing to the sporadic distribution of chromosome studies and the uncertainty of the results. Our present knowledge of the vertebrates, it must be understood, corresponds in proportion and precision with what was known of the flowering plants thirty years ago. After that time a rapid improvement took place in plant technique which changed the face of the subject: the new treatments were easier and their results were more accurate.

The same advance is now taking place in the study of vertebrate chromosomes. Only a few years have passed since La Cour, in showing the part played by nucleic acid supply in the normal and abnormal differentiation of blood precursors in man, displayed the chromosome complement satisfactorily for the first time[12]. Now, from tissue cultures of the human embryo, Hsu has been able to obtain pictures of the chromosome complement such as have rarely been seen in the past outside the flowering plants[13].

The first important result of the new methods has been to show that polyploid species of mammals exist; the second to suggest that they are of hybrid origin. For some time chromosome numbers of 22 and 44 have been claimed for species of hamster. But the possibility of polyploidy has been mentioned by Matthey only to be rejected (doubtless for the theoretical reasons we have been discussing)[14]. Sachs, after confirming the simple doubling of number, has now given the evidence in full. He has shown that form, distribution and history all support the assumption of a recent tetraploid origin for the golden hamster. They indicate its origin as a hybrid in the Caucasian region, where two geologically older species, its presumed parents, overlap[6].

The evolution of the hamsters may be represented as follows:

*Cricetus cricetus* × *Cricetulus griseus*
(Europe eastwards) (China westwards)
22 chromosomes 22 chromosomes

*Mesocricetus auratus*
Syrian or golden hamster
44 chromosomes

Here we see the genesis and history of a species diagrammatically revealed, much as it was revealed twenty-five years ago in the now classical instances of polyploid plants of recent origin.

We can seldom expect to find the records so neatly preserved. Species often die, and chromosomes are often broken. What we shall usually find is the bald fact of an approximate two-to-one ratio of chromosome numbers. Such a ratio seems to connect the only two of the innumerable races of African and Indian gerbils which have so far been described, both of them this year[6,15]:

*Tatera brantsii draco* : $2n = 34$ (Tobias)
*Tatera indica ceylonica* : $2n = 72$ (Sachs)

How could a polyploid species arise in the way the golden hamster seems to have done? It might come about, as it commonly does in plants, through the frequent production of infertile diploid hybrids whose sole means of making effective germ cells would be through non-reduction, the failure of the first or second meiotic division. The eggs would then all have $XX$ chromosomes, the sperm $XX$, $XY$ and $YY$. If the last of these gave less fertile zygotes, the others, $XXXX$ and $XXXY$, might well be efficient enough to start a new species with sexes in equal numbers.

An alternative possibility is favoured by the mouse experiments. It is that the new tetraploids arose at fertilization in the original crossing of the two species through non-reduction in both parental species. There are, however, as the salamander experiments have shown, only too many possibilities for the origin and breeding of polyploids. When we recall that the chromosome numbers are accurately known for much less than one per cent of all the species of mammals, it becomes clear that polyploidy may have been concerned closely or remotely in the history of any or all mammalian groups.

## Origin of Man

Now, among the orders of mammals, the primates are almost the least explored in their chromosome history. At the present moment the chromosome number is known only for one or two species of monkeys apart from ourselves: and those observations, although no doubt accurate, were made nearly thirty years ago[16,17]. Where cytologists abound it seems that monkeys are scarce. Moreover, the owners of collections of living animals maintained for exhibition to the public, or for scientific purposes, are not disposed to lend their precious charges for investigation; or, at least, not until the animals are dead and their chromosomes no longer decipherable. It might well happen therefore that, after the last gorillas, chimpanzees and orang-utans had all expired in their cages, we still should not know their chromosome numbers. We should not know whether, for example, one or more of them had had half or twice our own outfit of chromosomes. Or whether we had differed only by a small amount of fragmentation and the loss or gain of a few inconvenient genes.

Great institutions have been devoted to collecting and preserving, describing and naming, the bony fragments of our ancestors and relatives, and great bodies of literature have been brought forth by their labours. Rightly so. Yet at the cost of a few hundred cells, a few drops of blood, a few moments of discomfort to the animals, and a few hours of work to a cytologist, the genetic record of human evolution could be laid bare. It would, perhaps, be worth while.

# THE LOGIC OF EXPERIMENT

By Dr. J. BRONOWSKI
Central Research Establishment, National Coal Board

EVERYTHING in our experience is particular; and science seeks to link it by general laws. How does the observer pass from the particular phenomena to the laws for which they are thought to provide evidence? This is the classical problem of induction, as a human habit. We are here concerned, however, only with that part of it which is formalized in scientific method.

A law, in this meaning, is a statement from which phenomena can be derived by deductive steps. The aim of induction in science is therefore to propose a system of laws from which everything in our experience will be seen to follow by strict deduction.

## The Axiomatic Model

Ideally, such a system is put in an axiomatic form. That is, there is postulated a set of primitive entities, of whatever kind—they may be reflexes, or genes, or enzymes, or mass and force (for they need not be observable). A system of axioms then lays down how these entities behave and may be combined; Mendel's rules or Newton's laws of motion are examples. With this goes a dictionary to say what conjunctions of the fundamental entities can be observed, and what these observable appearances are. The model is now ready to be set going.

The model proceeds by steps, and in a natural science these steps take place in time. Some of the axioms therefore must say how the postulated entities move or change in time. These are, broadly, the causal laws, which describe sequence or consequence.

## Experiments in Time

There can, of course, be no assurance that these sequences will follow in the future the same laws that they have followed in the past. Nature might at any instant break with herself. This remark is a valid warning against prediction and other extrapolations; but it does not, as has been thought, bear upon the process of induction which underlies them. Induction remains the process by which science seeks to trace an order in what has been experienced. At any instant (even at the instant after an experiment) this search can involve only the past record.

When an experiment repeats what was done before, it adds to this record. It does so, first, to give a narrower estimate of error. But even if experiments were free from error, the repetition would not be trivial. For it serves to scrutinize, from time to time, the way in which time has been written into the axioms. For example, we go on measuring the speed of light for both reasons, for we are by no means sure that it is not growing with time.

## 'Probability' of Laws

To assert that a law is true is to claim that, ideally, all the phenomena which can be deduced from it could be verified. Even when we confine ourselves to the past record, this is a claim that cannot be proved; it can at best be tested. For any record can only be a sample, even of the history which it records: it is the nature of experience that it only samples the universe. It is therefore pertinent to ask of a law or model: How probable is it that the configurations which it generates would have matched the universe at all points, because they match it at so many sample points?

The question is commonly put in this form; but it is not happy, for the phrase 'how probable' cannot make sense. The probability of hypotheses is a pointless inquiry. There is always an infinity of distributions from which the finite set of sample points might have been drawn; and there can always be constructed an infinity of hypotheses or models which will generate the same finite record. In any absolute sense, the probability that one hypothesis is right is therefore always zero.

This difficulty is not met by making the sample larger. Experiments are, of course, designed (this is their third function) to test the fit of the axiomatic model at new sample points. If they fail, the model is rejected; but their success, even when it is as spectacular as the discovery of Neptune, can never make the model probable in itself. It can, in fact, only make it more probable than another specified model; or, to put the matter so that it really has a defensible meaning, it can give reasons for preferring one model to another.

## Critical Evidence

Such an experiment, when it is well designed, is a challenge to Nature to opt for one of two replies. The great experiments of history are charged with this critical sense: the apocryphal experiment from the tower of Pisa which Galileo was long thought to have made, the interference of light, the work of Pasteur and that of Sherrington, the Michelson–Morley experiment, the charting of black-body radiation, the eclipse of 1919, the search for Yukawa's meson. In an absolute sense, at least some of these experimenters were mistaken, for they thought themselves to have established laws, which have since in their turn been ousted by others. But in the sense that matters, their experiments were as decisive as the discovery in a crossword that 'bezique' crosses 'syzygy' at the right point.

It has long been seen that some sciences, such as palaeontology, depend on this interlocking of evidence. By contrast, it has been thought (for example, by Collingwood) that the experimental sciences arrive at laws by a simpler accumulation of evidence. This distinction is false. Laws must be guessed by induction; they must be fitted together into an axiomatic model; and the model can only be tested by such critical devices.

The point is crucial; and it leads us to ask: How, in fact, does the scientist invent the nexus of primitive entities and their relations which make his model? The axioms of Euclid do not raise this question, because plainly they are simple experiences in geometry, and this is why they were long thought to be self-evident. But the entities which underlie an axiomatic description of Nature are not at all immediate to the senses. How does science come to isolate them?

### Experiments as Messages

Leibniz gives the clue to this when he says that the scientist must read the cryptogram in Nature. His hint has been neglected; but then, so has the whole fundamental problem.

Take some commonplace from the chemistry book, the simpler the better: say, the action of sulphuric acid on common salt. This reaction was known to Dr. Glauber in the seventeenth century. From that time, apothecaries knew what substances are involved, and more and more other reactions in which they take part. All these reactions were in a sense messages, that is, they had a systematic content; but chemists failed to read them, and chemistry remained incoherent, until their code was broken down. In effect, modern chemistry begins when Glauber's reaction could be written as

$$2\,NaCl + H_2SO_4 \rightarrow Na_2SO_4 + 2\,HCl.$$

This and the formulæ like it trace an order in the chemical actions by showing that they are all assembled from one set of code letters or elements.

The code does not stop there. It prompts the chemist to ask why S is so often coupled with $O_4$, and why the letter H moves about in so many of these messages. This is the familiar step in decoding which counts the frequencies of letters and of groups, and here it at once leads to the theory of valencies. From it we pass to physical theories, which seek a still more compact structure within the alphabet of ninety or so elements. The messages of physics can, in fact, be broken down, by these steps, first to electrons and unidentified nuclei, and then to a three-symbol Morse code of electrons, neutrons and protons.

### Code and Meaning

In this procedure, Nature is conceived as an assembly of processes (and not of objects or events). The sentences which describe these processes are thought to be a set of code messages. To trace the laws within the processes is then systematically to break down the code into its constituent symbols and their laws of arrangement. This is the most powerful form of the axiomatic method, for it recognizes that we do not analyse experiments but the sentences which record them.

This procedure, however, as yet has no criterion for preferring one axiomatic model to another. The choice between two ways of decoding the sentences, and the wish to pass from a code of ninety-odd symbols to one of three symbols, must be governed by a rational demand. This requirement is that the code shall make the content of information in the record as large as possible. In this context, information and meaning are identical; so that this is the demand that *the code shall make Nature as meaningful as possible*.

By way of example, consider two models each of which can account for the same set of experiments. The experiments are read as messages on the symbols and axioms of the two models; they therefore have in each case a content of information made up of sums

$$-\sum_i p_i \log p_i,$$

where the $p$'s are the probabilities that the symbols occur in their places by chance. The demand for the larger content of information therefore prefers the model in which the symbols have more free choices for their occurrence or behaviour. Succinctly, we are to prefer the less restrictive model; or, as Ockham put it, we are not to multiply hypotheses.

Even the messages of Nature, of course, do not reach us without noise. This background noise is provided by the experimental errors and ultimately by the coarseness of all observation. To this, Nature might have added a random process of her own, with no known law of distribution. But if so, we have not detected it. We set about the task of decoding on the assumption that nothing in the processes of Nature is meaningless.

### Direction of the Message

A message has only one dimension, and most scientific constructs have several. But since the message transcribes a process or experiment, plainly it singles out the dimension of time. Objects, events and structures are to be pictured within the code groups, where they can have their own function spaces. The direction of the message is the direction of time.

But, of course, a code message carries no mark of direction, and it might read forward or backward. Even a book of messages, or the whole record of the past, might be decoded in either direction; and its meaning would not be essentially different, with one exception. The exception is that we should not know which way time is running. This is an odd and final use of experiment: that we have to add one experiment of our own to the record, in order to fix the direction of time as we experience it.

---

# OBITUARIES

## Sir William Dampier, F.R.S.

SIR WILLIAM DAMPIER was born in 1867 and named William Cecil Dampier Whetham. His early work was published under that name; but later he changed his surname to that of his mother's family. His father and grandfather were prominent citizens of London, the latter being its Lord Mayor in 1878; but his own most vital interest lay in the country rather than the town. After taking his degree in Cambridge in 1889, he went to work in the Cavendish Laboratory under the inspiration of J. J. Thomson. The best-known result of his early work is his experimental proof that when liquids flow through tubes there is no slipping at the liquid–solid interface. Later he studied the motion of ions in liquids and developed methods for measuring ionic velocity which have since been used by others. With E. H. Griffiths he made accurate measurements of the conductivity and depression of freezing points of dilute solutions and showed that their results were in agreement with the ionic theory which Arrhenius had recently put forward. As a result of these studies he published in 1902 his book "The Theory of Solution", which was for a time the standard textbook on the subject.

In 1891 Dampier was elected to the fellowship at Trinity College, Cambridge, which he retained until the end of his life. After serving for some years as a College lecturer, he accepted the heavy duties of a College tutorship. In this office he showed a capacity for human sympathy which his many pupils gratefully remember; but his duties took up so much of his time that he had to drop his laboratory work. His mind, however, was very active. During this period he published books on eugenics and was collecting material for his "History of Science" (1929).

Meanwhile, with his love of the country and country pursuits, Dampier could not be satisfied with life spent entirely in Cambridge. He and his wife bought an estate in Devonshire, and problems connected with agricultural economics soon forced themselves on his attention. In 1917 he inherited a small family estate. At that time he was working part-time with Sir Thomas Middleton at the Food Production Department of the Ministry of Agriculture. He characteristically decided to put his agricultural ideas to the test by taking two farms near his estate and operating them through a manager. The scarcity of cheese during the First World War directed his attention to this product, and he set up a small cheese factory in connexion with his farms. Here the problem of using the surplus whey led him to experiments in the production of lactose, which eventually developed into a process used on a commercial scale.

The falling prices from 1920 onwards focused Dampier's attention on the relationship between money, prices and agricultural profits. He published his opinions on these subjects in the *Economic Journal* (1925) and in a book, "Politics and the Land" (1927).

The interest aroused by these publications and the reputation for sound judgment which Dampier had acquired in several forms of public service led to his being consulted by the Government on many problems of agricultural policy. Of these none was more important than those which led to the formation of the Agricultural Research Council. After the First World War, when it became clear that the Government would have to spend large sums in supporting scientific and medical research, the Department of Scientific and Industrial Research and the Medical Research Council were set up to encourage and regulate government expenditure and activity in these fields. No such body existed for agricultural science; but a number of laboratories devoted to agricultural research were being largely supported through public funds. Since these independent bodies were in some cases absorbing increasingly large grants, it became clear to the authorities that a body analogous to the Department of Scientific and Industrial Research or the Medical Research Council would have to be set up for agriculture. Dampier's tact and experience were of great value during the delicate negotiations which were necessary to bring the existing independent bodies into a state of mind favourable for setting up an Agricultural Research Council which would regulate their grants. Dampier became the secretary to the Council, and guided it in the difficult early stages until it became firmly established. He also took great interest in rural community councils.

Dampier was elected to the Royal Society in 1901, was knighted in 1931 and awarded the Gold Medal of the Royal Agricultural Society in 1936. He married Catherine Holt in 1897 and had five daughters. His loss will be deeply felt in Trinity College, to which he was so devoted and gave such good service.

G. I. TAYLOR

## Prof. L. B. Smyth

LOUIS BOUVIER SMYTH was born in Dublin in 1883 and died there on July 11, 1952. His father was Mr. Isaac Smyth of Dublin; his mother was French. He received his school education at Wesley College, Dublin, and entered Trinity College in 1902. He graduated in 1906, obtaining senior moderatorship in natural science with a large gold medal, awarded for first place on exceptionally high marks. In those days candidates took botany, geology and zoology, equal weight being assigned to each course during the four years; but for the degree a special course also had to be taken in one subject. Smyth took botany and was appointed as assistant to Prof. H. H. Dixon during the period when the present School of Botany was being built and the department organized. This happy collaboration continued for three years. He then accepted a post as naturalist in the Fisheries Branch of the Department of Agriculture and took part in several cruises to study, in particular, the phytoplankton. After a year there he was invited by Prof. John Joly to join his staff, and from 1911 until his death he continued in the Iveagh Geological Laboratory at Trinity College, Dublin. In 1911 also he married, very happily. He is survived by his widow.

Joly sent Smyth to work in Oxford under the late Dr. Arthur Vaughan, the leading English palæontologist of that period, and, on his return to Dublin, Smyth was appointed lecturer in palæontology. Then for more than twenty years he did all the exclusively honours teaching in the Geological Department in mineralogy, petrology, palæontology and geological map-reading. Sometimes also he had to lecture as Joly's deputy, and in six consecutive years he had the Senior Engineering Class on ore deposits. From 1931 until 1934 he occupied also the newly made post of lecturer in geography.

But Smyth's influence in Trinity College, Dublin, extended far beyond the geological laboratories. He joined the O.T.C. when it was first started, and was commissioned. He was in the Territorial Forces (Unattached List) in January 1915 and was promoted lieutenant 1916; but a disabling affliction denied him his wish of going on active service. The value of his military work may be realized on looking at the T.C.D. War List (1922); the total trained by the Corps was 1,490, with some 3,000 members of the University serving, and more than 460 names on the walls of the Hall of Honour. On committees too his quiet business-like manner and precision were of much value; most notable was his service as secretary of the University Council, and on the Board of Trinity College in his last years.

His first published work (1911) was with Joly, on the radium emanation in the soil. The rest were almost all in his sole name and appeared mainly in the *Scientific Proceedings of the Royal Dublin Society*, the *Proceedings of the Royal Irish Academy*, the *Geological Magazine* and the *Quarterly Journal of the*

*Geological Society of London*. In these the patient examination of the strata and the marshalling of the palæontological evidence linked up the geology of North Wales and the Irish coast. The first of the series dealt with the faunal zones of the Rush–Skerries Carboniferous Section, Co. Dublin, and further papers considered the strata at Malahide and at Ballycastle, Co. Antrim. The fine paper on the geology of Great Orme's Head (1925) led to the award of the Sc.D. degree. The Irish Academy published a similar contribution on the Carboniferous Rocks of Hook Head, Co. Wexford (1930). His papers gave detailed descriptions of fossils, notably of corals.

In 1934 Smyth succeeded Joly in the University chair of geology, which he occupied until his death. He devoted himself, unremittingly, to his teaching, and to the improvement of the Geological Museum and Department. He was never happier than when taking his students and overseas colleagues on geological expeditions—and few university cities have more varied geological interest close at hand than has Dublin. After a gap, occasioned by his teaching duties and illnesses, came "The Carboniferous System of North County Dublin" (Geol. Soc., 1950) and "A Viséan Cephalopod Fauna in the Rush Slates" (Roy. Irish Acad., 1951). A clear lecturer, a sympathetic teacher, loyally devoted to his University, a true friend—there are many who mourn his loss.

W. R. G. ATKINS

## Mr. C. E. N. Bromehead

CYRIL EDWARD NOWILL BROMEHEAD, formerly of the Geological Survey, died on December 4. He was born at York on January 8, 1885, and was educated at Marlborough and at Merton College, Oxford. He joined the Geological Survey of Great Britain in 1909 and was assigned as his first major task the 6-inch survey of a large part of the London area. With Henry Dewey he devised the present nomenclature of the gravel-terraces of the Thames Valley, and he became an authority on the geology and early history of London and particularly on the buried tributaries of the Thames such as the Fleet and Ty Bourne.

In the First World War he served in Flanders and was severely wounded. He returned to the Geological Survey in time to take part in explorations in Derbyshire which led in 1919 to the drilling of Britain's first oil-well at Hardstoft.

In 1922 he was appointed district geologist in charge of Yorkshire. Employing techniques of stratigraphical palæontology then being devised by W. S. Bisat, Sir Arthur Trueman and W. B. Wright, he and his staff became experts on the Upper Carboniferous rocks. In fifteen years his unit made a detailed revision of most of the coalfield and its borders—an area of nearly 1,000 square miles—and sent to the press the relevant maps and memoirs as well as a new edition of the memoir on the "Concealed Coalfield of Yorkshire and Nottinghamshire". These publications have proved invaluable in subsequent developments of the coalfield.

In 1935 Bromehead took charge of geological work in Southern England, where mapping was proceeding in Kent. For much of the next ten years, however, his duties were connected with the Second World War, and throughout this time his knowledge and experience were always at his colleagues' service. He relinquished some of his responsibilities in 1945 and retired in 1949.

During this last period his interest in the origins of geology and related arts (he was a founder-member of the Society for History of Science) was revealed in two presidential addresses to the Geologists' Association on the early history of practical geology and mining in Britain, and in papers on antiquarian subjects—'eagle-stones', loadstones, 'murrhine', early water-supply and museums—in which a high order of classical scholarship was delightfully blended with geology. He also wrote on oil, reservoir-dams and fluorosis.

Profoundly influenced in his youth by what was then known as the 'Oxford Movement', Bromehead practised religion with characteristic thoroughness. He is remembered with affection by the many who experienced his kindliness and culture, his wisdom and, not least, his firmness in moments of crisis.

WILFRID EDWARDS

## Mr. R. S. Styles and Mr. F. W. Campbell

RONALD STEPHEN STYLES and Frederick William Campbell, who were attached to the Division of Radiophysics of the Commonwealth Scientific and Industrial Research Organization, Australia, were killed in an aircraft accident near Sydney on October 27 while engaged on research in cloud physics and natural rain formation.

Styles and Campbell were on a routine flight in an R.A.A.F. Dakota fitted for cloud 'probing' using microwave radar and special instruments designed in the Division of Radiophysics for observing cloud temperature, liquid-water content and cloud droplet spectra. The aircraft had been investigating clouds over the sea and reported that it was descending from 6,000 ft. to 2,000 ft. through low cloud and heavy rain preparatory to returning to base. It failed to report at the next check-point, and an intensive emergency search was immediately organized. Oil, wreckage and a half-inflated rubber dinghy were found a short distance out to sea, and some items recovered were identified as belonging to personnel on the aircraft; all on board, including an R.A.A.F. crew of four, were killed.

Mr. Styles was born in Sydney, New South Wales, in 1926. At the University of Sydney he took a course combining physics and electrical engineering. He graduated with the double degree of B.Sc. and B.E. and joined the Radiophysics Division as a research officer in March 1948. His initial work concerned radio aids to aircraft navigation, to which he made valuable contributions. He was then transferred to work on rain and cloud physics, and his obvious ability and enthusiasm soon led to his taking a major part in airborne observations of natural rain. His observations of the development of non-freezing clouds to give rain are of particular interest. He also contributed significantly to the development of instruments in this field and displayed a marked ability for organizing, implementing and analysing results in this difficult field of research. He leaves a widow and an infant son.

Mr. Campbell was born in 1915, at Norseman, Western Australia. After successfully completing a radio course at Perth Technical College in 1934, he spent the pre-war years as a radio engineer in Perth. During the Second World War he served with the Royal Air Force, rising to the rank of squadron leader. He undertook specialized radio and radar courses at Prestwick, Great Malvern and elsewhere, was mentioned in dispatches for meritorious technical services and was finally senior radar officer to No. 38 Group, R.A.F. After the War he was appointed to the Department of Civil Aviation in Sydney. He joined the staff of the Commonwealth Scientific and Industrial Research Organization in August 1947 as a technical officer, and was an active member of the team carrying out flight trials and experiments on radio aids to navigation. He had a first-class knowledge of aircraft radio equipment. He later joined the Rain and Cloud Physics team and for several years worked in partnership with Mr. Styles. Mr. Campbell was married and had two young children.

The death of these two young men is a tragic loss to Australia. Their work in the field of rain physics was just beginning to bear fruit, and their loss means a serious setback to the research in cloud physics which has progressed so well in Australia.

### Dr. E. H. Hunt

Dr. Edmund Henderson Hunt was educated at Harrow and Balliol College, Oxford, where he took a first in physiology under J. B. S. Haldane, and went on to St. Bartholomew's Hospital, London, where he added the F.R.C.S. to his M.Ch.(Oxon.). He then accepted the appointment of chief medical officer to the Nizam's State Railway, Hyderabad, more or less as a temporary measure, but he found his life's work there. Apart from the constant pressure of his medical and surgical work at the Lallaguda Hospital, he developed a large private practice, which took him into all parts of the great city. The wide first-hand knowledge of the country he so gained led him to interest himself in anthropology and archæology. He was a fellow of long standing of the Royal Anthropological Institute, and published the results of important excavations of the Hyderabad urn-burials, and other papers, including a remarkable contribution on black magic, from the clinical point of view. His incomparable photographs of Ellora and Ajanta were widely known and did much to encourage the growing interest in Indian art. He was, also, a collector of Celadon. On retirement, he became interested in scientific bee-keeping, and was chairman of the Farnham Association and a member of the National Honey Show committee. To these activities must be added the many research activities in India, from geology to archæology, which would have been impossible without his helping hand. He was a true colleague to any research worker who approached him, a real friend of India, and an unforgettable personality.

K. de B. Codrington

## NEWS and VIEWS

### Queen Elizabeth College

The granting of a Royal Charter to Queen Elizabeth College, University of London, marks the beginning of a new phase in the work of what has hitherto been known as King's College of Household and Social Science. Beginning as a department of King's College for Women in 1908, it gradually developed research and teaching in the scientific aspects of household and social work, until in 1920 there was introduced the first degree in these subjects—B.Sc. (Household and Social Science). By 1928, the department became an independent school in the University of London under the title of King's College of Household and Social Science. It played a prominent part in the development of dietetics as a specialized study, and began, in 1933, the first courses leading to a diploma in dietetics. Now, with its Royal Charter and its new name, Queen Elizabeth College (after Queen Elizabeth, the Queen Mother) is breaking new ground. From October 1953 it will be training men and women undergraduates in the science of nutrition, leading to the new degree of B.Sc. (Nutrition). So far as we know, there is no other university in Britain which gives an undergraduate course for a first degree in this subject. A brief account of this degree and of the new degree of B.Sc. (Household Science) was given in *Nature* of August 9, 1952, p. 226.

### 'Krilium'

In December 1951 publicity was given to the discovery of a new way of improving soil structure by the use of certain synthetic polyelectrolytes produced by Monsanto Chemicals, Ltd., under the trade name 'Krilium' (see *Nature*, 171, 7; 1953). Other conditioners were afterwards announced by other manufacturers. During 1952 experiments have been made with 'Krilium' by several agricultural research institutes in Britain and by the National Agricultural Advisory Service under the auspices of the Agricultural Research Council. The substance used was supplied by Monsanto Chemicals, Ltd., as 'Krilium' (*CRD*. 189) and described as a sodium salt of polyacrylic acid. This was the earliest available soil conditioner and in its original form proved somewhat difficult to incorporate in moist British soils. The results of the 1952 experiments have now been examined. They were not expected to be more than preliminary, and no definite conclusions, therefore, can be drawn at this stage of investigation. The initial findings can be summarized as follows. (1) Improvement in structure after treatment was apparent in many of the soils tested. (2) The uptake by plants of major and minor nutrients was not adversely affected. (3) The activity of soil micro-organisms was normal. (4) No conclusive evidence was obtained that the application of 'Krilium' caused any significant increases in crop yields of field or of glasshouse crops, though in certain cases increased yields were recorded. Much more experimental evidence on the best method of incorporation, degree of aggregation and persistence of structure of treated soils, and the relation of these to crop yields is required before any definite conclusion can be reached. Towards the end of the year Monsanto Chemicals, Ltd., made available a new soil conditioner, described as a calcium salt of vinyl acetate – maleic acid copolymer. This was found to be more easily incorporated in soil and is stated to have better soil aggregating properties than *CRD*. 189. Experiments will be continued in 1953 and the results, when complete, will be published in the usual reports and journals.

### Associate Directorship of the U.S. National Science Foundation

The new post of associate director of the United States National Science Foundation has been filled by Dr. Paul E. Klopsteg, at present the assistant director for mathematical, physical and engineering sciences of the Foundation, and his place is being taken by Dr. Raymond J. Seeger, the programme director for physical sciences in the Foundation. In his new appointment, Dr. Klopsteg will be responsible for assisting the director and the deputy director of the Foundation in following closely the development of relationships with universities and with other Federal agencies; he will also handle special assignments of importance to the scientific programmes of the Foundation. Dr. Klopsteg is a graduate of the University of Minnesota, and in 1916 he gained there his Ph.D. in physics. His professional career has been devoted to the administration of research, and before the Second World War he was president of the Central Scientific Co. During the War he served with the Office of Scientific Research and Development as chief of Division 17, Physics and Special Devices, of the National Defense Research Committee, which developed important equipment and devices for war-time use. Later he was assistant chief of the Office of Field Service, which organized and directed the assignment of scientific consultants to the various theatres of war, and in this capacity he served in Australia and New Guinea as chief of the Research Division, General Headquarters, Southwest Pacific. Dr. Klopsteg has been chairman of the board of governors of the Argonne National Laboratory and is chairman of the Committee on Artificial Limbs of the National Research Council. He is at present on leave of absence from his post as professor of applied science and director of research of the Northwestern Technological Institute, Evanston, Ill.

## International Association for the Exchange of Students for Technical Experience

The fifth annual report of the International Association for the Exchange of Students for Technical Experience (pp. 56; from the secretary, J. Newby, at the Imperial College of Science and Technology, London, S.W.7) records continued progress both numerically and geographically: 3,493 students were sent abroad during 1952, an increase of 1,060 over the previous year. Yugoslavia joined the Association in January 1952, and the Saar and Turkey were represented at the conference of organizers. One large company with international interests selected in 1952 twelve undergraduate students for nomination to its overseas connexions and received twelve students in Great Britain selected by its overseas counterpart. Places available abroad for students of business administration and commerce increased to 112 as compared with 35 in 1951. More students were accepted than were sent in the following countries (numbers shown in brackets): Sweden (547), Great Britain (114), United States (47), Switzerland (37) and Spain (2). Of countries sending more students than they accept, Austria (161), Germany (148), Netherlands (118), Finland (94), Denmark (93) and France (51) show the largest excesses.

Since the establishment of the Association in 1948, some 1,440 industrial and other organizations have received foreign students under the scheme; it is estimated that during the summer of 1952 international industry and commerce contributed more than £161,000 to the Association's programme. The report includes an analysis of industries participating in the exchange and also of the subjects which participating students were studying. A list of institutions and firms taking part in the scheme is included under each country, and a supplement gives further details of exchanges in which Great Britain participated in 1952, when 488 students were sent abroad and 602 foreign students were received and placed. Travelling arrangements appear to require improvement, but relations between the students and other workers were entirely satisfactory, and an interim evaluation of the reports received on British students indicates that 1952 has been the best year both in the numbers sent abroad and in the service given.

## International Trade in Agricultural Machinery

Technically there is scope for much greater use of agricultural machinery, according to a report issued by the Commonwealth Economic Committee, "A Survey of the Trade in Agricultural Machinery" (No. 36; pp. 174. London: H.M.S.O., 1952. 7*s.* 6*d.*). Rises in the prices of agricultural machinery have been considerably less than those of the principal agricultural commodities, while the urge for greater agricultural production together with widespread increases in the cost of labour should combine to increase the demand for mechanization. Figures relating to world exports of agricultural machinery show that values rose from £25 million in 1938 to £300 million in 1951. In the post-war period, the United Kingdom has become the second largest manufacturer of tractors in the world, although she is still greatly outdistanced by the United States, where the production is four and a half times as great. The report shows that recent developments have been directed towards reducing manual labour on farms, or mechanizing processes which call for seasonal peaks in labour. To reduce labour costs, balers, loaders and handling gear, electric fences and dung spreaders are being increasingly used, while to decrease the need for casual labour, root harvesters in Europe, sugar-cane harvesters in Australia and cotton harvesters in the United States are being adopted. An important aspect of development has been the adaptation of standard implements to new tasks as, for example, the application of rotary cultivators and combine harvesters to crops of irrigated rice in India.

## Scientific Methods in the National Gallery Laboratory

An article on "Scientific Method and the Art Gallery", by Mr. F. I. G. Rawlins and Dr. A. E. Werner, of the National Gallery Laboratory, London, has been published in *Science Progress* (90, No. 160), in which the authors review developments at the Laboratory since 1939 and show how the application of science has aided the care of pictures. Studies in the effects of temperature and humidity changes and the introduction of air-conditioning are recorded. Recent work in the use of X-rays, ultra-violet and infra-red rays in the examination of works of art is discussed, and some details are given of chemical and physical techniques now used in the treatment of pictures.

## *Studies in Conservation*: Journal of the International Institute for the Conservation of Museum Objects

The appearance of a new periodical is in these days an event of prime importance, and especially if that periodical may interest comparatively few members of the public, because then the venture is even more hazardous. The first number has now been published of *Studies in Conservation* (1, No. 1; October 1952. Pp. 48. London and Edinburgh: Thomas Nelson and Sons, Ltd; about 2 Nos. a year, 21*s*. net a year), which is the journal of the International Institute for the Conservation of Museum Objects, and it raises this very issue, for, although the public to which the journal is addressed is small, it is very important inasmuch as the preservation of the world's art treasures depends on the standards maintained in practice by a relatively small number of professional conservators. When "Technical Studies in the Field of the Fine Arts" discontinued publication, conservators were left without any medium of communication of a strictly comparative type; it is this gap that it is hoped the new journal will fill. The policy adopted and the scope of the work covered by the journal is well expressed in the editor's preface: "Whereas nothing less than the best—and that implies the most meticulous—in the way of scholarship will suffice, there is every reason why studio and laboratory processes should receive equal prominence. Knowledge advances by the mastery of technique . . .". This statement is fully upheld by the contents of this first number, which contains articles written by authorities in their respective subjects covering a wide field; they include an account of a detailed investigation of the Dirk Bouts altar-piece, an interesting X-ray examination of an ancient metal object, and a record of valuable data concerning the hygroscopic behaviour of wood. All the investigations have yielded results that are of great interest to those engaged in the conservation of museum objects. The number closes with reviews of books dealing with the treatment of pictures, metallurgy in antiquity, defects of paint films and the surface chemistry of solids. The editor and publishers are to be congratulated on the production of a most acceptable first number, both on account of the choice of material and the quality of the printing and the reproductions. The journal should appeal not only to those who are directly concerned with the problems of conservation but also to the far wider circle of those who take a general interest in museum objects.

## New Spectrophotometer for Visible and Near Infra-red Radiation

A NEW spectrophotometer, the '*SP*. 600', for accurate colorimetric measurements within the visible and near infra-red regions of the spectrum, has been designed by Unicam Instruments (Cambridge), Ltd., of the Arbury Works, Cambridge. With this instrument the analysis of a sample, or comparison with a reference substance, can be speedily carried out. Over the greater part of the spectral range the band-width is about 30 A., and this is sufficiently narrow to reduce to a minimum effects commonly associated with spectral impurity at the selected wave-lengths. The instrument controls are simple to operate and consist of the following: a wave-length dial, calibrated in 10-A. divisions from 3600 to 4500 A. and then in 20, 50 and 100 A. to 10,000 A.; controls for slit width, dark current, transmission or optical density; and a selector switch for a red or blue (for use below 6500 A.) photocell. The light source is a tungsten lamp, and the optical system is a simple Littrow monochromator with glass prism. The photocell output current is amplified. Bias and high-tension voltages are provided by dry batteries housed underneath the spectrophotometer, but lamp and heater supplies must be obtained from an external 12-V. source. The illustrated pamphlet describing the instrument includes a transmission/wave-length graph of Chance *O.N.* 12 didymium glass taken on a standard form of the spectrophotometer, and details of the dimensions and accessories of the instrument.

## Educational Grants for Training in Plastics

THE trustees of the Plastics Industry Education Fund have decided as an experiment to allot up to £2,000 over a period of two years for maintenance grants for students attending a new two-year full-time course in plastics at the Borough Polytechnic, London. The course, which is for a minimum of eight students of about sixteen years of age who have taken the General Certificate of Education, will follow the syllabus of the City and Guilds of London Institute, leading to the diploma of the Plastics Institute at the end of the second year. Applications to attend the course should be made to the Principal, Borough Polytechnic, London, S.E.1. The trustees have also decided to allot £2,000 for capital equipment in technical colleges in Great Britain, which will include the Acton Technical College, the College of Technology, Birmingham, the Newton Heath Technical College and the National College of Rubber Technology.

## Awards for Technical Articles on Radio

THE Radio Industry Council is continuing its practice of making awards of 25 guineas, up to an average of six a year, for technical articles on radio published during the past year in any public journal. The principal criteria in judging will be the value of an article in making known British achievement in radio and electronics, originality of subject, technical interest and presentation and clarity. Only authors whose salary is not mainly or wholly gained by writing are eligible. They should submit their work (five copies if possible) to the Secretary, Radio Industry Council, 59 Russell Square, London, W.C.1, from whom all further particulars can be obtained.

## Research Fellowships at Government Scientific Establishments

FOR several years Ministry of Supply research fellowships, tenable at Harwell and certain other Ministry of Supply establishments, have been offered annually, and now a small number of similar research fellowships is being instituted at other government scientific establishments. A considerable choice of subject will be allowed to research fellows, provided that it falls within the field of work covered by the establishment to which they are attached. The fellowships will be tenable for three years and will carry benefits under the Federated Superannuation System for Universities. Remuneration will depend on individual merit and experience and will be £800–1,000 a year inclusive for senior awards and £500–700 for junior awards. The fellowships will be advertised by the Civil Service Commission as the occasion arises, and advertisements for the first awards should appear within the next few weeks.

## Colonial Service: Recent Appointments

THE following appointments in the Colonial Service have recently been announced: B. G. Kinloch (assistant game warden, Uganda), game warden, Uganda; A. F. W. Sheffield (principal agricultural officer, Nigeria), deputy director of agriculture, Eastern Region, Nigeria; E. H. Probyn (senior assistant conservator of forests, Cyprus), conservator of forests, Tanganyika; P. E. Glover (research officer (botanist), East African Trypanosomiasis and Tsetse Research and Reclamation Organization), chief field geologist, Kenya; T. H. P. Hartley and J. A. Howarth (agricultural survey officers, Gold Coast), principal agricultural survey officers, Gold Coast; F. A. Leeds and D. Westwood (agricultural officers, Gold Coast), senior agricultural officers, Gold Coast; L. Lotringer, J. A. Makinde, S. Z. Moczarski and G. E. Okiy (agricultural superintendents, Nigeria), agricultural officers, Nigeria; K. V. W. Nicholls (meteorologist, East Africa High Commission), senior meteorologist, British Caribbean Meteorological Service, Trinidad; H. T. Shewan (agricultural survey officer, Gold Coast), principal agricultural survey officer, Gold Coast; B. D. A. Beck, plant breeder, Nigeria; S. R. Chant, plant pathologist, Nigeria; C. M. Grieve, agricultural officer, British Honduras; A. D. H. Joblin, agricultural officer, Uganda; R. G. Poultney, pasture research officer, Kenya; J. H. Proctor, entomologist, British Guiana; R. MacDonald, geologist, Uganda; R. H. Cammack, scientific officer (mycologist), Nigeria; A. G. Smyth, soil scientist, Nigeria; R. F. Coughlan, veterinary research officer, Federation of Malaya; C. J. Price, veterinary officer, Uganda; J. G. Tremlett, veterinary officer, Northern Rhodesia; E. M. McWatt, veterinary officer, British Guiana; T. R. Paton, scientific officer (soil chemist), North Borneo; J. D. Randall, statistician, East Africa High Commission; W. W. Reece, stock development officer, North Borneo; R. A. Eyre-Smith, livestock improvement officer, Kenya; R. L. Sykes, leather chemist, East Africa High Commission; Miss M. S. Timpson, computer, Uganda; R. J. Wedderburn, assistant conservator of forests, Nigeria.

## The Night Sky in February

New moon occurs on Feb. 14d. 01h. 10m. U.T., and full moon on Feb. 28d. 18h. 59m. The following conjunctions with the moon take place: Feb. 5d. 18h., Saturn 8° N.; Feb. 16d. 23h., Mars 5° S.; Feb. 17d. 09h., Venus 2° S.; Feb. 19d. 14h., Jupiter 6° S. Mercury, in superior conjunction on February 2, is not well placed for observation until later in the month. On February 14 and 28 it sets at 18h. and 19h. 15m., respectively, and can be seen in the western sky after sunset in the latter part of the month. Venus is an evening star and sets at 21h. 05m., 21h. 35m. and 21h. 50m. on February 1, 14 and 28, respectively. The visible portion of the illuminated disk varies between 0·51 and 0·34, and the stellar magnitude is about − 4·2. Mars is visible in the early evening hours, its time of setting being about 20h. 50m. during the month. Its stellar magnitude is 1·3; in the early part of the month it lies a little south of λ Piscium, and towards the end of the month a little south of ε Piscium. Jupiter sets at 1h. 15m., 0h. 25m. and 23h. 45m. on February 1, 14 and 28, respectively, its stellar magnitude varying between − 2 and − 1·8. At the end of the month the planet lies a little south of δ Arietis. Saturn rises at 23h. 40m., 22h. 45m. and 21h. 55m. at the beginning, middle and end of the month, respectively. Its stellar magnitude is 0·3, and it lies a little north-east of α Virginis during the whole of February. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Feb. 2d. 1h. 37·6m., ρ Leon. (*R*); Feb. 4d. 2h. 58·2m., *q* Virg. (*R*). *R* refers to reappearance. A partial eclipse of the sun, invisible at Greenwich, takes place during Feb. 13–14. It begins on Feb. 13d. 23h. 12m. at lat. 21° 55′, long. − 111°, and ends on Feb. 14d. 02h. 45·6m. at lat. 68° 27′, long. 164° 08′. The magnitude of the greatest eclipse is 0·760 (sun's diameter 1·0).

## Announcements

The Third General Assembly and International Congress of the International Union of Crystallography will be held in Paris during July 21–28, 1954. These dates have been chosen in consultation with the French National Committee for Crystallography and with the national committees of all the adhering bodies. Further particulars of the meeting will be given from time to time in *Acta Crystallographica* and elsewhere, or may be obtained from the general secretary of the Union, Dr. R. C. Evans, Crystallographic Laboratory, Cavendish Laboratory, Cambridge.

The spring conference of the Geographical Association will be held in the Diocesan Training College, Lincoln, during April 7–11, under the presidency of Dr. O. J. R. Howarth. The programme mainly consists of excursions of various sorts, but, in addition to the usual social functions, there will be a number of lectures, including the presidential address for 1952 by Prof. F. Debenham, and also an exhibition of maps, plans, books, etc. Application forms, which must be returned by February 16, and further information can be obtained from the honorary conference secretary, Miss Margaret Goodrich, Training College, Lincoln.

A symposium on molecular structure and spectroscopy, on the lines of those of previous years, will be held in the Department of Physics and Astronomy, Ohio State University, during June 15–19. The interpretation of molecular spectroscopic data as well as methods for obtaining such data will be discussed, and, in addition, there will be sessions devoted to aspects of spectroscopy which are of current interest. Further details can be obtained from Prof. Robert A. Oetjen, Department of Physics and Astronomy, Ohio State University, Columbus 10, Ohio.

List No. 7 (pp. 77, December 1951) of "Scientific Papers published in the Middle East", now issued by the Middle East Science Co-operation Office, Cairo, includes the papers received by that Office during November 1, 1950–September 30, 1951, and covers Afghanistan, Cyprus, Egypt, Iran, Iraq, Israel, Lebanon, Pakistan, Sudan, Syria and Turkey. There is the usual list of periodicals, arranged by country; the papers themselves are arranged by sciences and technologies according to the decimal classification.

The Ministry of Agriculture and Fisheries is offering the following scholarships for rural workers, or the children of rural workers, of seventeen years of age or more: ten senior scholarships, tenable at universities or colleges, for degree or diploma courses in an agricultural subject or veterinary science; sixty junior scholarships and six extensions for existing holders, tenable at farm institutes, for one-year courses. Selection is by interview only. Further information and forms of application (to be completed by March 31) can be obtained from the Secretary (Room 314), 1 Cambridge Terrace, Regent's Park, London, N.W.1, or from the education offices of County Councils.

# GEOPHYSICAL PROSPECTING

THE European Association of Exploration Geophysicists held its third meeting at the Stadthalle, Hanover, during December 3–5. More than a hundred and fifty members and guests from various countries in Europe and the United States attended. At the business meeting held on the first day, the final arrangements for the publication of the Association's journal were announced and approved. The journal will be entitled *Geophysical Prospecting* and will be published quarterly, the first issue appearing, probably, in March. Twenty papers were presented at the technical sessions. They comprised ten on seismic, seven on gravity, one on magnetic and two on electric problems of prospecting.

Few people outside Germany are aware of the remarkable progress which has been made by geophysical firms in that country in the application of seismic methods underground in mines. The location of faults, metalliferous veins, and the accurate mapping of sinuous or faulted veins are problems on which considerable successful work is being done, and one of the papers presented at the meeting, by H. Linsser (Germany), described the interpretation of the seismic sub-surface records by a statistical method designed to improve accuracy. An interesting description was given by H. von Helms and H. W. Maas (Germany) of recent marine seismic observations undertaken in the Baltic Sea. By means of these observations, perhaps the first of their kind to be made off a European coast, it became possible to fill in the gaps of a seismic section observed on land between Flensburg and Kiel.

The existence of multiple reflexions sometimes causes difficulties in the interpretation of seismic reflexion records. It has been the general tendency for these multiples, when they exist, to occur in areas which, structurally, have been little disturbed, but a paper submitted by H. Richard (France) demonstrated the existence of multiples in certain areas marked by steep dips and faulting. A particularly interesting case was the simultaneous recording of multiple reflexions from horizontal beds within a graben, and other oblique multiple reflexions from the steeply inclined beds at the boundaries of the graben. In describing the possible paths traversed by the reflexions, the author made some startling suggestions and introduced conceptions which were novel. The succession of seismograms obtained along a section across the graben, when placed in sequence below each other, furnished an unusual picture of the shape of the geological structure, the vertical lines of reflexions in the early parts of the seismogram depicting the horizontal beds within the graben and the later oblique lines of reflexions, forming overall the shape of a V, depicting the two inclined boundaries of the graben.

The subject of wave-energy return by diffraction from faulted beds, already discussed at a previous meeting in London[1], was again raised through a paper presented by R. Koehler (Germany). A practical example was described which suggested that 'reflexions' caused by diffraction can almost certainly be detected if they arise from shallow beds in a faulted area with wide fracture zone; but the effect from deeper beds is negligible. Two papers, from J. Schoeffler (France) and H. J. Dürbaum (Germany), dealt with the frequently considered problem of improving seismic interpretation by taking into account the departure of the actual ray-paths from the normally assumed straight-line paths.

The Department of Geophysics of the Amt für Bodenforschung, with the co-operation of the oil companies concerned, is engaged in a compilation of the data furnished by well velocity-surveys carried out in north-west Germany, on the lines of a similar compilation undertaken in the United States which has been of considerable value to American geophysicists. The results of this German work to date, based on seventy-four well velocity-surveys carried out during a period of eighteen years, were described. The data covered depths down to nearly six thousand feet, and interesting comparisons were made with the corresponding data from the United States.

A useful electronic device for overcoming the effects of static on seismic shot signals was described in a paper submitted by A. T. Dennison and F. A. Roberts (Great Britain). Pronounced static can cause serious delays in seismic long-range refraction surveys, and a device such as this should prove invaluable in these circumstances.

The seismic session of the meeting was rounded off with two interesting papers describing methods of ascertaining the velocity of sound waves in rock samples. In a demonstration of the first method, by H. Baule (Germany), supersonic pulses were transmitted through a cylindrical core of the rock specimen by a magnetostrictive driver attached to one end. The pulses were received at any chosen distance along the core by a small crystal pick-up resting on the specimen. The transmitted pulse and the wave form of the received disturbance were displayed stationary on a cathode-ray tube, together with a time scale furnished by a quartz clock, and the travel-time could thus be measured. Observations made at different distances enabled a time-curve to be drawn from which the velocity could be accurately determined. The second method, described by E. Müller (Germany), has the advantage that only quite small specimens of the rock are required. The sample is prepared by making a single cut, so as to produce a plane face, and then it is dipped in a fluid of known sound velocity. On the plane face of the sample a minute explosion is produced by an electric spark, and the two wave-fronts produced in the fluid by the longitudinal and transverse waves propagated through the specimen are photographed by the schlieren method. The angles between each wave-front and the plane surface of the specimen are measured, and the velocities and elastic constants thereby determined.

The session on gravity prospecting opened with a paper by B. J. Hofman (Holland) describing developments in marine gravity surveying. Experience has shown that remote-control underwater instruments have many advantages, and operational costs using such instruments are lower than with other systems utilizing land instruments on tripods or in diving bells.

The uses of the first, second and even higher derivatives of gravity in the interpretation of field observations were considered in papers by V. Baranov (France), O. Rosenbach (co-authors R. Koehler and E. Wirth) and B. Kosbahn (Germany). A particularly interesting contribution by S. Saxov (Denmark) shed considerable light on the relative values of the various derivative methods in emphasizing structural anomalies at different depths.

Prof. J. Goguel (France) described certain features of the geological interpretation of the gravity map of the Paris basin, and Prof. O. Vecchia (Italy) gave a detailed account of the regional structure of northern Italy deduced from gravity measurements. The results of magnetic investigations over the palæozoic massif of Serpont, in Belgium, were described by C. Gaibar-Puertas (Spain) and E. Hoge (Belgium). The applications of conformal representation in the interpretation of the results of telluric current surveys were considered in a detailed communication by G. Kunetz and J. C. de Gery (France). The final paper at the meeting dealt with the application of geophysics in the search for further supplies of drinking-water in Western Germany, and it is interesting to learn that considerable success has attended the application of geoelectrical measurements in quite a number of the hydrological problems which are involved.

D. T. GERMAIN-JONES

# SCIENCE MASTERS' ASSOCIATION

## ANNUAL MEETING

THE annual meeting of the Science Masters' Association was held in the Chemical Department of the Royal College of Science, London, S.W.7, during December 30, 1952–January 2, 1953. The general theme of the meeting was "Science in the Service of the Community", and, with the co-operation of the heads of the science departments of the Imperial College of Science and Technology, the Science Museum, the Metropolitan Police Forensic Laboratory, the scientific departments of the London County Council and members of the Association, the widespread use of science in the modern world was adequately and realistically displayed.

In his presidential address, Sir Graham Savage, until recently the education officer to the London County Council and previously for many years chief staff inspector to the Board of Education, made a survey of the teaching of science during the past hundred years. He illustrated his talk by quotations from many sources not usually met with in the normal educational circles, and concluded by looking forward to a possible expansion of scientific teaching, expressing the hope that greater freedom would be granted to the qualified teacher to enable him to make the most of the material at his disposal or of that which he might be allowed to acquire.

Mr. L. C. Nickolls, director of the Metropolitan Police Forensic Laboratory at New Scotland Yard, London, in a lecture enlivened by many touches of humour, described the application of scientific methods dealt with by his Department. Illustrating his lecture by examples taken from his own wide experience, he emphasized the necessity for wisdom or common sense, as well as for highly skilled technical knowledge, in the solution of practical problems. He appealed to science masters to try to instil into their students the need for wisdom. At present, he said, too many highly skilled workers are becoming technicians, and too few are becoming scientists. Forensic science demands the use of a little science but a lot of common sense as, for example, when a member of his staff identified by means of detailed analysis two specimens of paint as containing the same metallic elements and declared them identical, while omitting to observe that one was green and the other brown. Mr. Nickolls described the work of his Department as falling under four headings: to tell whether a crime has actually been committed; to say who did it; to supply corroborating evidence; and to increase the weight of the evidence when the cases are presented before the courts. These points were most adequately illustrated by photographs of activities which had been brought to the notice of the Laboratory.

The heads of the Departments of Botany, Physics and Organic Chemistry of the Imperial College of Science and Technology—Prof. W. Brown, Prof. S. Devons and Prof. R. P. Linstead, respectively—described work done recently in their Departments. Prof. Brown, in dealing with the problem of plant diseases, said that it would be possible only to skate lightly over the field of study of pathology in plants. His aim, therefore, would be to give the main lines along which one proceeds to deal with the problem. As contrasted with veterinary, and especially medical, work, the methods of plant pathology have to deal almost entirely with populations and not with individuals. Inasmuch as a plant disease almost invariably damages the plant so that it rarely recovers, the plant pathologist is more concerned to ward off disease than to deal with it once it is fully established: the adage, 'prevention is better than cure', appeals to him with particularly strong force. The lines of defence include such things as improved cultural practice, protective fungicides and bactericides, breeding of resistant types of plants and the control of the spread of infective material. In connexion with the last-named, there exists considerable legislative repercussions for the unwary. Prof. Brown's lecture was illustrated by museum specimens, cultures of pathogenic organisms and with lantern slides. Prof. Devons dealt with the electromagnetic radiation from the nuclei, discussing the factors involved and the methods used in investigating the phenomenon. Prof. R. P. Linstead discussed the oxidation-reduction systems and, in particular, the hydrogen transfer from donor to acceptor molecules, giving as the most remarkable those changes which take place in the living cell. The mechanism of some transfers of hydrogen and the energy changes involved were discussed.

Mr. F. A. Meier, of the University of London Institute of Education, gave one of his customary lecture demonstrations, this time on a theoretical and experimental approach in the teaching of the M.K.S. systems of electrical units. Mr. Meier can always be relied upon to attract and hold the attention of a large audience of physicists, and this year was no exception to the rule.

New semi-micro experiments and their application to qualitative analysis were described by Mr. H. Holness, of the South West Essex Technical College. This was followed by a visit to the College, where students demonstrated the new techniques and apparatus, and where members were given an opportunity of using some semi-micro apparatus for themselves. Dr. F. Sherwood Taylor, director of the Science Museum, South Kensington, outlined the work there, both in a lecture and by a tour of the Museum. He described his efforts to increase the co-operation between the schools and the Museum, and to display to the general and to the specialized and informed public alike how scientific achievements have and can impinge upon the life of mankind. Dr. Sherwood Taylor also indicated that were there a suitable demand he would be prepared to consider following the lead of the National Gallery and organize exhibitions of museum material outside London.

Dr. T. P. Colclough, of the British Iron and Steel Federation, showed how increased efficiency in the manufacture of steel depends upon the skilful use of the scientific worker, and that the industry, with its equipment costing millions of pounds, can only function successfully if science is applied at every stage and in every process; there is therefore a need and an opening for more, and for more highly trained, scientists.

The Departments of the Medical Officer of Health and of the County Engineer of the London County Council provided lecturers and demonstrations of the direct application of science in modern life. An informative lecture upon the drainage of London from the earliest times to the present day, with a discussion of the many problems involved, showed how life in a congested city can be maintained and also the risks to which those who are involved in the sewerage system are exposed. A colour film of this work was shown in the County Hall, London, after which the laboratories of the Chemist-in-Chief were inspected. In these laboratories more than twenty-five thousand samples are investigated annually, including samples of air from the London tunnels, water from the rivers, from the wells in the Council's institutions, from swimming pools and baths, paints and building materials, laundry materials and fabrics with their resistance to washing, and the control of all stages of sewage treatment. Time permitted only a brief inspection of the extensive display set out by the twenty-six graduate chemists and their twenty-eight assistants.

However, the most spectacular lecture of the meeting was undoubtedly that given by Dr. C. W. W. Read, director of education for West Sussex and chairman of the West Sussex Beekeepers Association, who showed how a method has been devised for inseminating instrumentally the virgin queen honey-bee while still in captivity. Hitherto mating has been done on the wing and therefore beyond human control. A special micro technique is involved, and this was demonstrated both by means of the apparatus and by a coloured film of all the processes involved. By suitable sized screens in the hives, the queen bees and the males can be separated from the 'workers'. The drones can then be marked for identification purposes, so that the males used may be those carrying known breeding characteristics. The virgin queen honey-bee and the drones are anæsthetized in carbon dioxide under suitable conditions, the semen collected from the males and, by the use of micro seekers and a micro pipette, 5 cu.mm. of semen is injected into the virgin queen bee. In this way complete control is exercised, and any type or strain can be bred. As five generations a year can be obtained, the purity of the strains produced can be recognized in a short time. The film which illustrated the lecture deserved all those adjectives that are often reserved for the commercial cinema.

As usual, one of the most useful features of the meeting was the display of apparatus and teaching devices made by the members, which extended from cotton reels and their uses in physics to "Nuclear Disintegration by Cosmic Rays". The programme for each afternoon consisted of visits to laboratories, institutions and works, all of which had a high scientific value. A reception was held in the County Hall, London, on the evening of January 1.

Nearly nine hundred signed the register of attendance, every part of the British Isles and many countries overseas being represented.

# INDUSTRIAL CHEMICAL EQUIPMENT IN THE UNITED STATES

It is an accepted fact that during the present century the chemical industry has developed at a far greater rate in the United States than it has in Europe. At the beginning of the First World War, Europe was the main centre for the production of chemicals, and the output in the United States was comparatively small; at present it is estimated that two-thirds of the world's supply of synthetic organic chemicals originates in the United States. It is to be noted, however, that Europe still excels in the making of original scientific discoveries; it is in the rapid development of these discoveries to industrial processes that the United States appear to show such marked superiority. Typical examples are detergents, penicillin, streptomycin, many plastics, silicones and chemicals made from petroleum, all of which could be bought in the United States before being made on the eastern side of the Atlantic. The main reason for this is usually ascribed to the very large number of chemical engineers available in the United States for development work, and the very small number trained elsewhere, the ratio being of the order 20 to 1 so far as Great Britain is concerned. During the past few years numerous reports and discussions have emphasized this state of affairs, and many recommendations have been made for training chemical engineers in much larger numbers.

The latest approach to the subject is wider in scope and is a report* entitled "Chemical Apparatus in the U.S.A." made to the Office of European Economic Co-operation by a group of experts who visited a number of American firms. The title is not a happy one, as it fails to convey the expressed object of the mission, which was to investigate so far as possible the reasons for the great development of the American chemical industry. It is obvious that such a task would be beyond the powers of any small body of men in a reasonable time, and consequently the mission has been forced merely to mention some of the causes of development and, after contact with some twenty manufacturing firms, to write more detailed accounts of a few selected operations. The result is bound to be unbalanced, but it is, none the less, very readable. Another difficulty with which the mission had to contend was the use of the term 'Europe' as the antithesis of 'United States'. Europe is still far from being one country, especially where chemical engineering is concerned, so that to state that a process or machine is not commonly used in Europe may be quite accurate where some of the component countries are concerned, but incorrect in other cases. This is particularly noticeable in the case of chemical engineering training, the description of which in Europe can scarcely be taken to apply to Great Britain.

---

* Chemical Apparatus in the U.S.A. Technical Assistance Mission No. 23. Report by a Group of European Experts. Pp. 224. (Paris: O.E.E.C.; London: H.M.S.O., 1952.) 20s. net.

In Part 1 the authors discuss the factors which tend to give American manufacturers an advantage over corresponding firms in Europe. Some of these are as follows: more chemical engineers; superior natural resources; larger home market; stronger internal competition; more vigorous sales methods; greater interest in new processes, products and materials; breaking down of development projects into simple units each dealt with by specialists; greater use of sub-contractors; more standardization, internal and external; greater readiness of firms to publish process details; availability of much empirical information; superior methods of transport and storage; and more instrumentation and automatic control.

It seems probable that the rise of the chemical engineer in the United States was originally due to the requirements of the oil industry. His success in this department led naturally to a call for chemical engineers in other branches of the chemical industries, and the cumulative effect was to produce the present large numbers, many of whom are employed successfully in industries not directly connected with chemistry. It is interesting to note, however, a serious decline in the number of new graduates in the subject, the 1953 figure being estimated at only 36 per cent of that for 1950. This decline is common to other branches of engineering, and a similar trend may be observed in Great Britain.

Many of the advantages listed above are directly dependent on size; thus the larger the connexions of a specialist firm of equipment makers, the more designs can they hold from which to suit a customer and the more can they spend on research. The report emphasizes the attitude of American manufacturers towards new projects, but fails to mention the deterrents which exist, particularly in Great Britain, in the shape of restrictive regulations, insufficient obsolescence allowance, the risk of loss and, in the event of success, the confiscation by taxation of a large percentage or sometimes nearly the whole of any gains. It is surprising that, in these circumstances, development proceeds at all.

Part 2 contains articles on process instrumentation, catalytic processes, distillation and extraction, heat exchange, special equipment, materials of construction, and transport and storage. With the exception of the first, these savour somewhat of the text-book, although an attempt is made to direct attention to plant and methods which are more commonly used in the United States than in Europe. The twenty-six pages devoted to instrumentation give a clear picture of the extent to which automatic control is used in the United States, and thirty-five diagrams indicate the variety of ways in which it can be applied, as well as showing some of the most modern instruments. It is emphasized that automatic control is not merely a device for saving labour, but that the operation of many modern plants would be impossible without it.

The report itself is highly condensed and it is difficult in a brief notice to give an adequate idea of its contents. Few chemical or plant manufacturers, however, bearing in mind the limitations already referred to and reading the subject-matter in an inquiring rather than in a critical manner, will fail to find ideas or suggestions for which they may be grateful.

H. E. WATSON

# ATOMIC ENERGY RESEARCH AT HARWELL

THE main research programmes of the Atomic Energy Research Establishment at Harwell since its inception in 1946 to the end of 1951 are described in a fascinating and connected story of the work and problems of the Establishment, which is the first of its kind to be published*. Some of the information has already appeared in scientific journals, but this new account is presented in a fashion which it is hoped will appeal to the more general reader. The subject, however, is far too technical to be appreciated and understood by any but those who have at least a background knowledge of the physics and chemistry of the atom.

Harwell is only a part, but an important central part, of the British atomic energy project. It has been given two main tasks: to conduct research into all aspects of atomic energy, and to advise the production organization and furnish it with the scientific and technical information that it needs. The atomic pile or nuclear reactor is obviously the primary requirement, and the two Harwell piles—'Gleep', the Graphite Low Energy Experimental Pile, which has been in almost continuous operation since August 15, 1947, and 'Bepo', the British Experimental Pile 0, which was started up on July 3, 1948—have proved invaluable research tools. Full descriptions of these reactors have been published previously, but, for convenience, these are reproduced in an appendix to the volume. Gleep operates at 100 kW., and Bepo, roughly of the same size, operates at 6,000 kW. with air cooling and is mainly concerned with the production of isotopes. These piles have been used to help solve problems in the design of the Windscale production piles, the main function of which is to produce plutonium. This branch of the work is briefly considered in the third of the nine sections into which the volume is divided. Other sections deal with the production and distribution of radioisotopes, perhaps the most widely publicized aspect of the work at Harwell; nuclear reactors and the production of useful power; particle accelerators, their purpose and the various forms in use at Harwell; methods of detection of radiation and of protection of atomic energy workers against damage to their health by exposure to radiation; the fundamental research programme involving chemical, physical and metallurgical investigations (engineering, biological and chemical-engineering work will be described in subsequent publications); and Harwell's extra-mural relations in the two important categories: collaboration through research and development contracts placed with academic, industrial or government laboratories, and exchange of scientific and technological ideas and information through published work, lectures, training schools and conferences.

To the general reader the sections on radioisotopes and on radiation protection will make most appeal. Present deliveries of isotopes, including those of long life which two years ago could be obtained only from the United States, now number eight hundred a month, and an increasing proportion is now made by air transport to many overseas customers. Various applications of radioisotopes in biological, medical and industrial fields are described. The use of cobalt-60 in place of radium is not so well known as

* Harwell: the British Atomic Energy Research Establishment, 1946–1951. Pp. 128+32 plates. (London: H.M.S.O., 1952.) 6s. net.

it should be, and the recent introduction of radioactive sodium for skin-graft operations is an important advance in plastic surgery. The protective measures taken at Harwell give some indication as to how much protection the general public may be able to get in atomic warfare. The instruments devised for the detection of radiation are sensitive and accurate. The frog-suit and helmet that are worn by those who have to come into contact with highly contaminated areas are somewhat frightening, as shown in the illustration given; but nevertheless it is reassuring in that these workers can be thus protected.

In the sections dealing with fundamental aspects, the research and technical worker will find some interesting information. Among the topics discussed are the study of the unusual crystal structure of uranium, which is orthorhombic at room temperature (some more details have recently been published in an article by Dr. H. M. Finniston in *Times Sci. Rev.*, No. 6; winter 1952); the effects of irradiation on the physical properties of crystals and glasses; neutron diffraction; the splitting of carbon into three, and oxygen into four, helium nuclei by high energy X-rays; powder metallurgy, principally of beryllium, zirconium and niobium; and research on ceramics.

It would appear that the compilers of this excellent volume intend to encourage the average student of science to extend his knowledge of nuclear physics, and to assist him in this commendable purpose they provide, in an appendix, a list of books suitable for the non-scientist, another list for students up to honours degree standard, and in addition a list of papers on the generation of useful power from nuclear energy. Perhaps further accounts, similar to "Harwell", to bring the story up to date will aim at particular sets of readers, possibly one account for the general public and another more technical one for the student of nuclear energy in its various aspects.

# THE WORK OF G. F. FITZGERALD

A SPECIAL meeting of the Royal Dublin Society was held on October 30, 1951, to commemorate the centenary of the birth of George Francis FitzGerald (see *Nature*, 168, 930; 1951). A message of greeting was read from the president of the Institution of Electrical Engineers, of the Irish branch of which Prof. FitzGerald was the first chairman. The Physical Society, London, was represented by Prof. K. G. Emeléus, and personal messages of congratulation, received from Sir Edmund Whittaker and from Dr. G. F. C. Searle who remembered FitzGerald personally, were conveyed to the meeting by Prof. F. E. Hackett. Slides and exhibits of some of FitzGerald's models, letters and experiments were shown.

The major part of the meeting was devoted to the reading of five papers dealing with FitzGerald as a man and a scientific worker and with the FitzGerald–Lorentz contraction and its relation to the theory of relativity. The text of these papers, together with two illustrations of FitzGerald as he was in 1878 and 1897, is included in the FitzGerald Memorial Number of the *Scientific Proceedings of the Royal Dublin Society*[*]. In the first paper, Prof. Hackett discusses the character of FitzGerald as revealed by his letters to Heaviside and gives examples of the several brilliant suggestions proposed but not actively pursued by FitzGerald. This is followed by a paper by Prof. H. E. Ives, who, after a brief historical survey of the FitzGerald contraction, derives, using the method of approach of Poincaré's principle of relativity instead of the more usual invariance of the Michelson–Morley experiment, the exact value of the FitzGerald contraction together with the accompanying change of clock frequency perceived by Larmor. Prof. Ives concludes with a brief discussion of the experimental evidence for the contraction and adds some interesting remarks concerning the ether.

Prof. W. H. McCrea discusses some paradoxes of the FitzGerald contraction and their resolution, and Dr. G. J. Whitrow the theories of relativity of Galilean frames with particular reference to E. A. Milne's work. Finally, Prof. J. L. Synge, in a paper entitled "Effects of Acceleration in the Michelson and Morley Experiment", offers an explanation, which he admits may appear fantastic but which is capable of direct experimental test, of D. C. Miller's observations in his 1933 repetition of the Michelson–Morley experiment. The explanation is based on G. H. F. Gardner's theory of the behaviour of a rigid body in accelerated motion. Because of the horizontal position of the interferometer, the original Michelson–Morley experiment is extremely poor as a check on Gardner's theory. An interferometer firmly integrated with the earth and with at least one of the two arms of the interferometer inclined at 45° to the horizontal is required, and such an instrument, Prof. Synge estimates, even with an arm-length of only 20 cm., compared with Miller's 3,000 cm., would give a fringe shift of a full fringe on rotation about a vertical axis. Reference may be added here to an experiment on these lines made by Prof. R. W. Ditchburn and O. S. Heavens (see *Nature*, 170, 705; 1952).

# AMERICAN–ASIAN FLORISTIC RELATIONSHIPS

THE floristic relationship between eastern Asia and eastern North America is the subject of a considerable memoir by Hui-Lin Li (*Trans. Amer. Phil. Soc.*, New Ser., 42, 2, 371; 1952), the subject being one which has interested plant geographers ever since Asa Gray's important paper on the subject in 1840.

While the present work broadly confirms the basic ideas established one hundred years ago, it reviews and revises the data in the light of modern concepts of taxonomy, nomenclature, plant geography and genetics. There is, in fact, a close floristic relationship between eastern Asia and North America, this being particularly marked in the east. Many genera which are common to, and dominant elements in, the two floristic regions have also a wide, general distribution and are therefore less useful in establishing relationships between the two continental regions. But there are many other less widespread genera which are of particular value in this study. Those genera, common to both continents, which are better developed in western than in eastern North America are considered as primary genera of western North America, whence they have spread eastwards into eastern North America and westwards into adjacent parts of north-eastern Asia. Their range is thus more or less continuous.

Leaving aside the many pan-tropical genera, a number of tropical and subtropical genera are known to occur in eastern Asia and in Central America and Mexico, these exemplifying a discontinuous distribution. Temperate and tropical genera which are especially confined to eastern Asia and eastern North America are enumerated. These include trees, shrubs, herbs and vines, some 38 genera being recorded for temperate regions and 19 for tropical regions. These genera are not necessarily of the same geological age and origin, but the evidence indicates that the majority have formed associations with each other and some of them may have been the dominant elements of past floras.

---

[*] *Scientific Proceedings of the Royal Dublin Society*, 26 (N.S.), No. 1: Fitzgerald Memorial Number. Pp. 54+8 plates. (Dublin: Royal Dublin Society, 1952.) 12*s*.

An interesting point is that many of the genera under consideration are of relative antiquity in the phylogenetic scale; they include, for example, ancient genera like *Liriodendron*, *Magnolia* and *Sassafras*, of which reliable fossil records have been obtained. The species of the genera of the two disjunct areas are in most cases sharply defined and, in practically all cases, are different in the two continents, such differentiation being attributed to, or affording evidence of, the long isolation of the two floras. It is in this connexion that later workers have been able to correct the work of Gray and others; for many of the species from the two regions originally considered to be identical have now been demonstrated to be distinct. The truly identical species are found in the colder northern regions and have typically a continuous distribution. Many of these species are very widely distributed, some being typically circumpolar or circumboreal. They comprise plants which are characteristic of the glaciated regions of North America and Europe and are apparently of more recent origin than the disjunctive genera of the temperate region. These are but a few of the points brought out in this unusually interesting survey.

# EXTRA-CELLULAR PHOTOSYNTHETIC REACTIONS IN ENTIRE LEAF MACERATES

By DR. F. C. GERRETSEN

Department of Microbiology, University of Groningen

IN a recent article in *Nature*, Prof. D. Arnon[1] discusses the possibility of extra-cellular photosynthesis. His view that a rather straightforward experimental approach to this problem by using entire leaf macerates does not seem promising, because the stability of the photolytic system in isolated chloroplasts undergoes rapid deterioration, is not shared by me. Though in many cases leaf macerates are indeed useless for the purpose, at least in one case this is not so, namely, in the case of macerized *Avena* leaves. (In more recent studies macerates of young leaves of *Beta vulgaris* also gave satisfactory potential changes on illumination.) Studying the role of manganese in photosynthesis[2], it was proved that filtered cell-free suspensions of crushed *Avena* leaves show a pronounced photo-reactivity for several hours and that an illuminated suspension even retains its reducing power during a dark period of 1–2 hr. following illumination.

Illumination of crude *Avena* chloroplast suspensions generally brings about large and rapid changes of the redox potential as measured with a bright platinum electrode. As the potential of such a complicated and heterogeneous system depends on a number of unknown factors, one has to be very cautious in drawing any definite conclusions from the observed changes; in a number of cases, however, valuable information was acquired concerning the nature of the oxidation-reduction processes occurring during illumination in these suspensions.

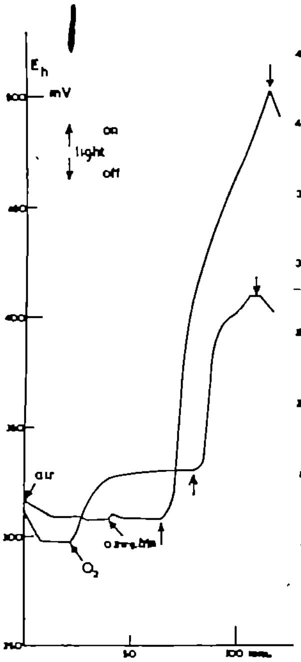

Fig. 1

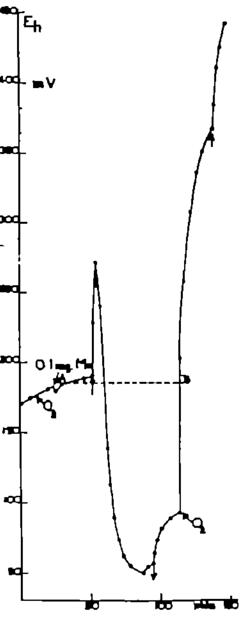

Fig. 2

Fig. 1. Redox potential curves of entire leaf-macerate of two identical leaves of the same oat plant, with and without manganese ions. The addition of manganese has no effect in the dark (↓); on illumination (↑) the potential rapidly rises to 500 mV., indicative of the formation of peroxide. pH 6

Fig. 2. Redox potential curves of leaf macerates. Note (1) that the entire leaf suspension retains its capacity to hydrogenate oxygen in the dark, 45 min. after illumination has been stopped (↓); (2) difference in behaviour at the equipotential points *A* and *B*, which refer to the same macerates in the dark, the only difference being that *B* had been illuminated previously

As may be seen from the accompanying graph (Fig. 1, lower curve) the addition of oxygen to an entire chloroplast suspension in the dark causes the potential to increase insignificantly by about 25 mV., after which it remains constant for about 50 min. When the suspension is illuminated, there is a sudden rise of the potential of more than 150 mV. up to 410 mV.

In the second curve, 0·2 mgm. manganese as manganese sulphate is added in the dark to an analogous suspension, which does not influence the potential. Illuminating this suspension, the potential increases much more and even reaches a maximum of 500 mV. (calculated on the basis of the normal hydrogen electrode).

This experiment, which is representative for a series of experiments of the same nature, shows, in the first place, that the crude chloroplast suspension has retained its photosensitivity for nearly two hours; illumination causes a rapid shift towards a more oxidized state. After the addition of manganese ions the potential rises to a much greater height and reaches 500 mV., which might be indicative of the formation of a peroxide.

The mean maximum value of a series of ten different determinations after the addition of 0·1–0·2 mgm. manganese ions as manganese sulphate to 8 ml. suspension and during illumination was

505 mV., which is 153 mV. higher than in the absence of manganese.

The most plausible explanation of the occurrence of such high potentials in the crude chloroplast suspensions is that during illumination oxygen is photochemically hydrogenated to hydrogen peroxide, which process is accelerated by the manganese ions added to the suspension[2]. Gaffron[3], supporting this view, remarks, "Such an interpretation seems likely, for Mehler[4] in this laboratory has shown that manganese ion has a strong catalytic effect on oxygen uptake by a system, in which $H_2O_2$ is known to be formed in this manner".

The course of another very instructive experiment is shown by Fig. 2. After some oxygen had been introduced into the suspension, manganese sulphate was added in the dark; this did not change the potential appreciably. On illumination, the potential rises very quickly until the oxygen is exhausted; at this moment the potential decreases very rapidly and ultimately reaches a minimum of 52 mV. When the light is turned off, there is generally a slight increase of the potential. Introducing oxygen in the dark into the suspension 20 min. later causes the potential to rise 260 mV. in a few minutes, reaching a height of 365 mV., which increases still further on illumination.

Comparing the equipotential points *A* and *B*, we notice that in both cases oxygen had been recently introduced, manganese ions are present at both points and both are in the dark; the only difference is that *B* had been illuminated 40 min. previously. In this case also these high potentials are indicative of the formation of peroxide, and the capacity of the dark suspension at *B* to hydrogenate oxygen can only be explained by the presence of some strongly reducing compound, which had been formed during illumination and persisted during the dark period. In another case a rise of 180 mV. was observed on the addition of 0·1 mgm. manganese in the dark to a suspension, 115 min. after illumination had been stopped, whereas the addition of the same amount of manganese to a similar unilluminated suspension had no effect.

These experiments are further strong evidence for the existence of a relatively stable intermediary reduction compound, persisting during a dark period following illumination, which has been postulated by van Niel[5] and others[6] and the existence of which had been made plausible by Calvin and Benson[7] with the aid of carbon-14.

In a paper read at the annual meeting of the Society for Experimental Biology at Oxford in April 1949, I showed that when entire *Avena* leaf macerates are illuminated under anaerobic conditions and in absence of carbon dioxide, changes of the redox potential are small, whereas the *p*H remains constant or slowly becomes more acid. After the addition of a small amount of carbon dioxide there is first a small increase of the $E_h$ due to acidification of the suspension, which now on illumination shows rapid decrease of potential of more than 150 mV. within 25 min. (see Fig. 3). At the same time the *p*H becomes more alkaline, whereas in the previous period without carbon dioxide the *p*H became more acid and the macerate did not react on illumination. When the light is turned off, the reverse is observed.

Though it is not suggested that this is an indisputable proof of photosynthesis *in vitro*, it seems likely that the rapid change of the $E_h$ and the alkalinization during illumination after the introduction of carbon dioxide both point to participation of the carbon dioxide in the oxido-reduction reactions of the chloroplast suspension. The amount of carbon dioxide which disappeared during illumination, calculated from the change of the *p*H, is equal to 2–4 per cent of the amount of carbon dioxide used by the same area of intact leaf-surface during normal photosynthesis.

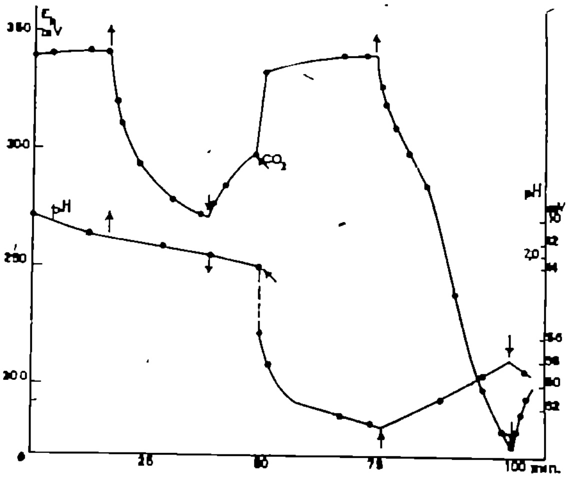

Fig. 3. Influence of the addition of carbon dioxide to an entire leaf macerate on the redox potential and *p*H. Before the addition of carbon dioxide, the $E_h$ soon tends to reach a minimum of about 260 mV. at illumination. The *p*H slowly becomes more acid and does not react on illumination. After the addition of carbon dioxide, the $E_h$ rapidly reaches a much lower value and the *p*H becomes more alkaline on illumination, most probably indicating that carbon dioxide partakes in the photosynthetic reactions

These few examples will serve to show that experiments with entire leaf macerates can procure valuable information on extracellular photosynthetic reactions. This does not, of course, imply that experiments with isolated chloroplasts will not be indispensable to disentangle the complicated photosynthetic apparatus.

# SEPARATION OF NEUTRAL PROTEINS ON ION-EXCHANGE RESINS

By N. K. BOARDMAN and Dr. S. M. PARTRIDGE

Low Temperature Station for Research in Biochemistry and Biophysics, Cambridge

ION-EXCHANGE resins have been used to purify basic proteins of low molecular weight such as lysozyme[1], ribonuclease[2] and cytochrome *c*[3], and a separation of the active substances in a preparation of adrenotropic hormone has recently been reported[4]. We have recently endeavoured to extend the range to neutral proteins such as the hæmoglobins. As in previous work in this field, the resin adopted for these experiments was the monofunctional carboxylic acid cation exchanger 'Amberlite *IRC* 50'.

Paleus and Neilands found that cytochrome *c* could not be eluted from a column of '*IRC* 50' with 0·1 *M* ammonium hydroxide – ammonium acetate buffer below a *p*H of 9·9. Our own experiments, however, have shown that the elution of cytochrome *c* from a column of '*IRC* 50' is very dependent on the cation concentration in the eluting buffer as well as the *p*H. If the cation concentration is greater than 0·22 gm. ions/l., the cytochrome may be eluted at *p*H 7·0. In the work described here, the effect of sodium ion concentration and *p*H of buffer on the adsorption of cytochrome *c* has been studied in detail, and the information gained has been used to predict conditions for the separation of neutral proteins.

Cytochrome *c* was prepared from horse heart muscle by the method of Keilin and Hartree[5], and a chromatographically pure fraction was obtained by adsorbing the preparation on a column of '*IRC* 50' and eluting with sodium phosphate buffer of *p*H 7·0 and sodium ion concentration 0·34 gm. ion/l. This fraction contained 75 per cent of the material put on the column as measured photometrically at 548 mμ but only 55 per cent as measured by the ninhydrin reaction[6]. As impurities in the crude cytochrome preparation, we observed a pale yellow substance[5] which was eluted ahead of the cytochrome band and a red band which remained stationary at the top of the column. This latter band was eluted when the concentration of the buffer was increased and gave the same spectral curve as the main fraction, namely, that for oxidized cytochrome *c*. The main fraction behaved as a single substance when applied to a fresh column of the same resin and could be eluted from it quantitatively. Cytochrome *c* used in subsequent experiments was purified in this manner.

Figs. 1*a* and 1*b* show the effect of *p*H and cation concentration on the elution of cytochrome *c*. The elution volume is unaltered by substituting ammonium for sodium ions and appears to be independent of the nature of the anion. The behaviour of the protein on the resin column, as shown by the continuous line in Fig. 1*a*, is markedly different from that of ampholytes of low molecular weight such as the basic amino-acids. The amino-acid lysine shows a marked maximum adsorption at *p*H 7·3. As the *p*H rises towards its isoelectric point (*p*H 9·7), the lysine is desorbed; and similarly, as the *p*H falls, desorption again takes place due to suppression of the ionization of the resin carboxyl groups. Cytochrome *c* (isoelectric point 10·1) is desorbed in a similar manner to lysine as the *p*H rises from 8 to 10, but is not desorbed under acidic conditions. On the contrary, at *p*H 6–6·5 its elution volume rapidly rises, and under still more acidic conditions the cytochrome band remains stationary at the top of the column.

The broken lines in Fig. 1*a* are plotted from the data of Hale and Reichenberg[7] and Topp and Pepper[8], and show the relationship between the amount of sodium ion taken up by the resin and the *p*H. It will be observed that the rapid rise in the elution volume of cytochrome *c* in sodium buffers occurs over the same *p*H range as the rapid fall in the amount of sodium ion retained by the resin from buffers of comparable concentration. This suggests that the irreversible adsorption of cytochrome *c* that occurs at low *p*H is due to uncharged carboxyl groups on the resin, and that the mechanism of desorption at higher *p*H is concerned with the conversion of the resin to its sodium form. Thus, although electrostatic forces diminish as the *p*H decreases, due to suppression of negative charges on the resin, these forces are replaced by a large increase in the contribution of secondary short-range forces. The increase in short-range forces is most probably due to the concomitant removal of a layer of electrostatically bound water. With substances of high molecular weight, such as the proteins, the contribution of short-range forces towards the net adsorption affinity may be very large, and may be sufficient to account for the apparent irreversibility of adsorption at low *p*H. With amino-acids this contribution will be small, and thus the observed desorption of lysine at low *p*H would be expected.

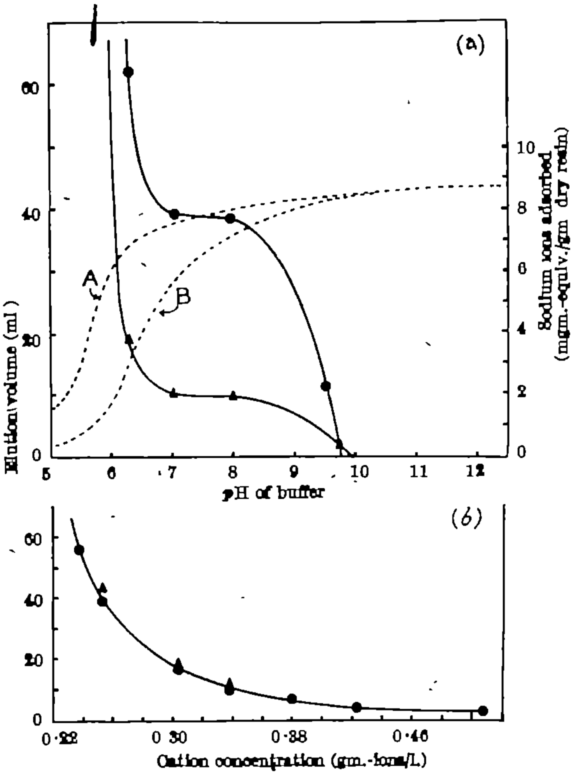

Fig. 1

(*a*) Effect of *p*H on the elution of cytochrome *c* by sodium phosphate buffer. 6·0-mgm. samples chromatographed on columns of 'Amberlite *IRC* 50', 16·0 cm. × 0·9 cm. Rate of flow, 1·0–1·5 ml./hr.; temperature, 25° C. ○, Sodium ions, 0·17 gm. ions/l. △, Sodium ions, 0·34 gm. ions/l. The broken lines show the amount of sodium ion taken up by the resin: *A*, from 1·0 *M* sodium chloride; *B*, from 0·1 sodium chloride

(*b*) Effect of cation concentration on the elution of cytochrome *c*, *p*H 7·0. ○, sodium ions; △, ammonium ions

The interaction of protein and resin may be represented by the following reactions:

$$R^{-}\text{Na}^{+} + \text{H}^{+} \rightleftharpoons R\text{H} + \text{Na}^{+} \quad (1)$$

$$R\text{H} + P^{+} \rightarrow R\text{H} \ldots P^{+} \quad (2)$$

$$R\text{H} \ldots P^{+} + \text{Na}^{+} \rightleftharpoons R^{-}\text{Na}^{+} + P^{+} + \text{H}^{+} \quad (3)$$

$$R^{-}\text{Na}^{+} + P^{+} \rightleftharpoons R^{-}P^{+} + \text{Na}^{+} \quad (4)$$

In these reactions short-range secondary forces are represented by $R\text{H} \ldots P^{+}$ and electrostatic adsorption by $R^{-}P^{+}$. Reaction (2) represents the mechanism due to secondary forces and lies wholly to the right; (3) shows the desorption of the protein in the presence of sodium ions; and (4) shows the reversible adsorption of the protein due to electrostatic forces.

The electrostatic attraction between protein and resin will depend on the net charge on the protein molecule and, to a lesser extent, on the distribution of that charge. The secondary forces will be influenced by the chain-length of the protein molecule, its configuration, and also on the nature of the side-chains. It should thus be possible to separate proteins of the same net charge but with different molecular configurations, or proteins of the same molecular weight but with different net charges. An example of the first type of separation is that of lysozyme and cytochrome *c*, which are proteins with approximately the same isoelectric point (10·5, 10·1) and molecular weight (15,000): the elution volumes are very different, and with a column of 5 cm. × 0·9 cm., cytochrome is eluted with sodium phosphate buffer in 3·3 ml. and lysozyme in 26 ml. As an example of the second type, a successful separation has been obtained with bovine carboxyhæmoglobin and sheep fœtal carboxyhæmoglobin, samples of which were kindly prepared by Dr. G. S. Adair.

Separation of the hæmoglobins presents two major difficulties. First, the proteins are readily denatured and at their isoelectric points slowly form precipitates even at 0° C. Secondly, the proteins are isoelectric near neutrality and thus the flat section of the adsorption – *p*H curve between *p*H 7 and *p*H 9 found with cytochrome *c* is absent. The isoelectric points of bovine carboxyhæmoglobin and sheep fœtal carboxyhæmoglobin are respectively 7·3 and 6·7 at 0° C. in phosphate buffer of ionic strength 0·02 [9]; but in the *M* citrate buffer used for the chromatographic experiments, their isoelectric points lie between 4 and 5 [10]. Thus in citrate buffer at *p*H 6, both proteins have a net negative charge, and neither is adsorbed by the resin. On the other hand, as is shown in Fig. 1*a*, at *p*H 5 the carboxylic groups of the resin are almost wholly undissociated, and adsorption of the hæmoglobins is complete and irreversible. The elution volume – *p*H data of the hæmoglobins may thus be represented by a family of steep curves falling rapidly from very high values to zero in the narrow range *p*H 5–6, the curves for the more acidic proteins being displaced to the left of those for proteins with higher isoelectric points.

Owing to the extreme steepness of the curves, chromatographic behaviour is sharply dependent upon the *p*H and cation concentration of the buffers, and these must be accurately controlled. The best separation of the two hæmoglobins investigated here was obtained at *p*H 5·81 (sodium ion concentration 0·34), and under these conditions sheep fœtal carboxyhæmoglobin was unabsorbed ($R_F = 1$) and the bovine carboxyhæmoglobin had a value for $R_F$ of 0·7.

Fig. 2*b* shows the chromatogram obtained from sheep fœtal hæmoglobin in citrate buffer of *p*H 5·8 at 25° C., using a column of finely ground '*IRC* 50', 5·0 cm. × 0·9 cm. The effluent from the column was collected in 0·2-ml. fractions and the hæmoglobin content of each fraction determined photometrically at 550 mμ. It was observed that as the hæmoglobin band progressed down the column it left behind a light deposit of coloured protein which appeared to be uniformly spread over the whole column. The carboxyhæmoglobin in the band was nevertheless eluted as a symmetrical peak without tailing. It was concluded that the material remaining on the column was probably denatured hæmoglobin (or represented some stage in the denaturation of the protein). It was found that the denatured protein could be eluted with concentrated sodium citrate buffer of *p*H 6·5 (sodium ion concentration 3·2), and peak *C* in Fig. 2*b* is the elution curve formed by this material.

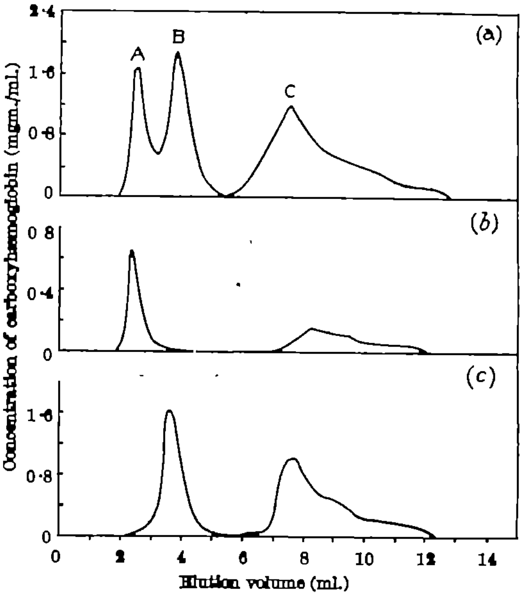

Fig. 2. Chromatograms of carboxyhæmoglobin using a column of '*IRC* 50', 5·0 cm. × 0·9 cm. Rate of flow, 0·5 ml./hr.; temperature, 25° C. Buffer: citrate *p*H 5·81, sodium ion concentration 0·34, changed to citrate *p*H 6·5, sodium concentration 3·2 after 1·2 ml.
(*a*) 5·7 mgm. of a mixture containing sheep fœtal carboxyhæmoglobin and bovine carboxyhæmoglobin. (*b*) 2·5 mgm. sheep fœtal carboxyhæmoglobin. (*c*) 3·1 mgm. bovine carboxyhæmoglobin.

The chromatogram of bovine carboxyhæmoglobin is shown in Fig. 2*c*, and it will be observed that this protein also shows a second peak on changing the buffer to one of higher concentration and *p*H. The two carboxyhæmoglobins were then mixed and the elution carried out under the same conditions. Fig. 2*a* shows that the two proteins separated as symmetrical peaks (labelled *A* and *B*) and that the denatured material from both appeared as a third peak (*C*). Samples of pure protein obtained from peaks *A* and *B* appeared to contain no denatured material.

While the separation of the two hæmoglobins described above is satisfactory for some purposes, and could no doubt be improved somewhat by the use of a rather longer column, the yields of the pure components were low. It appears probable that, if the material in peak *C* has indeed been denatured by passage down the column, yields could be improved by working at lower temperatures. A study of the nature of the processes leading to changes in the protein on the surface of the resin is in progress, in the hope that extension of the procedure to the separation of other protein systems will be possible.

We wish to thank Dr. G. S. Adair for many helpful discussions during the course of this work. One of us (N. K. B.) is the holder of a Dafydd Lewis Trust Scholarship. The work forms part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

## Action of Antibiotics on Avian Tubercle Bacilli studied with the Electron Microscope

THE method described by Brieger and Cosslett[1] of growing tubercle bacilli on the 'Formvar' film of a stainless steel electron microscope grid has been modified for use with liquid media. In this form the method has been found suitable for a study of the action of antibiotics upon growing tubercle bacilli. In order to prevent the fluid medium contaminating the inoculated surfaces, the grids are placed in contact with filter paper which rests on a cotton-wool support in a small dish 5 cm. in diameter and 2 cm. deep. The cotton-wool is kept moist by being thoroughly soaked in the medium. One dish can take up to twenty grids. The grids are inoculated with a drop of bacillary suspension using a fine platinum loop. If the drop does not stay on the surface of the grid, it is assumed that the holes in the 'Formvar' film are too large and the grid is discarded. The grids on which the drops remain are considered to be inoculated with similar numbers of bacilli. The dishes are incubated at 37·5° C. and grids removed at various intervals for inspection. Each grid is floated on sterile distilled water to remove any medium adhering to the lower surface, fixed by floating on 5 per cent formalin for 30 min., and washed again to remove any excess fixative. Throughout the procedure care is taken that the inoculated surface of the grid remains undisturbed. This is an essential condition for the study of variations in growth-rate.

A preliminary experiment was carried out to compare growth on the grids with growth directly on the medium. Grids inoculated with avian bacilli were placed on a Löwenstein plate and examined daily. At the same time, uninoculated grids were laid face downwards on the growth on a Lowenstein plate and impression prints taken on the 'Formvar' film. The comparison showed that the diffusion of the medium through the 'Formvar' film does not impair growth to any large extent. In fact, if inoculated grids are placed in dishes with Dubos medium, growth is usually so rapid that the squares of the grid are overgrown in two to three days even if the inoculation is made with a dilute suspension. With Dubos medium it is advisable to use small inocula and to examine the grids with a dry phase-contrast objective (× 40) before investigation in the electron microscope. Phase-contrast observation of grids can also be applied to the study of problems such as viability and growth-rate, especially the growth-rate in small inocula. Unfortunately, photographic recordings do not give very satisfactory results because the presence of the grid bars makes good phase-contrast difficult. However, some comparison can be made of the morphology and internal structure of the bacilli located in one square with phase-contrast and electron microscopy. Grids can also be stained in the normal way by carbol-fuchsin, after the examination by electron microscopy is completed. It is remarkable that the bacilli retain acid-fastness after exposure to the electron beam.

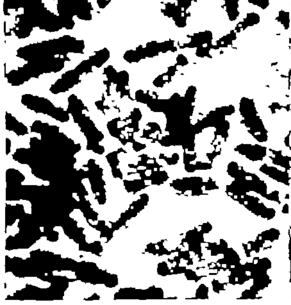

Fig. 1

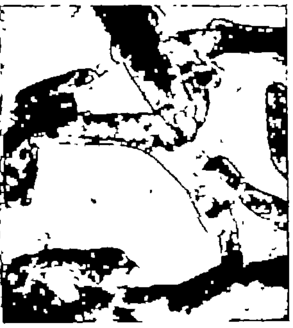

Fig. 2

Fig. 1. Growth on normal Dubos medium. 3 days. Shadowed. × 6,200

Fig. 2. Growth on Dubos medium containing 100 μgm. of streptomycin per ml. 3 days. Shadowed. × 6,200

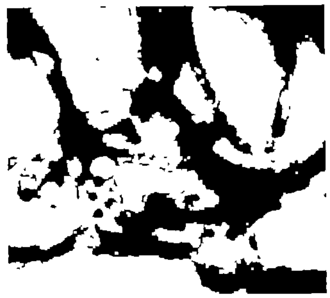

Fig. 3. Growth on Dubos medium containing 10 μgm. of streptomycin per ml. Mycelial strain. 5 days. Unshadowed. × 6,200

To study the action of streptomycin and *iso*nicotinic acid hydrazide ('Ditubin', Schering) two sets of dishes were prepared in which the Dubos medium contained 0, 10, 20 and 100 μgm. of antibiotic per ml.

Under normal conditions, the short bipolar rods of the inoculum elongate up to seven times their original length in 24 hr. During this time, internal structure becomes apparent and shows that the filaments consist of a row of intracellular units and have two dense polar bodies. After three days the uniform bipolar filaments have broken down into individual rods (Fig. 1). The cultures containing streptomycin grow more slowly; the filaments initially formed differ from the normal ones in being much broader and showing less definite internal structure (Fig. 2). The bipolar densities which are still present in most filaments often increase in size and become distorted.

The mycelial tendencies present in some strains are encouraged by small doses of streptomycin, which also cause a broadening of the branches and an irregular arrangement of the dense bodies (Fig. 3). Higher concentrations of streptomycin (100 μgm. per ml.) arrest growth in the mycelial stage, and after seven days of incubation the filaments become very broad and some disintegrated mycelial branches are regularly seen.

In comparison, *iso*nicotinic acid hydrazide produces very different results. A dose of 10 μgm. per ml. has very little visible effect on the growth pattern. With doses of 20 μgm. per ml. and more, the rods of the inoculum do not elongate at first and seem to shrivel, lose their transparency, and appear as dense oval bodies with tapering ends. The further development depends upon the dose. With a dose of 20 μgm. per ml. normal filaments develop within three days side by side with the tapering rods (Fig. 4*a*). After

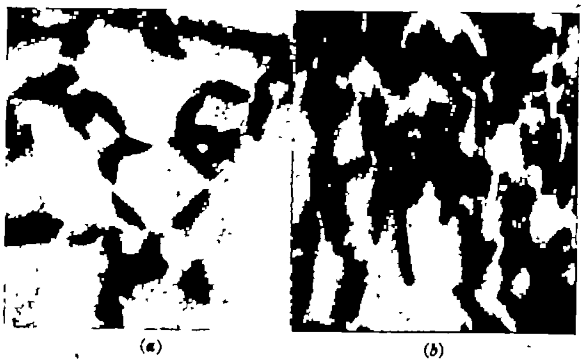

Fig. 4. Growth on Dubos medium containing 20 μgm. of *iso*nicotinic acid hydrazide per ml. (*a*) 3 days. Shadowed. × 6,200; (*b*) 7 days. Shadowed. × 6,400

seven days the cultures seem to recover partially and a mass of filaments covers some squares of the grid (Fig. 4*b*). At higher concentrations of *iso*nicotinic acid hydrazide (100 μgm. per ml.) recovery does not begin until the seventh day of incubation and growth is greatly retarded.

Our observations only refer to the action of antibiotics on an avian strain which had lost much of its virulence during subculture. The results suggest that the technique described may be of value in assessing the action of antibiotics at a very early stage of development. They also show that streptomycin and *iso*nicotinic acid hydrazide attack the bacillus in different ways and cause different morphological changes. The initial inhibition by *iso*nicotinic acid hydrazide and the more delayed action of streptomycin suggest that a combination of the two antibiotics should give promising results. Clinicians have already used combined treatment with good effect. The method should also be useful in studying the genetical aspects of resistance to these substances.

We wish to thank Mr. H. Pearson for invaluable assistance in taking the electron micrographs.

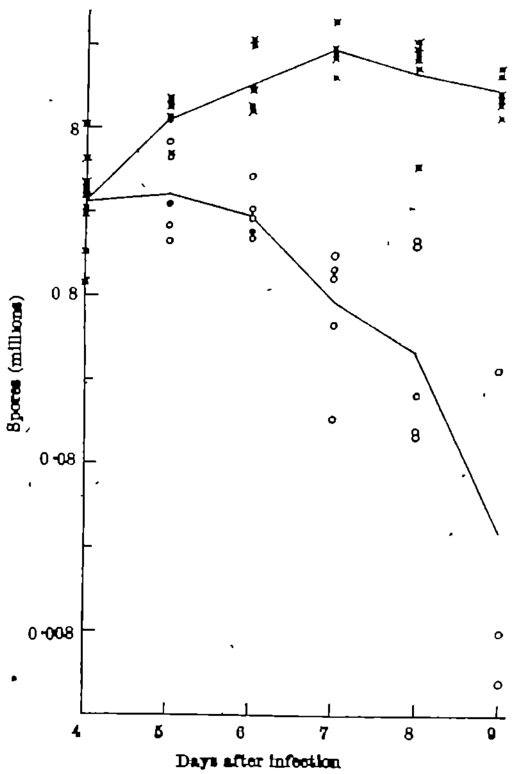
## Effect of Fumagillin upon *Nosema apis* (Zander)

A preliminary report by Katznelson and Jamieson[1] on the effect of the antibiotic fumagillin (derived from an *Aspergillus* culture designated *H*–3 [2]) upon the infection of the adult honey bee by the microsporidian *Nosema apis* indicated promising results. They suggested that the action of the drug was prophylactic in nature, killing the infective amœboid phase which is released from the spore into the ventricular lumen prior to its entry into the epithelial cells. This view was probably suggested by the results of McCowen *et al.*[3], which showed a depressant action of the drug upon the growth of bacteria-free cultures of *Endamœba hystolytica*.

I have fed measured numbers of spores of *Nosema apis* to individual bees and watched the progress of infection under various conditions of treatment by sampling bees daily and counting the ventricular content of spores by means of a hæmocytometer.



Group of individually infected bees (fed 1,000,000 spores each) divided four days after infection. One group (O—O—) fed freely on 6 mgm. fumagillin per 100 ml. of syrup; the other group (×—×—) continued on plain syrup.
6 mgm./100 ml. is a heavy dosage of drug. The effect becomes significantly less when about 1 mgm./100 ml. or less is fed

This technique has shown that the infection is most probably arrested or destroyed during its intracellular phase. If, for example, the infection was allowed to become well advanced and then the drug was fed in syrup, a practically instantaneous decline in infection took place (see graph). Also, bees fed with the drug during and after infection showed no greater decline in infection than those bees which were put on the drug two days after infection, by which time the intracellular phase of infection is well established and no amœboid forms remain within the ventricular lumen.

Sections of the ventriculus from recovering bees showed that spores became more restricted to those cells farthest away from the regenerative crypts or nidi. This suggests that the early vegetative forms of the parasite have been killed, or arrested in their development and re-infection of adjacent cells. The natural regeneration of cells from the crypts replaces those cells containing the later developed forms of the parasite.

Examination of sections and fresh material shows no histological difference between the renewed epithelium of the recovering bee and the epithelium of the healthy bee. The death-rate of treated bees was no different from that of healthy bees. Thus an intracellular protozoan parasite was destroyed in a striking fashion without any apparent damage to the structure and physiology of the host. However, relapses occurred even after the cessation of seventeen-day treatments; infection persists at the anterior end of the ventriculus, where the œsophageal invagination shields the epithelium.

Further experiments of this nature and with colonies of infected bees are in progress and the results will be published later. Thanks are due to the Upjohn Company of New York for supplies of fumagillin.

## Heat Exchanges of a Muscle Model

TENDONS immersed in a solution of mercury – potassium iodide contract; if held at constant length they exert tension, there being a reversible relation between tension and concentration of the reagent[1]. This system has been proposed as a model of the molecular mechanism of muscular contraction[2], and may be taken as typical of such models[3]. The reagent appears to act as a 'plasticizer', weakening attractions between protein molecules, and leaving them free to curl up under the influence of thermal agitation.

To demonstrate the energy relations of the system, a continuously acting machine was constructed, based on one described by Wiegand[4]. This consisted of a wheel with a heavy brass rim and twenty-four spokes made from tendons. The wheel was suspended in a narrow trough which was filled to the level of the axle with a concentrated (2 *M*) solution of mercury – potassium iodide, and above that with a very dilute solution. The lower spokes, which are immersed in the concentrated solution, contract, stretching the upper spokes and bringing the wheel out of balance so that it rotates half a turn. This brings the contracted spokes up into the dilute layer, in which they give up reagent and are extended in their turn by the contraction of the lower spokes. A light ratchet ensures that rotation is always in the same sense. The time for a complete rotation was about twenty minutes.

Over a complete cycle, the condition of the working substance, the spokes, is unchanged, and energy can only be derived from mixing of the solution. The heat of dilution of the mercury – potassium iodide solution was found to be negative, the addition of 50 ml. of a 2 *M* solution to an equal volume of water absorbing about 117 calories. This comparatively large absorption of heat indicates that dilution is accompanied by a net increase in potential energy, so that the only possible source of energy for mechanical work is the increase in the entropy of the solution on mixing.

The energy exchanges were followed in more detail by using shredded collagen (standard hide powder) instead of whole tendons; this permitted the use of large quantities, so that changes in temperature could be followed with a Beckmann thermometer. The heat of reaction of a molar solution of mercury – potassium iodide with swollen hide powder was found to be 1 cal./gm. dry weight, a low value which agrees with the observation that the reaction can be reversed by tension. By comparing natural hide powder with gelatin and with hide powder 'melted' by previous heating, a figure of 4 cal./gm. was obtained for the 'latent heat of fusion'. Both these values are the means of six determinations and are probably reliable to within about 1·5 cal./gm. The value for the latent heat of fusion is a minimum, but is perhaps nearer the mark than the figure of 16·8 cal./gm. found for tendon by Wöhlisch and de Rochement[5], which is based on a false estimate of the water content. Energy available from changes in crystalline arrangement thus seems to be small. The quantity of reagent absorbed was estimated by measuring the density of an *M*/4 solution of mercury – potassium iodide before and after allowing it to react with natural hide powder. From these measurements it appeared that, under the conditions used, about 3 gm. of mercury – potassium iodide are absorbed by 1 gm. dry weight of hide powder. This corresponds to 1 molecule of mercury – potassium iodide to 170 units of protein, or about 1 mol. per amino-acid.

We may now compare the model with Nature. It has been suggested that muscle operates on a similar cycle, with actomyosin as working substance and adenosine triphosphate as plasticizer, removal of plasticizer during the extension phase being by chemical decomposition rather than by elution. The first objection to this simple view concerns concentrations of reagent and amounts adsorbed. Adenosine triphosphate will cause contraction of extruded actomyosin filaments at concentrations[6] of the order of $10^{-6}$ *M*, and the amount adsorbed during contraction is of the order of 1 mol. per 100,000 units[7]. The least concentration of mercury – potassium iodide required to bring tendons to their 'fibre melting point' is about 0·2 *M*, at which the uptake is about 1 mol. per 170 units. No simple plasticizer could function at such dilutions as adenosine triphosphate does, but the mechanism in muscle is presumably an indirect one, involving some critical change of shape in the myosin by which it is rendered incapable of fitting on to the actin. A second difficulty is that, according to Weber[6], adenosine triphosphate does not bring about contraction of actomyosin filaments unless it is broken down at the same time; a filament of which the enzymatic activity has been abolished merely becomes plastic. Weber contrasts the activity of adenosine triphosphate in causing contraction with its effect as a plasticizer, but it appears from the model that the two differ only in degree, as tendon can be brought to a plastic state by the action of a concentration of mercury – potassium iodide just too low to cause contraction. The effect of the small amount of adenosine triphosphate adsorbed at any one time may be intensified by repeating the cycle, successive segments of the same molecule extending one another in the same way that one spoke extends another in the model. The rate of production of energy would then depend on the frequency of repetition of the cycle and on the amount of adsorbed plasticizer, which is in turn a function of the load.

## A Coagulase-destroying Factor produced by Variants of *Staphylococcus aureus*

It has recently been shown[1] that rough variants of *Staphylococcus aureus* give high, and smooth variants low, yields of coagulase. The present communication shows that certain smooth variants produce a factor capable of destroying coagulase.

It was noticed that some colonies of the smooth variants were surrounded, on 'chocolate' agar, by a zone of discoloration and transparency. Cultures made from such colonies were more proteolytic (speed of liquefaction of gelatin, peptonization of milk), and yielded less coagulase than smooth variants with no action on chocolate agar. Some, in fact, did not clot plasma in 24–48 hr.; it is important, however, to mention that these were unstable and sooner or later gave rise to coagulase-positive cultures. From both the weakly positive and the apparently coagulase-negative, proteolytic variants a coagulase-destroying factor was isolated.

Many colonies showing a maximum zone of discoloration on chocolate agar were selected; each colony was suspended in 2 ml. of saline and inoculated on to a large agar slope in an 8-oz. flat bottle. After 18 hr. incubation at 37° C. each slope was washed with 4 ml. of meat-extract broth (*p*H 7·2); the suspensions were spun, the sediments discarded and the supernatants tested for plasma-clotting power. Those failing to cause clot in 24 hr. or with long clotting times (more than 6 hr.) generally contained the coagulase-destroying factor.

The coagulase-destroying activity of the supernatants was estimated in the following manner: mixtures of cell-free, heated coagulase were made with: (*a*) the supernatant, (*b*) the autoclaved supernatant and (*c*) meat-extract broth of a *p*H identical with that of the supernatant. All reagents contained 0·1 per cent merthiolate. Destruction of coagulase was revealed by a progressive increase of clotting time and decrease of titre of the mixture of coagulase with non-autoclaved supernatant (*a*); no destruction of coagulase was observed in the controls (*b*) and (*c*).

Variants showing the presence of the coagulase-destroying factor were found in all of ten strains examined, five strains giving extremely active variants. Thus the clotting power of a coagulase of a titre of 1 : 8,000 and a clotting time of 2 min. was completely abolished by incubation for 24 hr. with an equal volume of a very active supernatant. With potent preparations of the coagulase-destroying factor the destruction of coagulase at 37° C. became apparent 15–30 min. after mixing and progressed for 24–40 hr. The activity of the coagulase-destroying factor was most marked at a *p*H of 6·8–7·2; the activity was not strain specific. Cell-free coagulase-destroying factor was obtained by filtration through sintered glass and could be concentrated by cold (4° C.) precipitation with ten volumes of ethanol. The activity of the crude preparation was partly lost on heating for 10 min. at 70° C. and abolished by boiling for 30 min.; the ethanol-precipitated preparation was more heat-sensitive. The coagulase-destroying factor was inhibited by whole serum (man and horse), by serum globulins and by egg white.

Purely as a working hypothesis, it is assumed that the coagulase-destroying factor is a proteolytic enzyme. It is thought that along with the rough ⟷ smooth variation in *Staphylococcus aureus* the occurrence of this factor may explain the irregularity of coagulase production *in vitro* observed by many workers. It seems also logical to believe that the coagulase-destroying factor is at least partly responsible for the low coagulase yields of smooth variants of this organism.

## Noise from Aircraft at Supersonic Speeds

T. GOLD, in *Nature* of November 8[1], has directed attention to the need for an explanation of the bangs that have been heard when aircraft in the vicinity have exceeded the speed of sound.

Gold develops his argument sufficiently far as to indicate when bangs may be expected. Briefly, an observer will experience a bang from every occasion on which the aircraft is travelling towards him at the speed of sound. This happens whenever $-\mathrm{d}r/\mathrm{d}t = c$, where $r$ is the scalar distance of the aircraft from the observer, and $c$ is the speed of sound. We see at once that triple and quadruple bangs will occur if there are three or four occasions respectively on which the aircraft is travelling towards the observer at sonic speed. Moreover, the aircraft itself does not have to pass through sonic speed more than twice to cause such multiple bangs: they can be caused by changes of course.

The occurrence of bangs having been explained, one must next consider their intensity. This will depend primarily upon $\mathrm{d}^2r/\mathrm{d}t^2$, varying inversely as the square root of this quantity if $\mathrm{d}^3r/\mathrm{d}t^3$ and higher derivatives can be neglected. It should be noted that $\mathrm{d}^2r/\mathrm{d}t^2$ is not the acceleration of the aircraft away from the observer, which is $\mathrm{d}^2r/\mathrm{d}t^2 - r(\mathrm{d}\theta/\mathrm{d}t)^2$. For $\mathrm{d}^2r/\mathrm{d}t^2$ small, the intensity will depend also upon $\mathrm{d}^3r/\mathrm{d}t^3$. A flight path such that $\mathrm{d}r/\mathrm{d}t$ is constant and equal to $-c$ is of interest, as $\mathrm{d}^2r/\mathrm{d}t^2$, $\mathrm{d}^3r/\mathrm{d}t^3$ and all higher derivatives are zero, and a bang of enhanced intensity would be expected. Such a flight path is the equiangular spiral of angle equal to the Mach angle, $r = r_0 \exp\{-\theta/\sqrt{(M^2 - 1)}\}$, where $M$ is the Mach number. It degenerates for a Mach number of unity into a straight line, and for a Mach number of infinity into a circle. The former is of interest in indicating that disturbances of enhanced intensity are to be expected from periods of steady flight at a Mach number of unity, although they will be localized, and will be experienced only by observers in the direct line of flight.

The final point that needs clarification is the cause of the bangs. Three possible sources of the disturbances can be put forward, the disturbances in all cases being propagated in the same manner, as outlined by Gold. First, there are the aerodynamic disturbances that would result from flight through an inviscid fluid: these will depend upon the size and shape of the aircraft. Secondly, there are the aerodynamic disturbances due to the turbulence created by the boundary layers, by regions of flow separation and by the wake. Finally, there are the acoustic disturbances which arise from the fact that the aircraft, through the medium of its engines, is a source of noise. Simple estimates show that the enhancement of the noise of the aircraft in a typical case falls very far short of the intensity of the pressure disturbance associated with the bang (about 1 lb./ft.$^2$). Equally, although it is more difficult to show, it is not expected that the enhancement of the disturbances due to turbulence could be sufficient to explain the intensity of the bangs. On the other hand, calculations have been made of the disturbances to be expected from flight through an inviscid fluid, and these yield pressure disturbances that are of the same order as those that have been experienced.

Thus far we have explained the occurrence of the bangs, and the intensity of the peak pressure disturbance to be expected. What still needs clarification is the acoustic 'character' of the bang. In particular, do the disturbances due to engine noise and due to turbulence make a significant contribution to what one actually hears ?

I am indebted to the Chief Scientist, Ministry of Supply, for permission to publish this communication, but the views expressed are my own.

C. H. E. WARREN

Royal Aircraft Establishment,
Farnborough, Hants.
Nov. 19.

---

[1] *Nature*, 170, 808 (1952).

THE impression exists that the double bang made by supersonic flight is mysterious. It would be well if those who support this view would bring forward the arguments that show that the exact and straightforward account of the bangs given by T. Gold[1] is wrong. The following circumstances have made the subject seem mysterious ; but, in fact, none of them is a real objection to the straightforward account.

(*a*) At the recent Farnborough display, the black *D.H.* 110 aircraft gave a triple bang on at least one occasion. But we should in general expect multiple bangs if an aircraft were to change course slightly in its supersonic flight, for then there would be two solutions of the equation $-dr/dt = c$, for each straight portion of the aircraft's path, where $r$ is the scalar distance between aircraft and observer. When three bangs are heard, it is likely that there are really four, of which two happen to coincide. It must be remembered that these bangs are so close as scarcely to be heard separately.

(*b*) The bangs are often said to be produced as the aircraft 'pierces the sound barrier' at either end of its supersonic flight. This is inconsistent with Gold's account, according to which at every given supersonic speed there is a direction making a definite angle with the direction of flight along which the bang will be propagated. Now the first account cannot be correct, because it means that the very loud bang heard at all points on the ground will have been produced at one point in the track of the aircraft. Such a dissipation of energy would be of an altogether greater order of magnitude than that at other points, and the aircraft could not accelerate to greater speeds.

(*c*) The objection that shock waves and sound waves are different in nature is not relevant to this discussion, because we need consider only regions outside a certain closed surface surrounding the aircraft, at all points of which the particle displacement due to sound or shock waves is small compared with their wave-length. Yet this closed surface can be effectively at a point as far as listeners on the ground are concerned.

E. W. BASTIN

---

[1] *Nature*, 170, 808 (1952).

THE acoustic phenomena accompanying the dive of an aircraft to attain supersonic speed appear to be adequately explained by the Huyghens wavelet construction. The case of a body moving at a uniform supersonic speed $V$ in a straight path, in a uniform atmosphere, is well known. Circular wavelets, expanding with the velocity of sound $c$, are centred on successive positions of the body at chosen time intervals. The envelope of the wavelets representing a shock wave front is a cone with the line of flight as axis and half-angle $\alpha$ given by

$$\sin \alpha = c/V = 1/M,$$

where $M$ is the Mach number.

In the case of a body moving in a uniform atmosphere, in a straight path, at a speed which increases and then decreases through the speed of sound, the shock wave departs radically from the single conical surface and becomes a meniscus symmetrical about the line of flight, with two surfaces. In the example shown in Fig. 1, the duration of supersonic flight is 16 sec. and the Mach numbers are shown at the positions of the body at second intervals.

In the case of a body moving in a uniform atmosphere, at a uniform speed, in a curved path, the shock wave becomes a distorted meniscus. The section in the plane of the flight path is similar in general outline to that shown in Fig. 2.

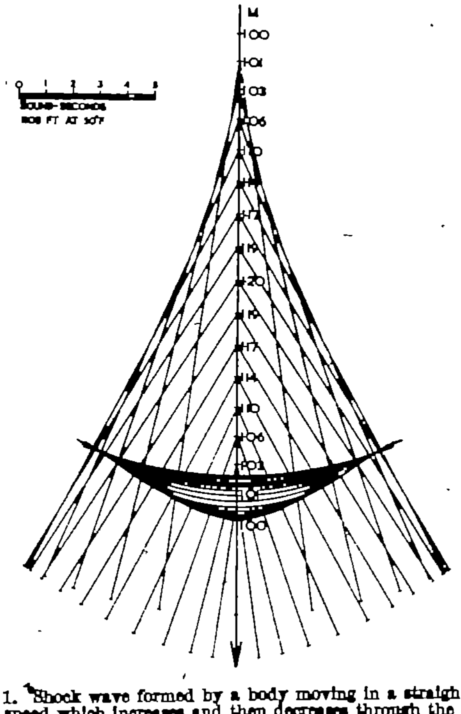

Fig. 1. Shock wave formed by a body moving in a straight line at a speed which increases and then decreases through the speed of sound

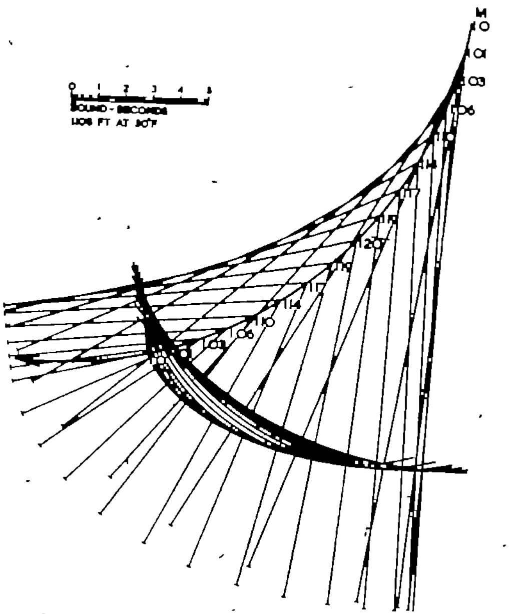

Fig. 2. Shock wave formed by a body moving in a circular path at a speed which increases and then decreases through the speed of sound

In the case of a body moving in a uniform atmosphere, in a curved path, at a speed which increases and then decreases through the speed of sound, the shock wave is again a distorted meniscus. The section in the plane of the flight path is represented in Fig. 2 for the particular case in which the flight path is the arc of a vertical circle with radius 15 sound-seconds and the duration of supersonic flight is 16 sec., the assumed Mach numbers at second intervals during this period being shown against the positions of the body. Sound rays are drawn from the point of origin of each wavelet perpendicular to the shock wave front. To do this the ray is drawn at an angle $\alpha$ given by $\sin \alpha = 1/M$, to the tangent to the circular flight path at the point of origin of the particular wavelet, $M$ being the Mach number at that point. The separation of the rays is a measure of the intensity of the shock wave; the closer the rays for a given length of flight path the greater the intensity.

The outstanding features of the shock wave are as follows. (1) The shock wave has two surfaces, the forward one being due to the lower part of the flight path and the rear one to the upper part of the path. The time interval between the two surfaces varies from zero at the outer edge of the shock wave to a maximum at or near the middle of it. The maximum interval and also the extent of the shock wave are greater the greater the maximum Mach number attained, the smaller the acceleration to that Mach number from $M = 1$, and the flatter the curve of the flight path. Uniform supersonic speed in a straight path is a particular case in which acceleration is zero and the interval is infinite. In the example of Fig. 2, for which the radius of curvature of the flight path is 15 sound-seconds, the duration of supersonic flight is 16 sec. and maximum Mach number is 1·2, the maximum interval is about 1·2 sec.

(2) The shock wave is most intense near its outer edge. The intensity on the inside of the curve of the dive, near the plane of the curve, is greater than on the outside of the curve and is maintained to greater distances after the Mach number has fallen below 1 because the divergence of the rays is comparatively small. Intensity is increased by increasing the acceleration to maximum Mach number from $M = 1$ and by diving in a path of smaller radius of curvature.

The assumptions of a uniform atmosphere and a dive in a vertical circular arc are simplifications of the actual case of an aircraft diving to attain supersonic speed, but the features listed above should be fairly representative of the acoustic effects to be expected.

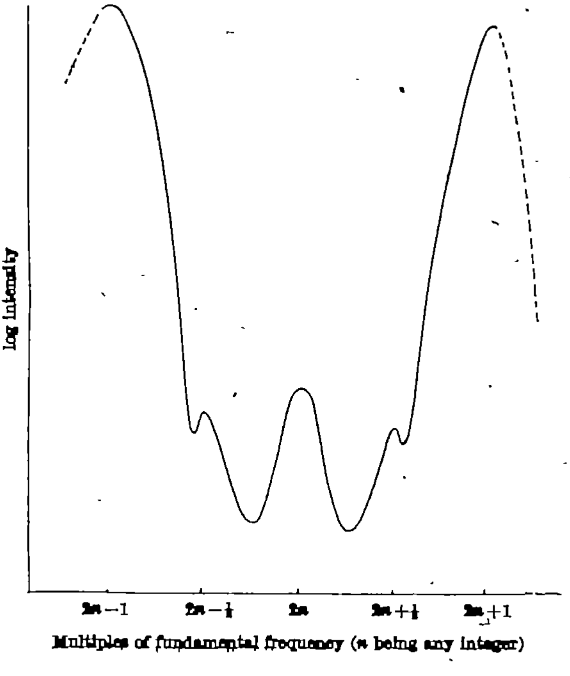
## Piezo-electric Oscillations of Quartz Plates at Even and Half-odd Harmonics

It is well known that a piezo-electric quartz plate can be excited into strong oscillations at its fundamental frequency, mainly determined by its thickness, or at any of its odd multiples, the even multiples being ruled out on theoretical considerations[1]. Parthasarathy[2] first observed that a quartz plate can vibrate at its 5/2 and 7/2 harmonics. Afterwards, Parthasarathy, Pande and Pancholy[3] showed that an X-cut quartz plate could also be made to oscillate, though with a lower intensity, at its even harmonics and such frequencies as ½, 3/2, 5/2, etc., of its fundamentals. This observation was later confirmed by Tsien and Chu[4] and Özdogan[5]. The former also reported that, besides the even and half of odd multiples of the fundamental frequency, the plate would oscillate continuously, though with less intensity, at any intermediate frequency.

It has been suggested[1,4] that this effect might be due to one or more of the following causes: (*a*) twinning or other defect in the quartz plate; (*b*) inhomogeneous electric field; (*c*) uneven plating; (*d*) feed-back to the oscillator. Experiments were



recently undertaken with the view of eliminating these possibilities. A number of quartz plates of different dimensions, obtained from well-known American manufacturers of frequency-control crystals, were plated fairly uniformly with silver, aluminium and copper by different methods such as electrochemical deposition, metal evaporation in vacuum, electroplating, etc. These plates were excited by the output of a master-oscillator power-amplifier with a buffer amplifier in between the oscillator and the crystal. The crystal was put in a liquid medium and the diffraction pattern obtained by the usual Debye–Sears method. It was noticed that the crystal could be made to oscillate at any frequency, though the intensities varied at different frequencies. The relative intensities of the diffraction lines revealed that, for the same radio-frequency feed, the crystals oscillated vigorously at their odd harmonics and less vigorously at the even and half of odd multiples. The intensities of the diffraction lines showed peaks in these regions. In going from one odd harmonic to another, the amplitude of oscillations as indicated by the diffraction lines undergoes variations as shown in the accompanying graph.

The results confirm the earlier observations that a piezo-electric quartz plate has preferred modes of oscillation at the even and half of odd multiples of its fundamental frequency in addition to the odd harmonics.

A detailed paper is being published elsewhere.

## Damping of Turbulence by a Magnetic Field

IN experiments which I carried out in the summer of 1951, mercury flowing in a long narrow rectangular channel at a Reynolds number $R$ entered a region of constant transverse magnetic field $H$. The pressure gradient was measured downstream of any entrance effects.

For a given fluid, the pressure gradient can be shown to be a function of the dimensionless quantities $R$ and $M$, where $M = \mu Ha\sqrt{\sigma/\eta}$, and $\eta$ is the coefficient of viscosity. Hartmann[1] gives the theoretical form of this function for the case of laminar flow. Lundquist[2] gives theoretical reasons for expecting the critical value of $R$ to vary linearly with $M$.

My experiments covered the range $0 < M < 130$, $10^4 < R < 1{\cdot}2 \times 10^5$. With $M > 1{,}000\ R$, the pressure gradient agreed with Hartmann's laminar flow solution. With $M/R < 1{,}000$, the pressure gradient was larger than that predicted by the laminar flow solution. This suggests that turbulence is present, and confirms Lundquist's predictions.

The action of the magnetic field in damping turbulence has been studied. It appears that this damping is progressive with increasing field, as surmised by Lundquist. There was no evidence for the creation of turbulence near the walls due to the high rates of shear produced by the 'Hartmann effect', as suggested by Lehnert[3].

I wish to thank the Director of the Atomic Energy Research Establishment, Harwell, for permission to publish this letter.

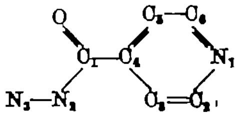
## Crystal Structure of *iso*Nicotinic Acid Hydrazide

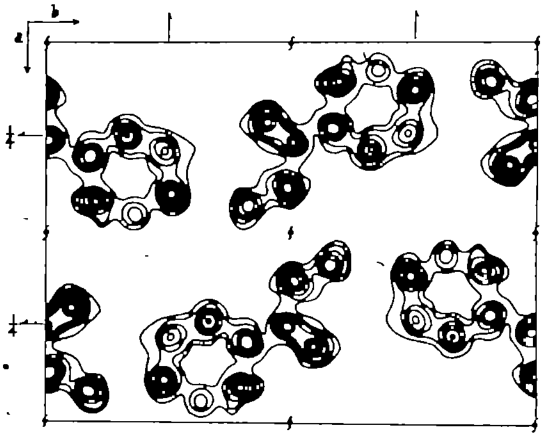
As part of a programme of X-ray diffraction studies of biologically important compounds, the crystal structure of *iso*nicotinic acid hydrazide ('Nydrazid') is being determined.

The lattice parameters and space group were determined from Weissenberg photographs about the $a$- and $c$-axes. The unit cell is orthorhombic, space group $P2_12_12_1$, with $a = 11{\cdot}33$ A.; $b = 14{\cdot}74$ A.; $c = 3{\cdot}84$ A. There are four molecules in the unit cell; calculated density $1{\cdot}42$ gm.cm.$^{-3}$; observed, $1{\cdot}41$ gm.cm.$^{-3}$.



Structural formula for *iso*nicotinic acid hydrazide

The intensities for $\{hk0\}$ were put on an 'absolute' basis[1], and an unsuccessful attempt was made to determine a set of signs for the larger $F$'s[2]. A Patterson projection on (001) showed the orientation of the ring, and the approximate position of the molecule was obvious from the magnitudes of $F_{110}$, $F_{120}$, $F_{200}$ and $F_{210}$. It was, however, immediately apparent from $F_{200}$ and $F_{210}$ that the 'absolute' intensities were high by a factor of $c.$ 3. Thus the expected root-mean-square unitary structure factor is 0·16; neglecting a relatively small temperature factor, observed value is 0·04. Furthermore, calculation of the ratio $(\overline{|F|})^2/\bar{I}$ for various intervals $0{\cdot}256 < \sin\theta < 0{\cdot}745$ showed a marked decrease in value for $0{\cdot}50 < \sin\theta$, the weighted average value being



Projection on (001) for *iso*nicotinic acid hydrazide. Contours are drawn at intervals of 1 $e$ A.$^{-2}$, contours below 2 $e$ A.$^{-2}$ omitted

0·50[3]. This is to be compared with a value of 0·637 to be expected for a projection which is centrosymmetrical[4].

Electron densities were calculated at units of $a/30$ and $b/60$, using Patterson–Tunell strips. Successive $F$ syntheses refined slowly. The seventh synthesis with seventy terms based on intensities estimated by eye is shown in the accompanying diagram.

The approximate $x$- and $y$-co-ordinates based on this synthesis are given in the table.

APPROXIMATE $x$- AND $y$-CO-ORDINATES

| | $x$ | $y$ |
|---|---|---|
| $C_1$ | 0·256 | 0·605 |
| $C_2$ | 0·224 | 0·742 |
| $C_3$ | 0·271 | 0·666 |
| $C_4$ | 0·212 | 0·583 |
| $C_5$ | 0·091 | 0·601 |
| $C_6$ | 0·045 | 0·680 |
| $N_1$ | 0·107 | 0·752 |
| $N_2$ | 0·377 | 0·490 |
| $N_3$ | 0·422 | 0·410 |
| O | 0·200 | 0·445 |

Integrated intensity data are being used in refinement of the (001) projection and the determination of the $z$-co-ordinates. A full account of this work will appear at a later date.

I wish to thank E. K. Squibb and Sons for the sample of crystalline 'Nydrazid' used in this study, and Dr. Wayne Chen, who performed most of the numerical work.

## A Dislocation Model for the Study of Boundary Phenomena and Deformation in Metals

IN an earlier communication[1], an account was given of an experimental examination of the behaviour of the crystal boundaries in aluminium and its alloys at temperatures near the melting point. In an extension of this work, some consideration was given to the results obtained by Achter and Smoluchowski[2] in their studies of the structure and properties of grain boundaries, and it was thought desirable to construct a dislocation model for a study of grain-boundary phenomena. It was hoped that this model would also prove of use in a related investigation of the mode of deformation of the crystals of a polycrystalline mass under a rapidly applied force.

The bubble model devised by Bragg[3], in which the atoms in a metal are represented by bubbles, is somewhat fragile and unsuited to withstand the rapid application of a force of any magnitude. In a search for a more robust method of construction of an atomic model, it was found that, if several hundred steel rods of suitable diameter ($\frac{1}{16}$–$\frac{1}{8}$ in.) and length are piled together longitudinally in a container, with the cut ends of the rods at one end of the container in the same vertical plane, the resulting pattern of the cut ends of the rods is similar to that of the bubbles in the bubble model. Fig. 1 shows that the rod model provides a useful schematic illustration of the atomic arrangement in a polycrystalline metal. The regions of atomic disorder at a crystal boundary are well defined. Single dislocations and lines of dislocation within the crystals are also apparent, one such line being shown on a larger scale in Fig. 2.

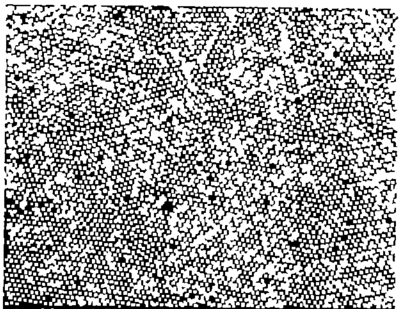

Fig. 1

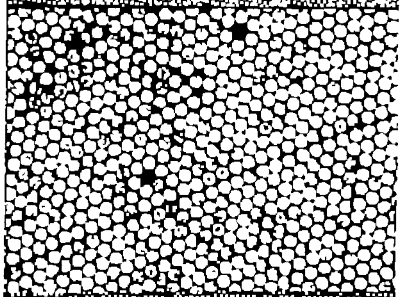

Fig. 2

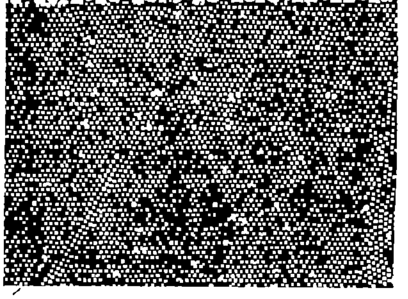

Fig. 3

Fig. 1. Atomic arrangement in a polycrystalline metal as represented by the rod model

Fig. 2. Single dislocations and line of dislocation in a crystal illustrated by the rod model (magnification greater than that of Fig. 1)

Fig. 3. Effect of introduction of atoms of larger size than average (white spots) into an atomic structure as represented by rod model

The rod model is robust and well suited for demonstration purposes. The effect of introducing atoms of large diameter into an atomic structure may be simulated by introducing rods of larger diameter than the average into the container (Fig. 3). If the container is made suitably flexible by hinging the sides or making them of more flexible material, the rod model may be used for observing the effect on a polycrystalline structure of the rapid application of loads of appreciable magnitude.

## Height of the Potential Barrier in Barrier Layer Cells

Measurements of the zero resistance of a number of barrier-layer cells[1] over a wide range of temperatures have shown that the theoretical expression:

$$R_0 = AT \exp(\varphi/T), \tag{1}$$

where $A$ and $\varphi$ are regarded as constants, is not obeyed over the whole range of temperatures. The power of $T$ appearing outside the exponential in equation (1) depends on the assumptions made in the theoretical treatment; values ranging from $+ 3/2$ to $- 1/4$ [2-4] have been obtained, but these do not significantly alter the shape of the curve. Accordingly, the value of unity has been used in this work. It is the purpose of this communication to put forward a possible explanation of the observed departure from equation (1).

In the case of selenium rectifiers, the existence of weak spots has been postulated to explain breakdown phenomena[5], and in germanium the multicontact theory[4] has been proposed to explain the forward characteristics of point-contact diodes. By a simple mathematical analysis of these postulates, it is possible to account for the zero resistance measurements. The barrier layer is considered as being made up of a number of elements in parallel, to each of which equation (1) applies. The parameter $\varphi$ is assumed to have a normal distribution among the elements about a mean value $\bar{\varphi}$ with standard deviation $S$. Then it is easy to show that, for the whole cell,

$$\frac{R_0}{T} = \frac{2A}{N(1 + \operatorname{erf} x)} \exp\left[\frac{\bar{\varphi}}{T} - \frac{S^2}{2T^2}\right], \tag{2}$$

where $N$ is the number of elements, and

$$x = \frac{1}{S\sqrt{2}}\left(\bar{\varphi} - \frac{S^2}{T}\right).$$

Equation (2) has been fitted to the results for a selenium rectifier, and the theoretical curve and experimental points are shown in the accompanying graph. A similar fit has been obtained with a commercial selenium photocell and germanium and silicon point diodes. Values of $\bar{\varphi}$ and $S$ obtained by fitting equation (2) to the experimental results are shown in the table.

| | $\bar{\varphi}$ (eV.) | $S$ (eV.) |
|---|---|---|
| Selenium rectifier | 0·69 | 0·09 |
| Selenium photocell | 0·86 | 0·12 |
| Germanium rectifier | 1·18 | 0·13 |
| Silicon rectifier | 0·47 | 0·07 |

It is clear from the experimental results that equation (1) cannot be used as a reliable method for the determination of $\varphi$, but $\bar{\varphi}$ and $S$ obtained from equation (2) will give some indication of the uniformity of the barrier layer.

The above calculations can be modified by allowing for an upper and lower limit for the distribution of $\varphi$; the shape of the curve is found to be sensitive to the lower, but very insensitive to the upper, limit. This is in agreement with the multicontact theory, where it is shown that it is the low-value tail of the distribution which is of primary importance. The upper limit may be less than $\bar{\varphi}$, so that the occurrence of $\bar{\varphi}$ greater than the width of the energy gap in the semiconductor need not imply that the individual barrier heights exceed this value ($\bar{\varphi}$ for germanium, 1·13 eV.; width of energy gap, 0·72 eV.). Detailed calculations of this sort were not considered worth while, as the data so far available do not justify the inclusion of yet another parameter.

## Molecular Weight Determination by Thermistors

A THERMISTOR is a resistance body which has a high negative temperature coefficient of resistance, and is a valuable circuit element with a large variety of applications. Thermistors can be used as sensitive thermometers in cryoscopic measurements[1] and also in place of thermocouples for measuring the lowering of vapour pressure of aqueous colloidal solutions[2]. At a condition of steady state, the droplets of solution and solvent deposited on the tips of the thermistors have a constant difference in temperature which can be measured as a difference of resistance in an A.C. bridge circuit. The construction and operation of a simple A.C. thermistor bridge, used for measuring the osmotic activities of aqueous solutions, has been described by McGee and Iyengar (submitted for publication elsewhere).

A pair of matched thermistors can also serve as a sensitive element for determination of molecular weights of compounds in organic solvents. The resistance differential $\Delta R$ set up per unit molal difference in concentration between the drops of solvent and solution ($k = \Delta R/m$) is generally much higher for organic solvents than for water; for example, $k = 12{\cdot}1$ ohms/mol. for water and $40{\cdot}1$ ohms/mol. for toluene in the case of a pair of Western Electric thermistors (Type 14$B$, resistance about 2,000 ohms at 25°). Thus, organic solvents increase the sensitivity of measuring the small difference of vapour pressure between the drops of solution and solvents.

Benzil was used as a standard substance for determining the calibration constant $k$ of the thermistors. The molecular weights of camphor, naphthalene, phenanthrene, and the two detergents 'BRIJ 30' and '35' were checked in two organic solvents, benzene and toluene, at 25° C. The results are summarized in the accompanying table.

| Substance | Molecular weight obs. | Molecular weight calc. | Substance | Molecular weight obs. | Molecular weight calc. |
|---|---|---|---|---|---|
| Naphthalene | 128·0 | 128·2 | | | |
| Camphor | 151·9 | 152·2 | 'BRIJ 30' | 435 | — |
| Phenanthrene | 177·6 | 178·2 | 'BRIJ 35' | 747 | — |

The range of concentration was 0·5–7 gm. of solute per 100 gm. of solvent. The mean average deviation of the readings is ± 0·25 per cent.

The results shown in the table were reproducible and independent of the concentrations and solvent used, within the limits of experimental error. The thermistor has been found to be extremely sensitive, and has the further advantages of being rapid in its operation and free from the spurious electrical effects that might be encountered within the D.C. thermocouple method of Hill-Baldes[3]. It is also seen to be far more accurate than the chemical boiling-point and vapour-pressure methods, thus permitting the study of very dilute solutions.

The Beckmann freezing-point method is limited to low temperatures, where the solubility of many substances is inadequate. However, the most important advantage of the thermistor technique over the usual Beckmann freezing-point method is the wide range of temperatures and solvents which can be employed in the measurements. Besides being far more accurate than the Beckmann methods, only a few drops of solution are required for the measurement.

With the present set of thermistors, the limit of molecular weight measurement is roughly 2,000 in water and 5,000 in benzene. As soon as more-sensitive thermistors become available, the method can be extended to compounds of higher molecular weight.

I wish to express my thanks to Prof. J. W. McBain, Dr. S. S. Marsden and Dr. B. R. Y. Iyengar for their suggestions and interest in the work.

## The Laws of Friction

The laws of static friction are usually described as: (1) $F = \mu R$, which governs the relation between limiting frictional force $F$ and normal reaction $R$; and (2) the coefficient of friction $\mu$ is independent of the apparent area of contact.

Exceptions to law (1) are now well established, and in the field of fibre friction have been known for some time. In these cases the friction is governed by an expression of the form $F = aR^n$, where $n$ has values for different materials ranging from 0·67 to 1·0, the value for metals. Thus Bowden and Young[1] obtain $n = 0·8$ for diamond, Lincoln[2] 0·67 for nylon and Howell and Mazur[3] 0·96 for cellulose acetate, 0·91 for viscose rayon, 0·90 and 0·80 for undrawn and drawn nylon respectively. This form of the frictional relation is more general than law (1), and it is the purpose of this note to point out certain consequences which arise from it.

(1) Amontons's law $F = \mu R$ represents the special case of $n = 1$.

(2) The frictional force $F$ now depends upon the apparent area, and only in the particular case of $n = 1$ is it independent. Consequently, the two laws as such are not independent, but law (2) is a natural consequence of law (1).

(3) If the effect of roughening a surface is to produce valleys large compared with the distance between surface asperities, then the area available for real contact is reduced with a consequent reduction in the frictional force.

(4) In the important case of friction of a string around a pin or cylinder, the tension relation $T = T_0 \exp \mu\theta$ is derived on the assumption $F = \mu R$. If the general expression $F = aR^n$ is used in the analysis, the relation becomes

$$\left(\frac{T}{T_0}\right)^{(1-n)} = 1 + (1-n) \,.\, a \left(\frac{\rho}{T_0}\right)^{(1-n)} \theta \,;$$

or, in the limit as $n$ approaches unity,

$$T = T_0 \exp a \left(\frac{\rho}{T_0}\right)^{(1-n)} \theta,$$

where $\rho$ is the radius of the cylinder, which is not involved in the usual treatment. The data on the tensions of wool fibres given by Martin and Mittelman[4] have been examined and found to conform to this expression.

(5) The coefficient $a$ in $F = aR^n$ is not dimensionless except when $n = 1$, but normally has dimensions $[\text{force}]^{1-n}$.

Again, in the case of the cylinder, since $F$ and $R$ in the analysis refer to unit length, the dimensions are $[\text{force/length}]^{1-n}$.

A full account of this work, which forms part of a programme of fundamental research of the British Rayon Research Association, will be given elsewhere.

## A Method of determining the Electrical Resistance of Fibre Bundles

Some years ago, one of us[1] showed that the quantity of static electricity developed on textiles during, for example, the carding operation, could be explained in terms of the electrical leak through the fibre; but the resistance measurements made at that time were limited to the order of $10^{11}$ ohms by the electric leak of the supporting frame.

We have recently devised a method which enables such resistance measurements to be made up to the order of $10^{17}$ ohms, and which avoids this leak by eliminating the supporting frame. In this method the bundle of fibres or sliver is hung vertically from a metal support to which is applied a voltage of the order of 5 kV., and the total charge resident on the fibre after a known period of application of voltage is measured by transferring the bundle to a Faraday cylinder.

SPECIMEN : COTTON

Applied voltage ($V$) = 5 kV. Final charge ($Q_\infty$) = 0·0285 μC.

| $t$ (hr.) | 0 | 0·4 | 0·6 | 0·75 | 0·9 | 1·0 | 1·2 | 1·5 | 1·8 | 2·85 | 3·1 | 3·5 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| $Q$ (μC.) | 0 | 0·014 | $0·016_5$ | 0·019 | 0·020 | 0·021 | 0·023 | $0·02_7$ | $0·025_5$ | $0·028_4$ | $0·028_5$ | $0·028_5$ |
| $Q/Q_\infty$ | 0 | 0·49 | 0·58 | $0·66_5$ | $0·70_5$ | $0·73_5$ | 0·81 | 0·88 | 0·89 | | | |
| $t/CRL^2$ | 0 | 0·19 | 0·27 | $0·36_5$ | 0·42 | 0·46 | 0·59 | $0·75_5$ | 0·82 | | | - |
| $CRL^2$(hr.) | | 2·1 | 2·2 | 2·1 | 2·1 | 2·2 | 2·2 | 2·0 | 2·2 | | | |

Average $CRL^2$(hr.) = 2·1 $CL = \frac{Q_\infty}{V} = 5·7$ μμF.

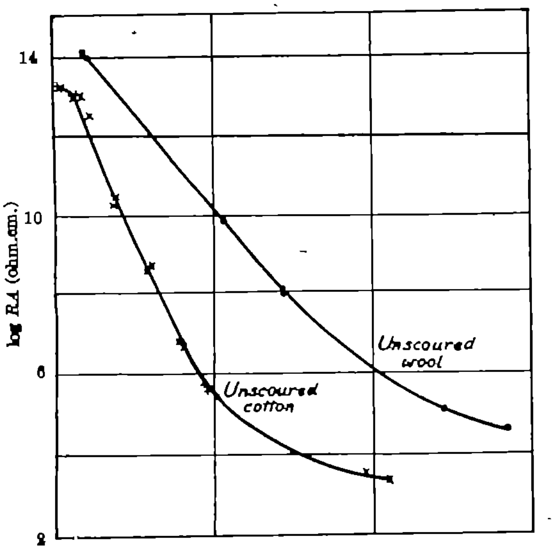
$$RL = \frac{2·1 \times 36 \times 10^{14}}{5·7} = 1·3 \times 10^{15} \text{ ohms.}$$

The equation for the voltage at any point in the bundle is identical with that describing the flow of heat in a conducting rod, and a convenient solution is given by Carslaw and Jaeger[2]. Integrating their expression, a graph is obtained between the ratio of total charge to the equilibrium charge and the product $t/CRL^2$ (where $t$ is time in sec., $R$ is resistance per unit length in ohms, $C$ is capacitance per unit length in farads and $L$ is length of the sample). $CL$ is, of course, equal to the final charge on the sample divided by the applied voltage. A set of experimental results using this method is shown in the table.

In our experiments the samples are suspended axially in a metal pot 45 cm. in diameter, and this vessel has passed through it a current of air at controlled relative humidity. Some typical curves connecting moisture regain and electrical resistance are shown in the accompanying graph.

At resistances of the order of $10^{12}$ ohms, the times involved become too small for convenient measurement; but at this level the normal condenser-discharge method, using a capacitance of the order of 200 pF., can be used if the lower end of the fibre bundle is also bound with a fine wire. The new method gives results consistent with those by the conventional condenser-discharge method at this level.

The rate of charge method can be applied to single textile fibres. The method we have found most convenient is to secure a $\frac{1}{16}$-in. bearing ball to the lower end of the fibre, which is then charged by applying voltage to the other end. The relevant mathematical formula is again provided by Carslaw and Jaeger[3].



Resistance regain for card slivers

Preliminary experiments show that the resistance of single fibres is of the same order as, but lower than, that calculated from the experiments made with fibre bundles or slivers. It is hoped that these differences will enable the effect of lateral contact resistance in a sliver of staple fibre to be evaluated.

It is hoped to publish a detailed account of these experiments in the near future.

## Molecular Configuration of Dextrans in Aqueous Solution

Ingelman and Halling[1] have made measurements of sedimentation, diffusion and viscosity of fractions of dextran subjected to partial hydrolysis. On the basis of sedimentation and diffusion alone, and neglecting solvation, they concluded that the dextran particles are considerably elongated (length/thickness varying between 17 and 110).

Fessler and Ogston[2] and Ogston and Stanier[3] have shown that both the asymmetry and the solvation (effective volume) can be deduced from measurement of the sedimentation constant and any pair of: diffusion, intrinsic viscosity and the variation of sedimentation constant with concentration. It is of interest to examine Ingelman and Halling's data from this point of view.

The procedure chosen is as follows: from the sedimentation constant at zero concentration and the intrinsic viscosity (using Perrin's[4] and Mehl, Oncley and Simha's[5] relationships) sets of values of the axial ratio $p$, the effective volume $V'$ ml. per gm. of unsolvated solid, and the unsolvated molecular weight $M$ are obtained. From these quantities, values of $d(1/s)/dc$ are predicted. The values of $M$ obtained from $S_0$, $D_0$ and $\overline{V}$ (partial specific volume), and the observed values of $d(1/s)/dc$ are then compared with the predicted values.

The values of $M$ in every case are close to those predicted for an axial ratio of 1 and, where the data are sufficient to give reliable estimates of $d(1/s)/dc$, these indicate values of the axial ratio of less than 10.

The corresponding values of $V'$ vary between 3 ml./gm. for $M = 14{,}000$ and 30 for $M = 3 \cdot 3 \times 10^6$, indicating considerable degrees of solvation. Kuhn and Kuhn[6] have shown that the effect of branching of a flexible chain is to reduce the volume which it occupies in solution compared with that occupied by an unbranched chain of the same total length (that is, the same molecular weight). The volumes deduced above lie between 0·17 and 0·09 of the volumes predicted by the theory of Kuhn and Kuhn for unbranched flexible chains of glucose units, and this agrees with the chemical evidence[7] in suggesting a high degree of branching.

We conclude that the data available indicate that dextran particles in solution are highly solvated and not very asymmetric, and that this view is consistent with what is known of their chemical structure.

## Thermochromism and Keto-Enol Tautomerism of Solutions of 1 : 3-Diketo-2-phenyl-5-bromoindan

In connexion with the growing interest in the phenomenon of thermochromism[1], we should like to describe some experiments with 1 : 3-diketo-2-phenyl-5-bromoindan (I). In contrast to 1 : 3-diketo-2-phenylindan, which exists only in a colourless, solid form, (I) exists in a deep violet, solid form (IIa or IIb) and an almost colourless, solid, ketonic form (I). Koelsch[2], who discovered these forms, stated that by crystallization from non-polar solvents the white modification is obtained, and from polar solvents the violet-black modification is formed; he mentioned only acetic acid and benzene as solvents. According to our observations, dilute solutions of the violet-black form in ethyl benzoate are orange at − 10°, whereas at the boiling point of the solutions they are light-yellowish. The process is reversible and may be explained by assuming that, at high temperatures, the keto form is predominant, whereas in the cold the enol form (IIa or IIb) is present in greater concentration. This opens a route for the investigation of the position of the equilibrium between the keto and the enol forms in relation to temperature by the investigation of the visible spectrum.

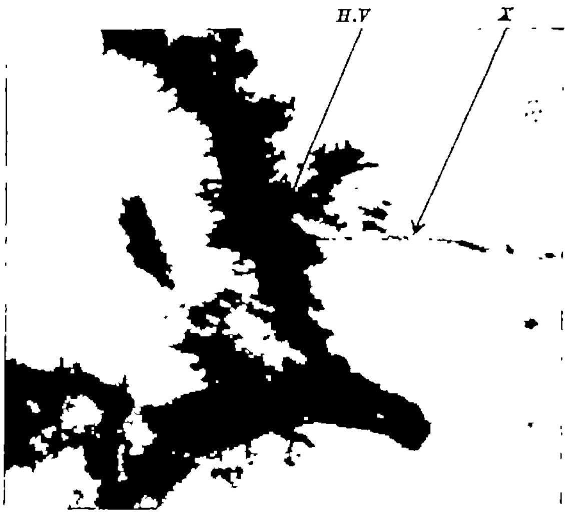
## Anatomical and Physiological Evidence of Anastomosis of the Hepatic Artery and Hepatic Vein within the Mammalian Liver

That the hepatic artery sends direct branches to the hepatic vein in the livers of Amphibia has been established[1]. Several workers have reported translobular branches in mammalian livers; but the evidence is frequently indirect. Chronszczewsky[2], Braus[3] and Loeffler claim to have seen such a vessel; Elias[4] is a protagonist of the view of Chronszczewsky, whose work he has repeated; he also reports that the arterial blood gains the centre of the lobule via thin-walled capillaries which run in close apposition to the parenchyma. Seneviratne[5], using a trans-illumination technique, also supports the existence of translobular arterial vessels. Owing to technical difficulties these arterial vessels have not been shown convincingly, and their presence is not yet generally accepted.

The vessels can, however, be demonstrated by the following technique. Immediately after death the liver is washed with a slightly alkaline solution[6]. When the organ is free from blood, the portal venous system is blocked by perfusion of the portal vein with a suspension of kieselguhr in saline. 'Hycar' latex is then put into the arterial system at a pressure of about 200 mm. mercury and, afterwards, coloured neoprene is run into the hepatic vein in a retrograde direction at a pressure of 30 mm. mercury. The organ is then fixed in acid formalin, and a cast of the vascular system obtained by digestion with commercial hydrochloric acid.

The completeness of the injection varies somewhat from liver to liver. In successful preparations the arterial and hepatic venous trees are well injected, and only isolated segments of the portal venous tree appear; the sinusoids are frequently not filled, except for localized areas. On occasion, the hepatic tree has been almost fully filled from the arterial side without injection of sinusoids. This filling is achieved by means of direct arterio-venous anastomoses, one of which is shown in the accompanying photograph.



Arterio-venous anastomosis *H.V.*, hepatic vein. *X*, anastomosing branch of the artery

In these specimens it is impossible to retain the normal relationships of the vessels, and one cannot determine the angle at which the vessels run before joining. There is no constant pattern, but the majority of the arterial vessels run into the base of small sublobular veins; they appear to be more frequent in the deeper parts of the parenchyma. Owing to distortion of the vessels by the injection technique, their size cannot be estimated with certainty, but they appear to be arterioles. Occasionally they split into a few short sinusoids before joining the hepatic venous tree. From the unbranching path taken by most of these vessels they appear to be shunts, and not concerned with the maintenance of parenchyma. They have so far been demonstrated in rats, rabbits and guinea pigs.

Supporting physiological evidence has been elicited from perfusion of isolated canine livers. Acetylcholine produces an increase in hepatic volume and a diminution of outflow when injected into the hepatic artery in amounts of 0·25–1·0 μgm.: ten to twenty times the amount is required to give a similar response if introduced into the portal vein[7]. Also, on occasion, adrenaline may give rise to swelling of the liver when put into the hepatic artery, and invariably produces a diminution of volume when put into the portal vein. The variation of the action of these drugs according to the vessel of administration is strong evidence in favour of different intrahepatic pathways of arterial and portal venous blood, especially as in each case increase of liver volume is due to reduction of outflow and not to increase of inflow, suggesting that the site of action is on the hepatic veins.

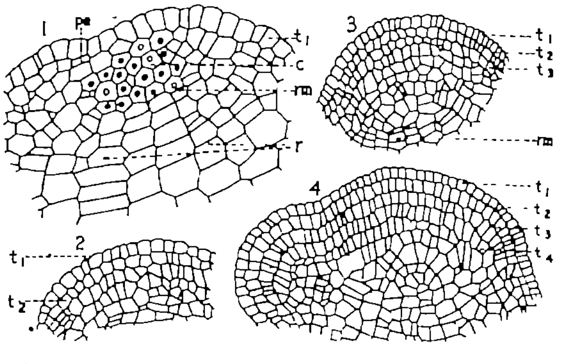
## Organization of Shoot Apex during the Ontogeny of *Brassica campestris* L.

OUR knowledge of the organization of shoot apices is confined mostly to mature plants, and there has been very little work on the ontogenetic changes occurring in them[1]. Certain interesting observations on the above topic came to light during a comparative anatomical study of vernalized and control plants[2] of mustard. Microtome sections of: (1) seeds soaked for six hours in water; (2) seedlings collected at intervals of twenty-four hours up to seven days and then on the ninth day; and (3) vegetative and reproductive apices formed fifteen and twenty-nine days after sowing were cut 13 μ thick and stained with hæmatoxylin and safranin.

The apical meristem of the resting embryo is a dome-shaped structure with a uniseriate tunica (Fig. 1) surmounting the corpus, the central cells (*c*) of which are polygonal, more or less isodiametric and deeper stained. The cells of the rib-meristem (*rm*) and the rib (*r*) converge above to this group of central cells and appear to be originating from them. These central cells could not be distinguished in seedlings more than twenty-four hours old. This type of zonation in the apical meristem is quite different from any so far observed[1,3-5]. The periclines (*pe*) present in the second layer of the apical meristem of the embryo become rarer with an advance in age, and in seedlings nine days old the tunica is biseriate (Fig. 2). The cells of the next layer now begin to show a stratified form. Occasional periclinal divisions, however, continue to occur here and shoot apices of fifteen-days-old plants show two or three layers of tunica (Fig. 3). In a reproductive shoot the tunica layers, composed of more-or-less columnar cells, increase further to three or four (Fig. 4) and the corpus appears to be replaced by vacuolating cells. One or more layers of cells below the central part of the tunica are also stratified.

There is scarcely any activity of the rib meristem for the first five days, and the growth of the epicotyl is due to a progressive elongation of rib cells. At an age of six days, however, the rib meristem becomes suddenly active and gives rise to several layers of transversely elongated cells. In seven- and nine-day-old seedlings no fresh similar cells are formed and the pre-existing ones enlarge longitudinally. Normally, it is expected that the rib meristem, once active after germination, would continue to be so, and thus its behaviour in the present case is rather interesting. In the shoot apices of fifteen-day-old plants, the



Figs. 1–4. Median longitudinal section through the shoot apices of mustard: *c*, central group of cells; *pe*, periclines; *r*, rib; *rm*, rib meristem; $t_1$–$t_4$, different layers of tunica. Fig. 1, from seeds soaked for 6 hr. Fig. 2, from seedlings 9 days old; Figs. 3 and 4, from plants 15 and 29 days old, respectively. All × 200

rib meristem assumes a semi-circular form extending from almost one flank of the apex to the other (Fig. 3, *rm*).

Procambial strands differentiate acropetally in the apex before the leaves, which they are going to supply, arise. Similar cases have been recorded by several workers[1,4,6,10].

Variation in the number of tunica layers within the same species has been accounted for in *Garrya* by the stages of development of leaf primordia by Reeve[8,9]. I, however, failed to observe this in my materials, and so did Millington and Gunckel[6]. In mustard, the variation in the number of tunica layers appears to be related to the growth conditions of the shoot. During the vegetative phase there is scarcely any appreciable elongation of it. At the onset of the reproductive phase, the main axis grows in length very rapidly and its apex shows the maximum number of stratified layers (5–6). Majumdar[5] observes that, in shoot apices of *Heracleum*, there are 5–6 stratified layers on the flanks in contrast to only three at the apex. Here, too, the increased number on the flanks is related to the growth conditions of the plant, which possesses a "rapidly widening axis just below the apical cone without any vertical expansion". Similar positive correlation is observed in (1) *Liriodendron*[6], where there are more tunica layers in the active stage, and (2) *Tropaeolum*[11], the young axillary shoot apices of which have only a uniseriate tunica in contrast to 2–3 in the main shoot.

I am grateful to Prof. B. Singh and Prof. G. P. Majumdar for their kind criticisms and suggestions.

## Regeneration of the Potato Shoot Apex

MR. I. M. SUSSEX[1] propounds a problem of great importance and interest, but the main conclusion which he draws from his skilful experiments appears open to question. He has found that in shoots of potato lateral portions of the apical meristem which are separated by longitudinal cuts from the main part are often prevented from regenerating by the growing-point of that meristem, or if they do regenerate are soon inhibited by it in their growth. He concludes that since the inhibiting influence has travelled down to a level below the cut and up again to the separated piece of meristem, it must be based not on a transport of hormones but on a competition for nutriment. He supports this conclusion by mentioning some unpublished experiments which, he states, have shown that there is in these apices a transmission of some other kind of hormone-like stimulus which, after travelling in the morphologically downward direction, cannot travel up again.

These other results will be awaited eagerly; but it remains quite possible that the transmission of inhibition from the growing-points of these apices is based on a transport of hormones, since one kind of stimulus or influence may follow different rules of transmission from another, even if both are based on hormones. Thus in shoot systems the stimulus for cambial growth, which comes from developing buds and leaves, travels strictly in the morphologically downward direction only[2]. But correlative inhibition, coming from the same source, can travel down one shoot and up another orthotropic shoot, even when the transpiration stream in the latter has been artificially reversed[3]. Also, in many plants an influence coming from the main apical bud keeps the branches plagiotropic, and this must travel down the main stem and out along the branches to their tips. Yet all these transmissions are based on transport of hormone; and, indeed, the first stage is the same in all of them, being the formation of auxin by developing leaves near the apex and its transport down the stem[4–8]. If an explanation of the difference in further transmission be sought, it may be suggested that the cambium is stimulated to grow by the descending auxin itself, whereas the other two effects depend on other substances which can be transported upwards as well as downwards and are formed either from the descending auxin, by modification of its molecule, or as a result of its action[9]. Similarly, there may be different transmissions within the apical bud also.

It may also be remarked that although Mr. Sussex emphasizes the fact that the lateral pieces of meristem which he isolated by vertical cuts were either prevented by the growing-point from regenerating at all, or else were afterwards inhibited by it, it seems of equal interest that some of them did regenerate to form buds with two or three leaves, so that these pieces must have been partially released from inhibition. In this respect his results are rather similar to those of experiments on *Lupinus albus* in which, for another purpose, we isolated the youngest leaf or the presumptive area of the next leaf due to arise, or of the next but one, by similar vertical cuts[10]. For in many of these experiments, in which enough apical tissue was left on the isolated piece axillary to the isolated leaf, a bud was formed from this tissue, although neighbouring leaves of the same seedlings had no axillary buds. These buds grew quite strongly, so that they must have been released from inhibition nearly completely.

---

WHILE I agree that there is much justice in the comments on my communication[1], the main fact which needs emphasis at this stage is that we are still very much in the dark concerning the roles of hormones and general nutrients in growth and morphogenesis at the shoot apex.

Fig. 1 of my communication showed in plan a potato shoot apex in which a small lateral panel *a* had been isolated from the remainder of the apical meristem *A* by a single vertical incision which penetrated all the meristematic cell layers and just into the differentiating sub-apical region. On further growth of such shoots the panel *a* usually failed to regenerate, remaining totally inhibited, although its cells retained their embryonic appearance. The incision was considered to prevent direct hormonal inhibition of the panel *a* by the larger part of the apical meristem; but the two separated parts of the apical meristem would still be able to compete with one another for a share of the available nutrients in the sub-apical region. The further growth of each would be a measure of its ability to grow under such conditions of competition. The results have been described (*loc. cit.*).

In support of this hypothesis, further experiments in which the incision was 4–5 mm. deep were carried out. Such incisions penetrated deeply into the maturing zone of the shoot, where nutrients may be expected to be localized in the vascular tissue. In such shoots the sub-apical nutritional competition between the separated parts of the apical meristem is eliminated, but it is still possible for substances to pass downwards in the stem from *A*, below the incision, and upwards into the panel *a*, that is, hormonal correlative inhibition of the panel *a* would still be possible.

Three types of deep incisions were made: (1) vertical, (2) undercutting the panel *a*, (3) undercutting the remainder of the apical meristem *A*. By such sloping incisions it was possible to provide either of the separated parts of the meristem with increased amounts of nutrients derived from a greater relative area of the mature shoot.

In each treatment eight shoots were used, and the cut surfaces were prevented from regrafting by placing a fragment of mica in each incision. The average number of leaves on the lateral panel *a* and the main apex *A* in each treatment after six days is presented in summary form in the accompanying table.

| (1) Incision vertical | | (2) Incision undercutting *a* | | (3) Incision undercutting *A* | |
|---|---|---|---|---|---|
| *a* | *A* | *a* | *A* | *a* | *A* |
| 2·9 | 4·3 | 0·4 | 3·9 | 2·9 | 1·5 |

In treatment 1, all eight of the lateral panels *a* regenerated completely, and the results obtained with a deep incision thus differ sharply from those following a shallow incision when regeneration is infrequent. In treatment 2, the strongly growing main apex *A* of several shoots was excised after six days, leaving only the inhibited panel *a*, which then usually began to grow and formed two to three leaves in the following six days. In treatment 3 it is noteworthy that the growth of the larger meristematic region *A* has been 'inhibited' by the smaller panel *a*.

In these treatments the more rapidly growing meristem became considerably enlarged, even if it was initially very small, and gave rise to leaves which were much larger than those on the slow-growing shoot. As a result of these experiments it is felt that the inhibition of growth in lateral parts of the apical meristem is achieved in large part by a depletion of nutrients in the immediate vicinity of the inhibited meristems. Growth hormones may well be of importance in such inhibition but would appear to have an indirect effect, perhaps acting in the mobilization of nutrients towards the more actively growing regions of the meristem.

## *Amœba discoides* recorded for Milngavie, Dunbartonshire

The inoculation material for our stock cultures of *Amœba* at Notre Dame was procured either from Killarney or Milngavie. From the outset each culture was numbered and its subsequent history entered in a field-book, so that we know the origin and history of any material given to the various universities and schools which have asked for it during the past thirty years. Early on, it was suspected that culture 14 was different from the other cultures, but many researches were pressing, and I had not time to look into the matter. The culture accumulated and sub-cultures were made. In 1949 and 1950 I devoted time to the examination of the cytoplasmic movements of the individual amœbæ and concluded that they were not those characteristic of *A. proteus*. In 1952 I completed the investigation. The creatures in culture 14 are *Amœba discoides*, the life-history of which has been worked out by Sister Carmela Hayes[1]. Up to date, the species has been recorded from the neighbourhood of Oxford and Grimsby.

## Flight-tone and Wing-stroke Frequency of Insects

In his interesting article, Dr. O. Sotavalta[1] discusses the estimation of the wing-stroke frequency of insects by their audible note. This method is older than he suggests. ". . . and I took coach, having first discoursed with Mr. Hooke a little, whom we met in the streete, about the nature of sounds, and he did make me understand the nature of musicall sounds made by strings, mighty prettily; and told me that having come to a certain number of vibrations proper to make any tone, he is able to tell how many strokes a fly makes with her wings (those flies that hum in their flying) by the note that it answers to in musique during their flying. That, I suppose, is a little too refined; but his discourse in general of sound was mighty fine." (Samuel Pepys, August 8, 1666.)

Doubtless Pepys would have been pleased to know that his criticism had been met.

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. K. A Kermack: "The Origin of Mammals".*

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m. and 7.30 p.m.—Symposium on "Acetylene Chemistry".

Society of Chemical Industry, Corrosion Group (joint meeting with the Nottingham Section of the S.C.I., at the Gas Showrooms, Parliament Street, Nottingham), at 7.15 p.m.—Dr. J. C. Hudson and Mr. J. F. Stanners. "Atmospheric Corrosion and Atmospheric Pollution".

## Friday, February 6

Physical Society (in the Department of Meteorology, Imperial College of Science and Technology, Exhibition Road, London, S.W.7), at 2.15 p.m.—Discussion on "Physics of the Upper Atmosphere".*

Royal Institute of Philosophy (at University Hall, 14 Gordon Square, London, W.C.1), at 5.30 p.m.—Prof. J. N. Findlay: "Wittgenstein's Philosophical Studies". (Further Lecture on February 12.)

Society of Dyers and Colourists, London Section (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Mr. F Ward: "Methods and Principles of Textile Fireproofing".

Society of Chemical Industry, Plastics and Polymer Group (joint meeting with the Manchester Section, in the Chemistry Lecture Theatre, The University, Manchester), at 6.30 p.m.—Mr. J. R. Whinfield: "Textile Fibres—Variations on some Familiar Themes" (Jubilee Memorial Lecture).

Society of Cosmetic Chemists of Great Britain (in the Conference Room, British Colour Council, 13 Portman Square, London, W.1), at 7 p.m.—Dr. J. G. Fife: "Patents".*

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Henry Seligman. "Production and Uses of Radio-isotopes".

## Saturday, February 7

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. Hurustiati Subandrio: "The Toradja—Peoples of Central Celebes".*

---

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Director (with a good degree, preferably with first-class honours, in natural science, including chemistry or physics) of Examinations in Science—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 4183/53 (February 7).

Physicist or Electronic Engineer to assist in research and clinical work on the applications of physics to diagnostic radiology, and a Physicist to assist in work on the medical applications of radioactive isotopes—The Secretary, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, London, S.W.3 (February 7).

Physiologist (with a good honours degree in physiology, or equivalent qualification, and research experience preferably involving the perfusion of isolated organs) for research on the bovine udder—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 53/8 (February 7).

Biochemist (principal or senior grade)—The Secretary, South Worcestershire Hospital Management Committee, Royal Infirmary, Worcester (February 9).

Lecturer in Physiology—The Registrar, King's College, Strand, London, W.C.2 (February 14).

Principal of the East Riding Institute of Agriculture, Bishop Burton—The Chief Education Officer, County Hall, Beverley, Yorks (February 14).

Superintending Scientist at the Long Range Weapons Establishment, Salisbury, Australia, for the direction of research and development work concerned mainly with methods of investigating the behaviour and performance of guided missiles and with flight research on guided missiles—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1 (February 14).

Senior Research Fellow in the Departments of Economics and Pacific History, Australian National University, Canberra—The Secretary, London Office of the Australian National University, 27 Russell Square, London, W.C.1 (February 15).

Assistant Instructor in Physics and Applied Mathematics at the Ethiopian Air Force Training School—The Educational Adviser, Imperial Ethiopian Embassy, 17 Princes Gate, London, S.W.7 (February 16).

Assistant Lecturer or Lecturer in the Department of Civil Engineering—The Registrar, The University, Liverpool (February 23).

Senior Lecturer or Lecturer in Mathematical Statistics, and Lecturers in Psychology, Veterinary Anatomy, Veterinary Physiology and Veterinary Farm Clinic, at the University of Sydney—The Secretary, Association of Universities of the Commonwealth, 5 Gordon Square, London, W.C.1 (March 7).

Educational Psychologist for Child Guidance Department—The Medical Officer of Health, Civic Centre, Southampton.

Engineers and Physicists (particularly with electronics) in (a) Senior Scientific Officer and Scientific Officer grades (Ref. A.246/52A) and (b) Senior Experimental Officer, Experimental Officer and Assistant Experimental Officer grades (Ref. A.247/52A) in Admiralty Experimental Establishments in London, Portsmouth, Weymouth areas, and Scotland—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

Experimental Officers in the Guided Weapons Department, Royal Aircraft Establishment, Farnborough, for work on design, development and performance of new weapons and associated guidance and control systems; instrumentation of flight trials and investigations of trials results—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.508/52A.

Graduate (with honours degree in chemistry or metallurgy) to undertake research in the methods of preventing corrosion of iron and steel—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, endorsed 'Corrosion'.

Graduate (with good honours degree in chemistry or metallurgy) to carry out research into chemical reactions of interest in iron and steel making—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, endorsed 'Slags'.

Head Statistician—The Director, British Boot, Shoe and Allied Trades Research Association, Satra House, Kettering.

Lecturer or Assistant Lecturer in Inorganic Chemistry—The Registrar, The University, Nottingham.

Mining Geologist (with a first- or second-class honours degree in geology, or higher qualification) in the Local Civil Service of the Gold Coast, to undertake geological mapping in the field and underground—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE 105/13/53.

Physical Metallurgist (university degree or equivalent essential) to carry out research on the ageing of mild steel (location: Sheffield)—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, endorsed 'Ageing of Steel'.

Physicist interested in mechanics (with an honours degree or equivalent) for study and instrumentation of felting machines—The Director, British Hat and Allied Feltmakers Research Association, Stanley House, Manchester Road, Fairfield, Droylsden, Manchester.

Scientific Officer (Grade II) in the Operational Research Division at Euston Square, to undertake research on a wide variety of railway subjects—The Director of Research, Railway Executive, 222 Marylebone Road, London, N.W.1.

Scientific Officer or Senior Scientific Officer (with an honours degree or its equivalent) for the determination of solidification sequences in cast iron by temperature gradient measurements, as part of an investigation on the soundness of iron castings—The British Cast Iron Research Association, Alvechurch, Birmingham.

Senior Scientific Officers (with at least a second-class honours degree in chemistry or metallurgy, or equivalent, and three years postgraduate research experience) at Sellafield: (Ref. 404) for research in physical and inorganic chemistry (experience in fluorine chemistry, ion exchange, and radiochemical techniques desirable), and (Ref. 405) for research in metallurgy of radioactive materials—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting the appropriate Ref. No.

Tutorial Assistant (with a good honours degree in mathematics, including statistics) in the Department of Economics, to assist in the first year in statistical research, with a view to appointment as Assistant Lecturer in the field of Statistics and Mathematical Economics—The Registrar, The University, Nottingham.

# THE PROPOSED SCIENCE CENTRE FOR LONDON

IT is now approaching ten years since Sir Henry Dale in his presidential address to the Royal Society raised the question of the need for a national centre of science capable of progressive adjustment to changing needs. Referring to the missed opportunities of the past, largely through Government procrastination, and the congested and unsuitable conditions in which not only the Royal Society but also the Chemical Society and other scientific societies were then housed, Sir Henry claimed that the progressive needs of our scientific societies should be given early consideration in any new allotment which plans for reconstruction might allow. He thus recognized that expansion would of necessity be linked with the reconstruction which the destruction and changes due to the War had necessitated in London as a whole; but he also added that we ought nevertheless to have a scientific centre permitting scientific societies in Britain to co-ordinate their activities with economy and giving room for change, expansion and organic growth. "We have the further right," he concluded, "to expect that the home of science, in this capital city, will have a dignity symbolizing its value to the nation and the empire, and enabling us to hold up our heads in the company of other countries, whose scientific academies, not more famous than ours, have so long been housed more worthily, and with a more generous recognition of their due place in an enlightened people's scale of cultural values."

That claim for adequate and dignified accommodation for science in the Metropolis has been frankly acknowledged, but it is clear that the nature of the claim is still but imperfectly appreciated, not only by the Government but also by the ordinary citizen. Somewhat more tangible support has indeed been accorded than was received by the earlier schemes which were put forward in 1930 by the late Sir Arnold Wilson, and by Prof. J. F. Thorpe in his presidential address to the Chemical Society. The scheme then proposed contemplated what was described at the time as a certain amount of rationalization of the scientific societies concerned. These included, besides the Chemical Society, the Institution of Mining and Metallurgy, the Institution of Mining Engineers, the Society of Chemical Industry, the Institution of Chemical Engineers, the Institution of the Rubber Industry, the Institution of Petroleum Technologists, the Institute of Fuel, the Institute of Metals, the Iron and Steel Institute, the Faraday Society and the Physical Society. All these societies were to be housed under one roof, and their libraries were to be pooled for the common use of their members.

The need for such a scheme had been even then realized, so far as chemistry was concerned, for at least ten if not twenty years, and the central library was one of the chief features of the scheme for the chemical societies, which would have shared two-fifths of the space. Nevertheless, an approach to the

Treasury at the time resulted in a refusal of financial assistance, although the Government expressed sympathy with the scheme. An Association was formed to collect funds and erect and administer a building; but the raising of the necessary £140,000 proved too much for the chemical societies concerned, in the difficult circumstances of the financial depression then prevailing, and the only tangible result has been a larger measure of co-operation between some of the chemical societies themselves.

As a result of Sir Henry Dale's address, however, on October 13, 1944, Mr. C. R. Attlee (Lord President of the Council), Sir John Anderson (Chancellor of the Exchequer) and Lord Portal (Minister of Works) received a very representative deputation from learned societies regarding the needs and claims for accommodation of the societies which aim at promoting the independent advance of the fundamental sciences. The deputation was assured of the interest of the Government, and Sir Henry Dale was asked to submit a quantitative statement of needs. In 1947 the Scientific Societies Accommodation Committee was set up to review the alternative schemes and facilitate a close estimate of the needs of the societies. The idea of extending facilities in Burlington House or its vicinity was abandoned in favour of the conception of a Science Centre; and when on July 7, 1948, a second deputation was received by the Lord President of the Council, the Chancellor of the Exchequer and the Minister of Works, the agreed list of participants included the Biochemical Society, the British Association, the Chemical Society, the Faraday Society, the Geological Society, the Linnean Society, the London Mathematical Society, the Physical Society, the Physiological Society, the Royal Anthropological Institute, the Royal Astronomical Society, the Royal Meteorological Society, the Royal Society, the Royal Statistical Society and the Society of Chemical Industry. It was also understood that many of the smaller scientific clubs and societies would receive hospitality under the new arrangements.

The deputation was much encouraged by its sympathetic reception and was given to understand that the Government was prepared to acquire a site and contribute to the cost of building, but that the building must be the societies' own responsibility. The deputation pointed out that this would involve indefinite postponement, except perhaps for societies having close association with industry, and expressed the hope that the Government would reconsider this attitude and provide the site, the buildings and rent-free accommodation in them. Nevertheless, detailed arrangements were made to carry the project to a further stage, although a particular scheme discussed in negotiations with the Ministry of Works in April 1949 was eventually abandoned.

In the early autumn of 1950 the Royal Society was informed that the scheme for a Science Centre had made great progress. An adequate, central site had been selected and the Treasury had offered to provide the cost of building. On November 21, 1950, Mr. Herbert Morrison, then Lord President of the Council, in reply to questions in the House of Commons by Mr. M. Phillips Price and Sir Wavell Wakefield, stated that since the matter had last been raised on May 5, 1950, the remaining obstacles to the adoption of the Royal Society's long-term proposals had been overcome. Mr. Morrison emphasized that it would be some years before such a centre could be built, but that a start would be made on it as soon as resources could be found, having regard to other urgent claims. Provision would be made for accommodating also within the area the Patent Office and its Library, which would be modernized and extended as a first-rate central reference library on science and technology.

The Lord President added that suitable new quarters would be built for the Royal Society and for other leading scientific societies with their important special libraries, and new offices for the Department of Scientific and Industrial Research and for other Government scientific organizations would also be provided, thus releasing buildings elsewhere and achieving some economies in building requirements. The Centre would be designed to improve facilities and contacts between scientists and users of science, both nationally and internationally. Much detailed planning was still required, but Mr. Morrison said that he hoped to announce the selection of a site early in 1951, although it would be some time before a final scheme could be developed.

The decision that the proposed Science Centre should include provision for a first-class central reference library on science and technology was obviously prompted by the specific recommendation of the Royal Society Scientific Information Conference of June–July 1948, which urged increased support by the United Kingdom Government of central scientific libraries and information services, particularly of the Science Museum Library and the Patent Office Library. In spite of the association of these Government libraries and of the Department of Scientific and Industrial Research with the proposed centre, Sir Robert Robinson, in commending the scheme to the Royal Society in his presidential address on November 30, 1950, was emphatic that there was no evidence of any attempt or desire to undermine the independence of the Royal Society or to make it subservient to any material or political interest. The Lord President of the Council had indicated his full concurrence in the importance of maintaining the prestige and independence of the Royal Society, and in certain conditions for securing this in a Science Centre which had been put before him. The great national value of the Society as a focus of the scientific activity of the Commonwealth was recognized.

No further statement was made by the Government until, in response to a motion by Lord Samuel in the House of Lords on June 11, 1952, asking how the matter stood, the Lord President of the Council, Lord Woolton, gave the assurance that the present Government was in agreement with the statement made by its predecessor on November 21, 1950. No final decision had been made; but Lord Woolton confirmed that a site on the South Bank immediately below Waterloo Bridge and facing Somerset House had been reserved for a Science Centre by the London County Council, which is the planning authority, and was so reserved in the County of London Plan. Lord Woolton could give no assurance as to when the Science Centre would come into existence; but he pledged himself to use his own influence to ensure that it would eventually be constructed on that site.

Strong support for these proposals has been forthcoming from the Advisory Council on Scientific Policy. In its third report, in July 1950, the Advisory Council noted the finding of the Panel on Technical Information Services of the Committee on Industrial Productivity that the development of technical library facilities in Britain had failed to keep pace with the growth of scientific research, and that in consequence scientific and technical libraries were no longer capable of maintaining full collections of technical literature, and of providing reasonable facilities for readers. The Panel, in its report on Technical Information Services, urged the development of a central reference library in London, if possible in close association with specialized libraries of the learned societies, as well as of a national lending library of science and technology, not necessarily in London.

The Panel itself suggested that the Patent Office Library might form the basis of the proposed central reference library; and, agreeing with the broad objectives stated by the Panel, the Advisory Council constituted a Standing Scientific Library and Technical Information Committee charged, *inter alia*, with co-ordinating the development of scientific libraries as a whole, and considering in greater detail the parts to be played by individual libraries. This Committee eventually reported on the needs of the national library of science and invention which is to form part of the new Science Centre, and in its fourth report, in July 1951, the Advisory Council referred to the action which had been taken in consequence of the Government's announcement of November 21, 1950. It was indicated that the President of the Board of Trade had agreed that the Patent Office Library should be expanded to form the national reference library of science and invention, and that it would continue to serve the needs of the Patent Office. It would cover the whole field of science and would be supported by the specialized libraries of the learned societies. The areas of its responsibility had been agreed with the Research Councils and with the Government Departments principally concerned. Moreover, in conformity with the proposal that the Library should not contain any scientific literature more than about fifty years old, material no longer of value for current work was to be pruned in consultation with the British Museum.

The advisory Council further emphasized that the Library would serve industrial scientists and all those concerned with research and technical development, and would be adjacent to the Department of Scientific and Industrial Research, so that more detailed information services would be available for users. The Advisory Council stated that the Lord President of the Council, Viscount Addison, had approved the report, which had been forwarded to the Ministry of Works for preliminary planning in connexion with the Science Centre.

It is therefore clear that the planning and discussion of the proposed Science Centre had made considerable progress. Yet on December 17 last in the House of Commons, the Minister of Works stated that the scheme has been postponed. Sir Wavell Wakefield had inquired as to the present position with regard to the Science Centre, and whether it was intended that the necessary buildings should be erected on the South Bank site. Mr. Eccles replied that the planning of the Science Centre had had to be deferred in view of the need for economies, and that when the economic situation improved it was hoped to lease a site on the South Bank immediately below Waterloo Bridge.

That this bland reply was received in the House of Commons apparently without protest demonstrates how far not merely the Government but also the House of Commons is from any real appreciation of the importance of science and technology in the national economy, or of the conditions in which both science and technology are nurtured. It is disheartening enough that once again the plans and hopes of a decade should be jettisoned without result; nor can that jettisoning be regarded as other than waste and false economy. For it must be noted that Mr. Eccles stated expressly that the planning itself—not the actual construction—had been deferred.

That in itself is discouraging enough, for no one who has been associated with what has been done, ever since the Royal Society Scientific Information Conference in 1948, can fail to realize the far-reaching repercussions of such a decision and the frustration which must result in many different fields. The record of disappointments which have attended the efforts of the Royal Society over the past century to obtain a worthy home and adequate accommodation, and which Sir Henry Dale recapitulated more than ten years ago, is well calculated to prejudice any fresh effort. It makes it hard to believe in the sincerity of any fresh government approach "when the economic situation improves".

That, however, is not all. The project for a Science Centre was intended not merely to provide a dignified home for the Royal Society and other scientific societies: it was also intended to further their more efficient and economic functioning. Thus the financial difficulties which threaten the continuation of the Bureau of Chemical Abstracts might have been considerably less acute, and the call for Government assistance much slighter, if indeed made at all. Furthermore, even so far as already elaborated under the Advisory Council for Scientific Policy, the project appears to offer some advantages and savings in the operation of the Department of Scientific and Industrial Research without detriment to its efficiency.

The real objection to the postponement of the scheme is its adverse effect on the advance of science and technology upon which the economic recovery and survival of Great Britain so largely depend. That dependence has been admitted by Government spokesmen and others, who have insisted that the first need is to secure the effective utilization of existing knowledge, and have recognized, too, the dependence of such utilization upon the effective dissemination of scientific and technical information. The proposal for a national reference library of science and technology, which forms an essential part of the scheme, and which was intended to relieve the congested conditions which at present hinder the efficient use of the library of the Chemical Society and others, was a step to that end long overdue.

The Department of Scientific and Industrial Research has already re-orientated its policy so as to encourage the more effective dissemination of both scientific and technical information, and thus made the need for such a central library more urgent. Moreover, while Governments have procrastinated, the outflow of scientific and technical literature throughout the world does not stop but rather increases. Libraries which were overtaxed ten years ago are still more overstrained to-day: conditions and expedients, which could be accepted for a short period while plans for adequate accommodation were being formulated, become intolerable when delay is indefinite.

Now the whole scheme is in abeyance. It may be that economic conditions, on a short-term view, are so serious that immediate action on the scheme is impossible, in spite of its importance for the future of science and technology in Britain. Having proceeded thus far, however, every opportunity must be taken to remind the government of the day of its existence—and of its vital importance.

# A BOTANIST'S QUO VADIS: INTEGRATION OR SPECIALIZATION

## Phylogeny and Morphogenesis

Contemporary Aspects of Botanical Science. By Prof. C. W. Wardlaw. Pp. viii + 536. (London: Macmillan and Co., Ltd., 1952.) 42s. net.

Many of those who belong to the older generation of biologists may recognize in biology at the present time something of the welter of confusion in aims and ideas that marked the similar period after the First World War. It is therefore an appropriate moment to ask whether we are going to witness another transformation in the climate of biological thought similar to that which overtook the biological subjects after 1920. Revolution in techniques is obviously taking place. Will this produce a generation of botanical specialists, or is it possible to offer an idea which will serve to integrate further advances? At such a time it is stimulating to receive a book by an eminent botanist which looks at the present position and attempts to resolve it.

Prof. Wardlaw's central position is that of a morphologist and, as his title indicates, he sees in phylogeny and morphogenesis twin aspects of a unified treatment of plant form which may serve as a focal point for further botanical developments. His detailed consideration of these matters, ranging over a wide field, starts with the comparative study of the phylogeny of ferns and other pteridophytes (as suggestive examples). This leads to a consideration of the morphology and origin of leafy shoots and the questions associated with the origin of a land flora. The antithesis of this comparative treatment is next developed—the idea of causal morphology leading to the developmental study of morphogenesis. Three chapters deal with the influence of genes on the development of form; then come three more chapters devoted to biochemical aspects of this problem. There follows an inquiry into the physical and mathematical considerations involved, and this leads to a survey of experimental studies on morphogenesis in which the author's own work on ferns figures prominently.

The point of view adopted is thus that morphogenetic processes have necessarily a genetical basis. The primary action of genetical factors upon growing cells is held to be biochemical in nature; but simultaneously, and often as a direct consequence, physical factors become operative and are largely involved in the detailed determination of form and structure in the tissues. But because form is regarded as a product of evolution, it follows that the findings of phylogeny and of the comparative method will be of advantage to the morphogenetist, just as enhanced knowledge of morphogenesis must lead to a better understanding of phylogeny.

Prof. Wardlaw thus suggests that, while contemporary botanical science is feeling boldly in a number of directions, this does not mean that its students must necessarily become more specialized and its study more dispersed. He clearly sees the possibility of integrating these diverse lines of advance around the twin subjects of phylogeny and morphogenesis. This is not very far away from the late-Victorian doctrine that the study of evolution should be the main motive underlying biological research, although no doubt the emphasis is now placed differently. In particular, the morphological consequences of this doctrine are restated in modern terminology and in the light of modern work. It is clearly impossible to say how this point of view may represent the future of botany. A majority of present-day students of this subject appear to have a greater interest in the *processes* by which the living organism functions than in its form. For this reason the dynamic aspects of morphogenesis are likely to prove more popular than the comparative. Thus growth and organization, which are essentially dynamic and which we can study as existing processes, are beginning to attract more attention than evolution as the fundamental properties of living organisms. If so, it is around these that it may prove possible to integrate the future of botany, whatever an individual's special field of interest may be. This, at least, might well be an alternative statement of the note on which this book ends.

It would be unusual in a work of this type if the specialist in any section of the vast and diversified field surveyed could not find some point of criticism. It would be unjust to direct attention to these in a short review without being able to survey in much greater detail the wealth of information the book contains. It must suffice to say that such a book has been greatly needed. Its publication will stimulate thought and inquiry in a fundamental field.

W. H. Pearsall

# PREHISTORY IN AFRICA

**Proceedings of the Pan-African Congress on Prehistory, 1947**

Edited by L. S. B. Leakey, assisted by Sonia Cole. Pp. viii+239. (Oxford: Basil Blackwell, 1952.) 35*s*. net.

UNTIL about the second decade of the present century the study of early prehistory was mainly confined to Europe, more particularly to the western regions. Later, as a result of the brilliant researches of a number of prehistorians, the importance of Africa to the subject has been more and more realized. Investigators in all parts of the continent have made discoveries of great interest, and these cannot always be fitted into the narrow framework of the scheme of development created by the prehistorians in western Europe.

Dr. L. S. B. Leakey, a former pupil of the Cambridge school of archæology, fully realized this situation; but the outbreak of the Second World War delayed any action, and it was not until its conclusion that he determined to call a Congress, held in Nairobi in 1947, to discuss the various early archæological problems in the African continent. Maybe it was a pity the Congress was called so soon after the War; if it had been summoned a year, or even two years, later many more prehistorians from many more countries would have been able to attend. When important decisions are to be taken, it is well to have more delegates present than were able to be at Nairobi so soon after the close of hostilities; only now has it been possible to produce the proceedings, and most of the papers appear in a very attenuated form. Shortage of paper and expense were, of course, the reasons.

Roughly speaking, the work of the Congress came under three headings: papers dealing with aspects of geology, general palæontology and climatology; papers on human palæontology; and papers on prehistoric archæology. Obviously, before a stone-age culture can be properly understood, the conditions under which it flourished must be known, and this involves questions of Quaternary geology and palæontology. Prof. C. Arambourg contributes two papers on "African Pleistocene Mammals" and "The Red Beds of the Mediterranean"; and there is a paper, with many diagrams, on "Pleistocene Climate Changes in East Africa" by Dr. E. Nilsson. There are also papers by Abbé H. Breuil, Prof. F. Zeuner and Dr. A. Ruhlmann. The section of the Congress on human palæontology is nowadays perhaps a little out of date, as the study of early man himself and his precursors in Africa has been going ahead by leaps and bounds. But the facts as known at the time are duly set out in a number of papers by the late Dr. R. Broom, Prof. W. E. le Gros Clark, Prof. R. Dart and others. The final section contains papers on various industries and cultures. Dr. Desmond Clark writes on Somaliland; but shortly his book on this interesting region will be published, and we shall have his work there set before us in detail. The problem of the so-called Tumbian culture in the Congo is discussed by Dr. F. Cabu and Dr. Leakey, and there are also, among many other contributions, papers from Dr. B. D. Malan on "The Final Stages of the Middle Stone Age in South Africa" and by Dr. S. A. Huzayyin on the "Upper Palæolithic of Egypt".

The volume is, of course, of first-class importance to any prehistorian interested in Africa. It is only such a pity that factors outside the control of the editors have so delayed its publication. It is to be hoped that the proceedings of the Second Congress, held recently in Algiers, will see the light of day rather more speedily.

MILES BURKITT

# PSYCHOSURGICAL STUDIES AT THE GREYSTONE HOSPITAL

**Psychosurgical Problems**

By the Columbia Greystone Associates, Second Group. Dr. Fred A. Mettler, Editor. Pp. xii+357. (London: Routledge and Kegan Paul, Ltd., 1952.) 42*s*. net.

THIS book is a second report of the work carried out by a research team known as the Columbia Greystone Associates. The first report by this group, called "Selective Partial Ablation of the Frontal Lobes", dealt with various biological, psychiatric and psychological effects of psychosurgery (particularly topectomy) as applied to psychiatric subjects. The present volume reports a similar study into the after-effects of various less commonly employed psychosurgical procedures (notably cortical, venous, ligation and thermocoagulation).

The seventeen chapters of "Psychosurgical Problems" are written by psychiatrists, psychologists, neurologists, physiologists and other experts in various medical fields, whose names are well known within their specialties. Starting with a general survey of the project and a consideration of the special setting within the Greystone Hospital, the writers take up in turn the surgical procedures employed, general medical findings, neurological findings, vestibular functions and, for the remaining two-thirds of the book, psychological studies. All these contributions are clearly written, scholarly and well presented. Nevertheless, the reader is likely to lay down the book with a feeling of disappointment. In the first place, the number of cases included is rather small; including control subjects, we are dealing only with about thirty patients in all. It may be doubted whether such a small number which, it should be remembered, has to be sub-divided again because of the different operations carried out, really justifies such detailed reporting. In the nature of the case, only very gross changes could be expected to exceed reasonable criteria of statistical significance, and such gross changes would scarcely have required the setting-up of such tremendous experimental apparatus.

In the second place, the reader will find that in this study, as in the one preceding it, conclusions are mainly negative; that is to say, the research workers failed to find changes after the operation in the various areas investigated. It is, of course, possible that surgical interference with the frontal lobes has only very slight and negligible effects on personality, but it is doubtful if such a hypothesis would seriously be entertained by most workers familiar with the field.

The dearth of positive findings is much more likely to be due to a fundamental weakness of this whole endeavour. There is no underlying theory according to which investigations were carried out and procedures selected; there does not even seem to have been a set of guiding hypotheses, the disproval of which might have advanced the study of the field.

The Columbia Greystone Associates seem to have proceeded throughout in a spirit of empiricism which selects tests and procedures without the benefit of theory. This must be held responsible for the failure of the whole experiment to give positive results; as A. Petrie has shown in Great Britain, suitable choice of theoretical concepts and the selection of experimental techniques based on such theory can uncover strongly marked changes after psychosurgery.

On the whole, then, we may conclude that while this book is of undoubted interest to the specialist and will be read widely by those professionally interested in psychosurgery, the contribution it makes to scientific knowledge is relatively small.

H. J. Eysenck

## SAND- AND WATER-CULTURE OF PLANTS

### Sand and Water Culture Methods used in the Study of Plant Nutrition

By Dr. E. J. Hewitt. (Commonwealth Bureau of Horticulture and Plantation Crops: Technical Communication No. 22.) Pp. x+241+9 plates. (Farnham Royal: Commonwealth Agricultural Bureaux, 1952.) **42s.**

THE first recorded use of the water-culture method for the growing of plants was that of Woodward, who in 1699 grew potatoes, vetches and mint in water from springs, wells, rain and distillation. Sixty years later Duhamel du Monceau grew tree seedlings in filtered water from the Seine; but it was not until 1804 that the first controlled water-culture experiments were attempted, by De Saussure in France. He was the first to show that nitrates were necessary for growth and that differential absorption of solutes was usual. The method of sand culture was introduced by Boussingault in 1851 and greatly extended by Salm-Horstmar, who, even at that early date, used a technique sufficiently refined to show the essential nature of manganese and iron as well as the 'macronutrients' for plant growth.

Since the time of these early workers, more and more elaborate and precise techniques have been evolved by hundreds of workers in the field of plant nutrition. In the investigation of the roles of the 'micronutrients' or 'trace elements' in plant physiology, and even more in the study of the interrelations of nutrients, small details in the purification of growing-media or nutrient solution, in the preparation of containers, or in the protection of the cultures from chance contamination, may be of vital importance. Any new worker in the field must therefore make himself familiar with the experience of many hundreds before him to be sure that he has missed no point essential to his proposed technique.

In this task Dr. E. J. Hewitt's book will be of quite inestimable value. He has brought together in one volume a prodigious amount of detailed information, critically reviewed, from a literature of some eleven hundred titles. No aspect of the subject escapes minute attention, and the author throws his net wide enough to include even methods for the control of the environment in plant chambers and the design and interpretation of experiments. In the second part of the book, Dr. Hewitt gives a detailed account of the special technique developed at the Long Ashton Research Station, mainly by himself, for large-scale sand culture in pots, an illustration of the perfection achieved by learning from the experience of others.

Few reviews of literature have been so exhaustive, informative and valuable as this, and the author and the Commonwealth Bureau are to be congratulated on the production of a book which will save research workers many weary hours of searching through original papers.

R. H. Stoughton

## A PSYCHIATRIST'S CREDO

### Speaking of Man

By Dr. Abraham Myerson. Pp. 255. (London: Martin Secker and Warburg, Ltd., 1952.) 15s. net.

THIS is not a serious scientific contribution but a collection of essays loosely linked together, describing the author's views on life and mankind. The style varies and is sometimes grave and erudite, and at others slangy and cynical. Yet invariably the personality of the author permeates the whole and shows him as a witty cynic.

Abraham Myerson was a New England neuropsychiatrist who was a student of Morton Prince and became his life-long friend. He was later elected assistant professor of neurology at Tufts Medical School, and after three years was made professor. Warren Stearns, a former dean of the School, said that the large number of students who specialized in neurology did so because of the popularity of Myerson's teaching.

The most important work which he performed was his investigation into the inheritance of mental diseases and upon which he published one of his numerous books. He did not limit himself to one section of psychiatry, however; but his endless curiosity compelled him to study everything from the neuroses of the nervous housewife to sleeping and waking mechanisms.

It is surprising that Myerson should have written so vigorously in this book when one considers that a great deal of it was produced when he was very near death from heart-block. The chapter headings show the type of material upon which he writes: on the worth of living; my father and I discuss matters; my prejudices and prepossessions; woman, the authorities' scapegoat; the liabilities of language; heredity and environment; the great unlearning; the low-down on authorities, including psychiatrists; genius; sterilization; desire and mental health; body and mind; concerning intelligence; etc.

As these essays show, Myerson was essentially broad-minded. It is said that, although he did not believe in psychoanalysis, he made no objection when his son wished to study it. This appears in his attitude to psychiatry, demonstrated by two of his aphorisms: "The physiological approach to the neuroses does not exclude nor minimise the importance of a complete understanding of the psychological life of the individual"; and "Scientific psychiatry should be sceptical, humble, and experimental".

Those who read this book will enjoy the distilled wisdom and wit of one who regarded everything with scepticism, yet who was strongly on the side of truth and who hated pompous inaccuracies.

Clifford Allen

### The Terpenes

By Sir John Simonsen and Dr. D. H. R. Barton. Second edition. Vol. 3: The Sesquiterpenes, Diterpenes and their Derivatives. With addenda to Vols. 1 and 2, by Sir John Simonsen and Dr. L. N. Owen. Pp. xi+579. (Cambridge: At the University Press, 1952.) 50*s.* net.

THE publication of this volume brings to a successful conclusion the arduous task of issuing a second edition of a work that has become a classic in terpene chemistry (see *Nature*, 160, 384; 1947). The vigorous growth of this field of organic chemistry since 1931–32, the date of the original edition, is reflected in the expansion of the second edition from two to three volumes, totalling some seventeen hundred pages. The subject-matter of the original second volume has now been conveniently sub-divided into "Dicyclic Terpenes" (Vol. 2) and "Sesquiterpenes and Diterpenes" (Vol. 3). In the preparation of the new edition Sir John Simonsen has been fortunate in enlisting the general help of Dr. L. N. Owen and Dr. D. H. R. Barton, together with special aid from Prof. W. Cocker in preparing an account of santonin.

The third volume incorporates a review of the important literature up to 1949, and contains some references to 1950; moreover, it includes addenda bringing the matter of the first two volumes up to date. Among the interesting subjects dealt with in this supplement are recent studies on the *iso*propenyl–*iso*propylidene controversy, and a review of the evidence which shows that irone must now be recognized as 6-methyl-ionone, capable of existing in α-, β- and γ-forms, each corresponding to several stereoisomeric modifications. That terpene chemistry still has much to offer to the investigator is shown *inter alia* by the current researches of Ruzicka and his collaborators at Zurich and also by the interesting lists given in the work here under review of compounds of various types, the constitutions of which still await elucidation.

The attractive format and the remarkably clear type and formulæ of the first edition have been reproduced in the new publication. From every point of view this is a major work of the first class, which is certain to receive the warm welcome it deserves.

John Read

### Linear Transformations in *n*-Dimensional Vector Space

An Introduction to the Theory of Hilbert Space. By Prof. H. L. Hamburger and M. E. Grimshaw. Pp. x+195. (Cambridge: At the University Press, 1951.) 25*s.* net.

THE concept of space of infinitely many dimensions, effectively introduced about fifty years ago by Hilbert in connexion with integral equations, co-ordinates and elucidates many of the problems in mathematics and mathematical physics in which linear operators are involved. Prof. H. L. Hamburger and Miss M. E. Grimshaw have provided a useful prolegomenon to this doctrine; they deal with analogous problems in *n*-dimensional linear space, particularly the study of canonical forms of transformations, but they choose, wherever possible, methods which will also serve for Hilbert space. The arguments are crisp but austere, even in this simpler field, and they are mainly algebraic, although Hilbert's variational method for the eigen-values of a Hermitian form is included. Recently obtained inequalities due to Aronszajn indicate an application to the numerical calculation of eigen-values; and the reduction to canonical form of a pencil of operators is illustrated by a detailed study of the familiar dynamical problem of small oscillations.

The topic is abstract, and the arguments, even when geometrical language is used, demand close attention; but the precision with which these powerful methods operate is worth an effort to acquire. It is to be hoped that the authors will produce a sequel in which the methods are shown at work in Hilbert space.

### The Higher Arithmetic

An Introduction to the Theory of Numbers. By Prof. H. Davenport. Pp. 172. (London: Hutchinson's Scientific Library, 1952.) 8*s.* 6*d.* net.

MOST mathematicians, amateur and professional, find the theory of numbers fascinating. Prof. H. Davenport, in his concise, self-contained account, deals with factorization and the primes, congruences, quadratic residues, continued fractions, sums of squares, quadratic forms, and some Diophantine equations. His complete mastery of the field has helped him to give a clear, forward-looking and thoroughly up-to-date exposition. In number theory, results may often be easy to guess but difficult to prove, yet guess-work without proof is almost worthless. Davenport's rigour of demonstration, demanded by the nature of the subject, is always lucid, but it requires the reader's close co-operation, often with pencil and paper; the well-chosen numerical examples, with which the author illuminates practically every step, help to concentrate attention. Little previous knowledge is assumed, but by sticking fairly closely to main themes, the author brings his reader near to the present bounds of knowledge and indicates some of the likely lines for further progress. The novice who wishes to pay his respects to the 'Queen of Mathematics' will be wise to choose Prof. Davenport's presentation.

### Botany

By Prof. Carl L. Wilson. Pp. xi+483. (New York: The Dryden Press, 1952.) 6.10 dollars.

THIS attractive book, intended primarily as an introduction to botany for students in American colleges, succeeds admirably in presenting the elements of the subject in a most agreeable and refreshing manner. The first half of the book follows the normal pattern of botanical text-books by dealing with the structure and physiology of the higher plants. It is noteworthy to find such topics as vegetative reproduction, erosion, food poisoning, hay fever plants, growth substances, viruses and antibiotics introduced in this elementary treatment. The later chapters cover a wide survey of the whole plant kingdom with outline classifications of the various groups and details of significant life-histories. The account of early land plants and their evolution is particularly well written and illustrated.

Each chapter is prefaced with a brief and sometimes historical introduction to the contents and concludes with a useful summary. As may be expected, the examples selected for study are those readily available to American students, and the predominant emphasis is on the vegetation of North America. In spite of this, Prof. Wilson has produced a most stimulating text-book which should be read and enjoyed by students and laymen alike.

There are many photographic illustrations, and special praise must be given to Dr. Hannah Croasdale for the clear and convincing diagrams and figures.

# DISLOCATIONS AND THE THEORY OF SOLIDS*

By Prof. N. F. MOTT, F.R.S.
H. H. Wills Physical Laboratory, University of Bristol

A DISLOCATION is the name given to a particular type of defect in a crystalline solid. The concept was introduced into physics by Taylor[1] and others[2,3] in 1934 in a first attempt to devise a mechanism on the atomic scale to describe plastic flow. Since the Second World War, the theory has developed rapidly, and, apart from its applications to flow of crystalline materials and to strain-hardening, it is of importance for the understanding of crystal growth, grain boundaries and also chemical reactions in solids. The aim of this article is to outline these developments; for a description of some of the properties of dislocations the reader should consult the reviews of, for example, Cottrell[4], Nabarro[5] and Mott[6,7].

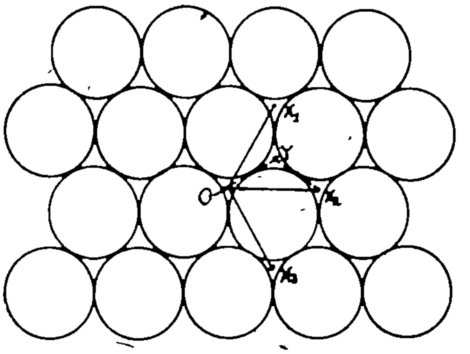

Fig. 1. Close-packed plane of a face-centred or hexagonal crystal, showing the three possible Burgers vectors, $OX_1$, $OX_2$, $OX_3$. $OY$ represents the vector for a 'half dislocation'

A dislocation is a line discontinuity which must either form a closed loop or end on the surface of a crystal. If it lies in a slip plane, it can be defined as the line separating the part of the material that has slipped from that which has not. A dislocation is characterized by its Burgers vector, which represents the distance through which the slip has occurred. Thus, for a close-packed cubic slipping on the (111) planes, there are three possible Burgers vectors, as shown in Fig. 1. Figs. 2 and 3 show the two main types of dislocation, the edge and screw, though intermediate and other types are possible. In the edge type the Burgers vector is perpendicular to the dislocation line, which means that the dislocation line can move only in the plane containing both, whereas the screw, for which the two are parallel, can switch from one plane to another. This has important consequences for the theory of cross-slip (cf. ref. 7).

It will be seen from Figs. 2 and 3 that the crystals are shown as having steps on the surface, and that where a screw dislocation meets the surface a step necessarily ends. Now, on straining a metal crystal or a grain of a polycrystalline metal, steps of just this type are formed, which are frequently observed to terminate. These steps are called 'slip lines', and their height is usually about a thousand lattice spacings, though recent work has shown that steps of much smaller height can be formed[8], especially in creep[9], and by using special techniques slip lines one lattice parameter high have recently been observed on silver crystals[10]. (Steps of much greater height have been shown[11-13] to consist of 'clusters' of elementary lines close together.) So we must distinguish between the elementary (screw) dislocations which terminate at the end of a step one lattice parameter high, and the strong dislocations or groups of 'piled-up' dislocations[14] which mark the end of a slip line of the normal type.

Any theory of plastic flow and of the formation of slip lines starts from the assumption that the annealed material contains dislocations, and it is first necessary to review the evidence for this. First of all, any evidence that a crystal has a mosaic structure can now be interpreted in this sense; a mosaic boundary—or boundary of a polygonized cell—can be analysed into a row of dislocations. This is well shown by the bubble rafts developed by Bragg and by Lomer and Nye[15], of which an example is shown in Fig. 4. Arising out of this concept, many calculations have been made[16,17] of the energies of grain boundaries and mosaic boundaries as a function of the angle between the grains. This approach gives values in very good agreement with experiment, even for angles such that, as Fig. 4 shows, the analysis into dislocations is no longer valid.

Secondly, there is the now well-known evidence from observations of crystal growth (for a review see ref. 18). When crystals are formed from vapours or from solution, they frequently grow by the rotation of a step, such as that of Fig. 3, about the point $A$ where it terminates on a screw dislocation. This mechanism was first proposed by Frank, who showed that the join of the step to the surface would not remain straight but would curl up into a spiral. Since then, spirals have been observed on a large number of crystals[18], and in the case of cadmium iodide growing from solution it has been possible to prepare a film showing the rotation. On cadmium iodide the step—now called a growth step—is several hundred lattice parameters high and, like slip bands on solids, is easily visible under the microscope. On paraffin crystals grown from solution, the height is the length of the paraffin molecule, and, after gold shadowing, the steps are visible with the electron microscope by direct transmission. The much smaller monomolecular steps on beryl, magnesium[19] and silver[10] are visible by means of the optical microscope only because of the 'decoration' of the line of the step by a row of etch pits in the case of beryl[20], and in the case of the metals by a ridge, probably of sulphide, which forms when the metal surface is left for some hours in the presence of 'Plasticine'. Growth steps are thus reactive regions and should be of importance in surface chemistry.

Some of the recent successes of the work on crystal growth have been: the explanation of polytypism on silicon carbide[21]; the prediction that, when growth is by the rotation of a step of considerable height, the centre of the screw dislocation would be a

cylindrical hole, and also the observation[12] of such a hole in cadmium iodide; and the observation on beryl[13], on paraffins (cf. Fig. 6) and on metals[10] of patterns of the types of Fig. 5. In the case of these observations, they show that, after growth has finished, the screw dislocation on which the growth spiral was locked has moved. They thus give direct evidence that dislocations can move, and represent, to my knowledge, the first observation of slip lines of height equal to one atomic or molecular spacing.

The whole phenomenon of crystal growth gives some clue as to why crystals contain dislocations, since according to this model it is impossible for a crystal to grow unless it contains at least one screw dislocation, which may be formed when the crystal nucleates on some foreign body. It is by no means suggested, however, that this is the only origin of dislocations. Seitz[14] has suggested that they may form by the condensation of vacant lattice-sites as a crystal is cooled, and Teghtsoonian and Chalmers[15] have shown that something of the sort occurs when metals grow from the melt. Also, it is not believed impossible in principle to prepare a crystal without dislocations; Fig. 6 shows a paraffin crystal prepared and photographed by Dawson and Vand which has grown on two screw dislocations of opposite sign; these, after growth was complete, have moved together under their mutual attraction and annihilated one another. This crystal contains at any rate no screw dislocations.

Perhaps the most direct evidence of the existence of dislocations comes from the recent success of J. W. Mitchell[16] in getting photolytic silver to separate out along dislocation lines in a transparent crystal, silver bromide, which has been slightly strained and then annealed. One of his photographs is shown in Fig. 7. The hexagonal form of the dislocation network was predicted two years earlier, following a suggestion by Frank, in a lecture by me[7]. It arises because, as Fig. 1 shows, the three possible Burgers vectors in the face-centred cubic add up to zero, so that three dislocations can meet in a point. This work is at present in its infancy, and promises to give much valuable information.

We turn now to the phenomenon for the description of which dislocations were invented—namely, plastic deformation of crystalline solids. The first two questions to be answered in this field are: Why is slip usually concentrated on relatively few active planes, giving the visible slip lines on the surface, and why do metal crystals deform for stresses so much below the theoretical stress? Both questions are answered by the model of Frank and Read[17], of which several further accounts have appeared in the literature[5–7]. These workers show that a dislocation line which is terminated at its two ends—for example, in the way in which the elements of the network of Fig. 7 are terminated—will, when the material is stressed, produce an indefinite number of 'dislocation rings' which can spread out to the surface of the crystal, there producing a slip line. Thus any of the segments of the network shown in Fig. 7 is capable of acting as one of these 'Frank–Read sources'. If $l$ is the length of one of the segments, the stress required to produce slip is shown to be $Gb/l$, where $G$ is the shear modulus of the material and $b$ the Burgers vector. Values of $l$ of the order $10^{-4}$ cm. give agreement with experiment for the yield stress of single crystals. This is of the order of the distance usually assumed between dislocations or mosaic boundaries.

In materials other than pure annealed metals the resistance to flow is due to three causes as follows. (1) The locking effect of impurities which diffuse to the dislocations and are trapped there[18,19] (Cottrell locking). This effect is particularly marked in the case of interstitial impurities in body-centred metals. In many cases it leads to a sharp but temperature-dependent yield point and is probably connected with the phenomenon of notch brittleness. (2) Internal strains due to precipitates or 'Preston–Guinier zones'. These strains impede the movement of dislocations. Much less dependence on temperature is expected[20] than for Cottrell locking. (3) Internal strains due to cold working.

When a cubic metal is strained at a fairly low temperature, the number of slip-lines observed

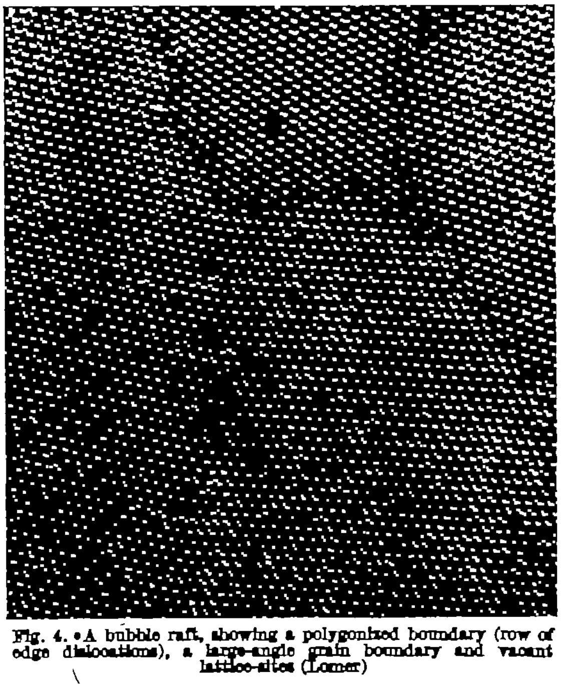

Fig. 4. A bubble raft, showing a polygonized boundary (row of edge dislocations), a large-angle grain boundary and vacant lattice-sites (Lomer)

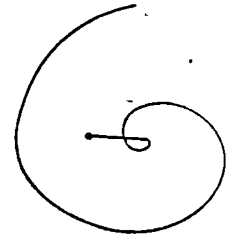

Fig. 5. The type of step on the surface of a crystal which occurs when the screw dislocation has moved after growth has finished

increases, but the amount of slip on each does not. Both I[7] and Fisher, Hart and Pry[31] have deduced from this that the operation of the Frank–Read source is a dynamic process, the dislocations moving with a speed near that of sound and their own momentum keeping the process going until about a thousand dislocation rings are produced; the stress due to these dislocations then stops the action of the source. With this model the formation of a slip line takes about a microsecond (1,000 $l/c$, where $c$ is the velocity of sound), after which its height does not increase, although its length may (Chen and Pond[32]).

When a slip line terminates within a solid, there must be present, as already emphasized, regions of very high strain, where about a thousand dislocations are piled up together. The properties of these groups have been worked out by Eshelby, Frank and Nabarro[14]. According to Stroh[33] they contain the main part of the stored energy. I have ascribed the work-hardening of cubic metals to the strains produced by these groups[6], and my model is similar to that of Taylor[1], except in the following respects: the random internal strain is due to a relatively small number of strong groups instead of a large number of isolated dislocations; and a mechanism is proposed for locking the groups in position. This is based on the demonstration by Lomer[34] and Cottrell[35] that, in the face-centred cubic, dislocations moving on octahedral planes inclined at an angle to each other can combine to form the so-called sessile or immobile dislocations. This observation is supported by the observation by Andrade and Henderson[36] and Lücke and Lange[37] of the phenomenon of easy glide. In good single crystals suitably oriented the dislocations pass out of the solid and no hardening or X-ray asterisms occur; but a condition is that slip should be on one plane only. As soon as sessile dislocations are formed, dislocations are trapped and hardening results.

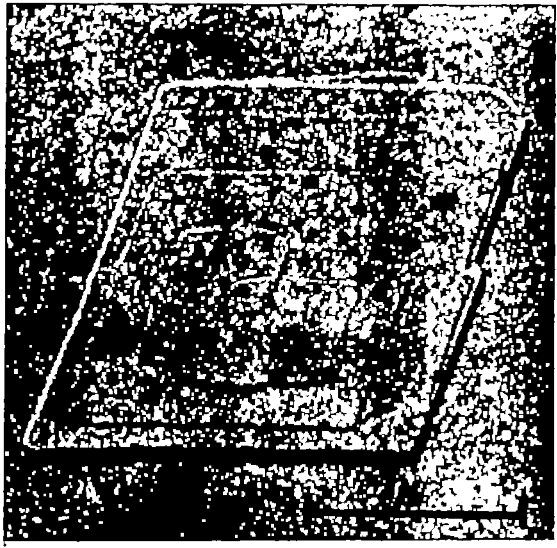

Fig. 6. Electron micrograph of a paraffin crystal, which has grown through the rotation of spirals about two screw dislocations of opposite hand. After growth has finished, the screws have moved together and annihilated each other (Dawson and Vand)

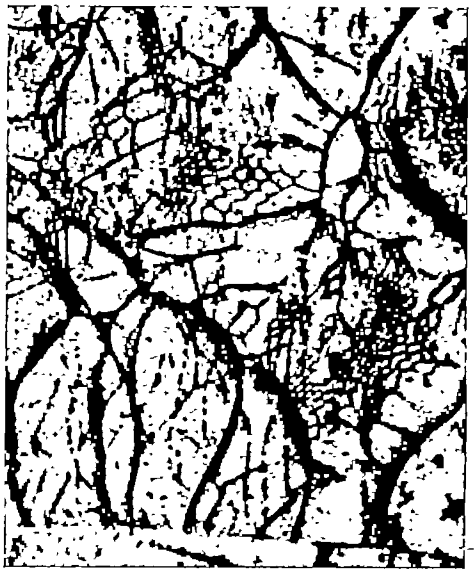

Fig. 7. Dislocation networks in silver bromide. These are formed by a small strain followed by an anneal, and are made visible by exposure to light, which precipitates silver along the dislocation lines (J. W. Mitchell)

Thermal recovery is to be ascribed to the break-up of the piled-up groups of dislocations. To escape from such a group, edge dislocations must 'climb' or leave their slip planes. To do this they must absorb or give off vacant lattice-sites, and the process is thus associated with self-diffusion, which also is believed to occur through the agency of vacancies. Owing to the very great stresses in the piled-up groups, however, the activation energy for 'climb' decreases with increased cold work, and may be less than for self-diffusion[7]. The sensitiveness of recovery to purity is to be explained by the ease with which diffusion of an impurity to the piled-up groups may diminish these stresses.

After escaping from the piled-up groups, some of the dislocations of opposite sign may annihilate each other, but most form polygon boundaries. This must be thought of as a secondary process; the essential process for recovery is the dissolution of the piled-up groups.

The vacancies normally responsible for recovery and for self-diffusion are those formed by thermal agitation. There is now much evidence, however, that cold work itself produces vacancies[38–40]. To this may be described the increased rate of diffusion in some alloys which can be observed after cold work, just as after bombardment by fast particles[41], which also produces vacancies. Following Brown[12], I have suggested[6] that vacancies formed near a slip line can cause some sort of local annealing, and so account for the fact, first pointed out by Heidenreich and Shockley[11] and by Brown[12,13], that, after the formation of one elementary slip line, if the temperature is not too low, others are formed very near it, often at a distance difficult to separate with the optical microscope.

In conclusion, it may be said that there is now strong evidence for the existence of dislocations, and powerful experimental methods exist for studying their properties. With the help of this concept, it has been possible to account for some of the most important facts about plastic flow, though much remains to be done.

# CHINESE SCIENCE REVISITED (I)

By Dr. JOSEPH NEEDHAM, F.R.S.

DURING the period of the Second World War I had the good fortune to be sent to China with the mission of rendering all assistance possible to Chinese science and technology in its difficult position of blockade. At that time, Chinese scientists were working under many difficulties and with great devotion in the remoter parts of the country, where institutions of learning and production had been set up out of reach of the Japanese. Last year I was able to take advantage of another invitation which enabled me to spend the summer in China. Since circumstances have of late impeded the flow of news between the two countries, it may well be that some information concerning Chinese science and scientists to-day will be welcome to readers of *Nature*.

After twenty-one years of useful life, the Chinese National Academy (Academia Sinica) was re-founded on November 1, 1949, following the assumption of power by the present Government of the Republic. It is placed directly under the Cultural and Educational Commission of the Administrative Council of the Central People's Government, one of the five Commissions stemming directly from the Council or cabinet. The president of the Academy, Dr. Kuo Mo-Jo, one of China's leading historical archæologists, is also chairman of this Commission and one of the Vice-Premiers. Similarly, the vice-chairman of the Commission is also one of the vice-presidents of the Academy, Mr. Ch'en Po-Ta. The other vice-presidents are also well-known men: Dr. Li Ssu-Kuang (geology); Dr. T'ao Mêng-Ho (sociology); Dr. Chu K'o-Chen (meteorology); and Dr. Wu Yu-Hsün (physics).

The recognition of science as basic to the life of the nation is written into the Common Programme of the Chinese People's Political Consultative Conference. Art. 41 states that the education of the country shall be "new and democratic—i.e. national, scientific and popular". Art. 43 says that "efforts shall be made to develop the natural sciences in order to serve industrial, agricultural, and national defence construction. Scientific discoveries and inventions shall be encouraged and rewarded, and scientific knowledge shall be disseminated among the people". The Academy now works along lines which are the consequences of these conceptions and in harmony with the general ideals of the Government. Science is recognized to have close connexions with the needs of the people, and a great effort has been made to overcome the planlessness of former days. While the main task of the Academy is scientific research as such, it gives much assistance in the training of technical personnel. As a government institution, moreover, it advises government departments on scientific matters, and renders assistance in construction works which are proceeding all over the country.

From the beginning of its life, the Academy possessed central research institutes of its own, and was never a purely deliberative and publishing body. But it had to contend with many difficulties. While the greatest of these was the lack of funds in Kuomintang times, it had also in those days to compete with other almost parallel organizations, notably the National Peiping Academy, founded in 1929 largely by students who had returned from France. A re-organization was long overdue, and this has been effected thoroughly since 1949. The two former institutes of physics, for example, were amalgamated and have re-appeared with clearly differentiated spheres of work, so that one is now concerned with subjects such as nuclear physics and cosmic rays, whereas the other deals with the physics of solids and optical research. Formerly, there were in Shanghai and Peking five separate biological research institutes with overlapping and uncoordinated fields of work. These have now been re-organized into three different institutes, each with its own responsibilities.

The following is a list of the institutes:

Institute of Modern History, Peking.
Institute of Archæology (including Medieval History), Peking.
Institute of Linguistics and Philology, Peking.
Institute of Social Researches, Nanking.
  Sub-Department of Social Researches, Peking.
Institute of Mathematics, Peking.

Institute of Modern Physics (nuclear, cosmic rays, etc.), Peking.
Institute of Applied Physics (solids, optics, etc.), Peking.
Institute of Physical Chemistry, Shanghai.
Institute of Organic Chemistry, Shanghai.
  Laboratory of Materia Medica, Shanghai.
Institute of Physiology and Biochemistry, Shanghai.
Institute of Experimental Biology, Shanghai.
  Laboratory of Developmental Physiology, Shanghai.
  Laboratory of Plant Physiology, Shanghai.
  Laboratory of Entomology, Peking.
Institute of Hydrobiology, Shanghai.
  Marine Biological Laboratory, Tsingtao.
  Taihu Limnological Laboratory, Wusih.
  Marine Biological Station, Amoy.
Institute of Systematic Botany, Peking.
  East China Botanical Station, Nanking.
  Lushan Botanical Station (Chiangsi), Lushan
  Northwest China Botanical Station (Shensi), Wukung.
  Southwest China Botanical Station (Yunnan), Kunming.
Institute of Genetics and Plant Breeding, Peking.
Institute of Geology, Nanking.
  Laboratory of Pedology, Nanking.
Institute of Palæontology, Nanking.
  Laboratory of Cænozoic Research and Vertebrate Palæontology, Peking.
Institute of Geophysics and Meteorology, Nanking.
  Geophysical Experiment Station, Peking.
  Geophysical Experiment Station, Shanghai.
Institute of Astronomy, Purple Mountain Observatory, Nanking.
  Astronomical Observatory, Hsu-Chia-Wei (Zikawei), Shanghai.
  Astronomical Observatory, Fêng-Huang-Shan, Kunming.
Institute of Ceramics and Metallurgy, Shanghai.
  Metallurgical Experiment Station, Kunming.
Institute of Metal Research, Peking.
Institute of Psychology, Peking.
Institute of Geography and Cartography, Nanking.
Bureau of Scientific Instruments (Preparatory), Peking.
Committee of Zoological Taxonomy, Peking.

Besides the research activities of the staff of the above institutes, the National Academy fulfils many other responsibilities. Its Bureau of Publications edits about ten scientific journals on behalf of the Academy itself, and a further twenty on behalf of the various societies, such as the Chinese Mathematical and Geographical Societies. The Library of the Academy has been re-organized, and a greater measure of centralization has been introduced; but separate departmental reference libraries in each institute continue, and last summer I was impressed by the amplitude of some of these, even in subsidiary laboratories. The translation of modern scientific terms into Chinese and the acceptance of standard equivalents has been an important problem for more than half a century. Before the end of the Ch'ing Dynasty, Yen Fu, the translator of Huxley and Spencer, was placed in charge of a 'Bureau of Terms', and this was expanded during the Kuomintang period as the 'Kuo Li Pien I Kuan', but its results did not meet the need. This work is now under the direction of the Academy, and is being rapidly pushed forward, with the consultative help of many hundreds of scientific workers from other organizations. A new development is the Bureau of Scientific Instruments, which makes apparatus needed for particular research projects, and is embarking on the production of high-precision instruments unobtainable on the market.

The leading technical body of the Academy is the Council, which is composed of twenty-six members. Its function is to handle the scientific aspect of all important problems. It consists of Ch'en Yin-Ko (history; formerly professor-designate of Chinese at Oxford), Chiang Li-Fu (mathematics), Y. C. Ma (economics), Wu Yu-Chang (philology), Hou Tê-Pang (chemistry), C. C. Chang (physiology), Ping Chi (zoology), Fan Wên-Lan (history), Chou P'ei-Yuan (theoretical mechanics), Ch'ien San-Ch'iang (Tsien San-Tsiang) (nuclear physics), C. C. Yang (palæontology), and so on. Contributory to it are the committees of specialists, corresponding roughly in number to the institutes mentioned above, but composed of scientific men drawn from universities and government departments as well as those who work in the National Academy itself.

The elaborate planning and re-organization in Academia Sinica has been paralleled by great changes in the universities. So far, this affects mainly Peking and Shanghai, where formerly there were many different universities, each with different origins and traditions. In Peking there were (besides smaller and less important ones) three great foundations: Peking University (*Pei Ta*), always a State institution; Yenching University, a missionary university; and Ch'ing-Hua University, based on the returned American Boxer Indemnity funds. It used to be said that the first of these corresponded in spirit to Oxford and the third to Cambridge; but in any event the spirit of separatism no longer corresponded with the urgent needs for social efficiency recognized to-day. In the formation of a single university analogous to the University of London, the humanistic subjects are being concentrated in Pei Ta, the applied sciences and engineering in Ch'ing-Hua Ta, and the pure sciences in Yenching (which will cease to exist as an independent university). So great is the emphasis upon geology and the importance of expanding the Geological Survey for the full use of China's mineral wealth that a new teaching institution for geology and mining will be created, based on the amalgamated geological departments of all the former universities.

Of course, the description of science in Academia Sinica and in the universities is only part of the story. Vast and elaborate research facilities have been set up under the Ministry of Health, a body which has the same governmental status as the National Academy. Apart from the National Institute of Medical Research, located mostly in Peking, there is the National Institute of Biological Products, an expansion of the former institutes which manufactured vaccines and sera. It now produces these on a far greater scale than formerly, but adds therapeutic hormone preparations and is beginning to make antibiotics on a mass scale. An immense production of modern insecticides is also carried out in the New China; but this is done mostly by firms in cities other than Peking. The production of vaccines by the National Institute of Biological Products and its seven subsidiary factories is still under the direction of that admirable bacteriologist T'ang Fei-Fên, to whose work I referred in *Nature* in 1943. Among its more interesting new developments is the production of a vaccine for Chinese summer–autumn encephalitis using mouse brains.

So far, there has been little or no realization in Europe of the extraordinary progress in public health which the Government has been able to achieve. In the cities and villages there has been a universal campaign against flies, mosquitoes, and other noxious insects, so that Peking, for example, has become freer from flies than most European cities. Thirty-five million rats were killed in north-east China in 1951, and another ten million in the first months of 1952. Formerly, vaccination was infrequent, the largest number of persons vaccinated in any one year being 7·3 million (1946); but since 1949, 307 million (more than half the total population) have been vaccinated. Infantile and maternal mortality have been reduced by a half since 1949. A very interesting development has been the mobilization of the old-fashioned practitioners who follow the traditional system of Chinese medicine; they have been instructed sufficiently in modern medicine to enable them to play a valuable part as inoculators, dressers and givers of first-aid who can deal with minor complaints. Midwives have also been systematically re-educated. The health-education movement, in which all possible methods of publicity are employed, and in which every member of the community participates, is almost unprecedented in history, and constitutes the active execution of measures formerly vainly urged by successive international health organizations. It reaches into the remotest corners of the country.

Naturally, all this costs money, but it is not spared. For scientific research institutes as a whole, the budget for 1952 was ten times that of any year in the Kuomintang period, and for 1953 the four-fold expansion planned will bring it to no less than forty times. Thinking of former conditions, I asked last summer when visiting the Laboratory of Entomology of the Academy how many research workers there were, perhaps a dozen or so; and received the reply that they had more than fifty, though quite a number were away on field expeditions.

The effectiveness of collaborative scientific work is also much greater than before. Dr. Li Ssu-Kuang told me that whereas, under the Kuomintang, meetings of scientists could scarcely ever do more than pass resolutions which were never executed, the atmosphere in the New China is much more practical. For example, at the beginning of 1950 a conference of geologists in Peking took decisions concerning field-work for a number of units, and, before six weeks were out, more than eighty geologists were on the way to the north-east, the north-west and central China, to study the structural geology of the areas and to search for iron, coal, oil and non-ferrous metals. The greatest importance is attached to the geological sciences as vital for the development of China, and in August 1952 the Geological Survey was raised to the status and title of a Ministry, with Li Ssu-Kuang (J. S. Lee) as minister. There can be no other nation where the sciences of the earth are so highly regarded.

The close union between science and the people in New China is a fact which must impress every Western visitor who spends some months in the country. Perhaps by the very fact that the standard of their life was formerly so low, they look to science and technology as one of the great forces able to lead them into a state of freedom from poverty, disease and want. Chinese scientific workers are now inspired by this faith and trust. Moreover, they are given the means to respond to it. Dr. Li himself has written: "In the situation which has arisen with the victory of the Chinese people's revolution, it will readily be understood that science is no longer looked upon as an esoteric activity reserved for a leisure class, but as a public enterprise to be shared by all people, who instead of being reticent as formerly, now conscious of what they need, raise their voices in positive demands in every walk of life. It can now be said that in every sphere, the people will accept nothing that is mechanically imposed on them. They are determined to make their own choice in matters of policy, a choice which demands knowledge and the scientific outlook".

# OBITUARIES

## Sir Charles Arden-Close, K.B.E., C.B., C.M.G., F.R.S.

Sir Charles Frederick Arden-Close, who died at Winchester on December 19, was born in Jersey on August 10, 1865. He was the eldest son of Major-General Frederick Close, of Shanklin, Isle of Wight, and took the name of Arden-Close in 1938, in compliance with the terms of a bequest.

Commissioned in the Royal Engineers on July 5, 1884, Close served first at Gibraltar, and later with the R.E. Balloon Detachment. In 1888 he was ordered to India, and, next year, joined the Survey of India, gaining in that service a varied experience of practical surveying which he put to good use in later years.

In 1893 Close returned to England, and, two years later, was placed in charge of the survey of the Nigeria–Kamerun boundary. After this he joined the Ordnance Survey in Great Britain, and in 1898 was appointed British Commissioner on the Tanganyika–Nyasaland Boundary Commission. Having completed this work, he returned to the Ordnance Survey, and, in 1900, was ordered to South Africa in charge of a small R.E. survey detachment. He contracted enteric fever, however, and soon had to return to England, rejoining the Ordnance Survey as soon as his health had been restored.

In 1902 Close was appointed instructor in surveying at the School of Military Engineering, Chatham, and, while there, prepared his well-known "Text-Book of Topographical Surveying", which quickly became, and has remained ever since, the standard work on the subject throughout the British Commonwealth.

In 1905, he became chief of the Geographical Section of the General Staff at the War Office, and in that capacity played a prominent part in securing the establishment of the Colonial Survey Committee, and in drawing up the working rules for the production of the Carte Internationale du Monde au Millionième at the London Conference of 1909.

In 1911 Close was appointed director-general of the Ordnance Survey, holding this appointment throughout the First World War. Naturally, the War interfered with the civil work of the Survey, but the department sent a detachment to France in 1918, and printed enormous numbers of maps for the armies in France and elsewhere.

Sir Charles retired in 1922, but continued to devote himself to geographical work and study. He became president of many geographical organizations, and, with his wide knowledge and dignified yet genial personality, filled these offices with unusual distinction and success. He was president of the International Union of Geography during 1934–38, president of the Royal Geographical Society during 1927–30, president of the Geographical Association in 1927, and also, for many years, chairman of the Palestine Exploration Fund.

Sir Charles married, in 1913, a daughter of Mr. Thomas Percival, of Shanklin, and had two sons and a daughter. He was the recipient of many honours and distinctions. He was made a C.M.G. in 1898, a C.B. in 1916, a K.B.E. in 1918, F.R.S. in 1919, and he received an honorary Sc.D., Cambridge, in 1928. In 1914 he gave the Halley Lecture at Oxford, and, in 1927, was awarded the Victoria Medal of the Royal Geographical Society.

M. N. MacLeod

## Dr. J. T. Edwards

Dr. J. T. Edwards, who died on November 7, made noteworthy contributions to veterinary science. He had a brilliant scholastic career, and when he qualified in 1911 was undoubtedly regarded by many of his seniors as the best veterinary graduate of his generation.

After study at the Pasteur Institute, Paris, under a three-years research scholarship, study in Germany having been prevented by the First World War, he served for two years in France with the Army Veterinary Corps, and was mentioned in dispatches. Some years of research under the late Sir John M'Fadyean followed, and he was then appointed to the new chair of veterinary hygiene at the Royal Veterinary College, London, in 1920. He received the degree of D.Sc.(London) in 1926, the title of his thesis being "The Chemotherapy of Surra in Horses and Cattle in India".

In 1921, Edwards was appointed director of the Imperial Bacteriological Laboratory (later Imperial Institute of Veterinary Research), Muktesar, India, the most important veterinary appointment in that country, and for the next eight years produced work of remarkable value, carrying out intensive investigations on a wide range of animal disease subjects.

His research work on rinderpest proved to be of a very high order, although its full value was not universally recognized until after an interval of nearly twenty years. The results of this investigation were not published in detail at the time because of preoccupation with current work.

Rinderpest immunization had tended to be hazardous, partly because of the danger of intercurrent infection with piroplasmosis and certain other diseases precipitated by the body reaction to the vaccine, and partly because of varying susceptibility of cattle to the virus. Edwards conceived the idea of adapting the virus to rabbits as unnatural hosts on the basis of the work of Jenner and of Pasteur, in the hope of obtaining a living virus which would immunize without producing the disease, and he laboriously set out on what appeared to be a hopeless task. He achieved success, but not final success. At the peak of the work his rabbit stock was wiped out by bacterial infection. In India there was no stock of rabbits to replace them and he turned his attention to the goat, again in the hope of producing a suitably modified virus. He succeeded, and his goat-adapted strain of the rinderpest virus has proved to be a highly efficient live vaccine for the immunization of Indian cattle, and it has been used systematically in India ever since with great success. After suitable modification for cattle in Africa, it has proved of great value also in that continent.

Japanese workers produced a rabbit-adapted rinderpest virus in the nineteen-thirties and acknowledged the inspiration of Edwards's work. Their rabbit strain has since proved to be immensely valuable. So Edwards's work on the rabbit-adapted and the goat-adapted strains of the rinderpest virus has stood the test of time and provided outstanding developments in all work on this terrible disease of cattle. Now, for the first time, and entirely as a result of these developments, leaders at international conferences are speaking hopefully of the eradication of rinderpest from continents.

There has been a further development of this work. In the United States in recent years the swine-fever virus has similarly been adapted to rabbits, and the modified strain has been used with great success for the immunization of pigs. American workers have acknowledged the lead provided in this work by the results Edwards achieved with the rinderpest virus. At the present time this new swine-fever vaccine is regarded as the most important advance made in the study of that disease, and great advantages are anticipated from its use.

In 1929 Edwards returned to England and joined the staff of the Foot and Mouth Disease Research Committee, working first at the Lister Institute and later at the Pirbright laboratory.

Edwards published many papers on a variety of subjects, and a number of his contributions will maintain their importance for years to come. He was active over a wide range of veterinary activities in Britain during the past two decades and was very highly respected in his profession.

He was awarded honours by his profession, and when on deputation to the Egyptian Government was awarded the Order of the Nile (3rd Class) by the late King of Egypt. He was a past president of the Section of Comparative Medicine of the Royal Society of Medicine. He was a member of the Councils of both the Royal College of Veterinary Surgeons and of the British Veterinary Association.

During 1916–21 he edited the *Tropical Veterinary Bulletin*, and, after the death of Sir John M'Fadyean, he became one of the editorial board formed to continue the *Journal of Comparative Pathology and Therapeutics*.

Edwards was deeply interested in psychology and in animal behaviour. In recent years he devoted much of his literary activities to veterinary history, on which he published important contributions in the *Veterinary Record* and elsewhere.

W. A. Pool

## Prof. Johan Böhm

The newly organized Czechoslovak Academy of Science and the Research Institute of Organic Syntheses have suffered a great loss by the decease of the distinguished physical chemist, Prof. J. Böhm, on November 27, 1952. Born in 1895 in Budějovice, Southern Bohemia, Böhm studied at the German Institute of Technology and at the University of Prague, and also worked in the Kaiser Wilhelm Institut für physikalische Chemie, Berlin. At that time this Institution was at its height under the leadership of Prof. F. Haber, with collaborators such as v. Hevesy, Willstätter, Zsigmondi, Freundlich and Polányi. Böhm graduated at the period of the successful start of X-ray applications to structural analysis of crystals, and himself added much to the perfection of this method. His first work elucidated the binding of water in zeoliths, and later research solved the structures of several metallic hydroxides, especially of γ-AlO.OH, which modification has been called 'böhmite' in his honour. This was in 1926, in which Böhm also investigated the strongly exothermic spontaneous recrystallization of finely powdered silver and antimony. At the same time, Böhm constructed with Weissenberger the well-known X-ray goniometer.

Soon after that, Böhm went with v. Hevesy to Niels Bohr's laboratory; but when v. Hevesy was invited by the University of Freiburg-im-Breisgau to fit up the Institute of Physical Chemistry he took Böhm with him. Böhm remained in Freiburg until 1934, first building and installing X-ray laboratories, introducing there his new 'secondary' method of structural X-ray analysis, and, as research director in physical chemistry, practical classes in photochemistry and colloids. He became assistant professor in 1934.

However, the Nazi era altered Böhm's scientific life. Profs. v. Hevesy and Böhm had to leave Germany. The latter, who always kept his Czechoslovak nationality, accepted the invitation of the Czechoslovak government to the chair of physical chemistry at the German University in Prague. During the German occupation of Prague, Böhm was again subjected to political pressure; but he never joined the Nazi party, and continued to help his numerous Czech friends in their scientific work in a fearless manner.

Böhm's own research work in the war years concerned again X-ray investigations and photography; but it remains mostly unpublished, as his pupils left Prague in the critical year 1945. When conditions settled down again, Böhm was employed as a research chemist in the national enterprise Rybitví near Prague, and remained there in spite of several offers of a post as a university teacher. The many sufferings he had sustained had deprived him of self-confidence. At last he consented to work in the physico-chemical laboratory of the Czechoslovak Academy of Science and was one of the first of the nominated corresponding members of that institution.

Prof. Böhm possessed not only a great capacity for experimental work, but also a unique strength of character. His philosophical attitude and faith in social justice guided him safely through national and political struggles. His great modesty, self-denial and willingness to help others led to over-work, which destroyed the hopes of his friends just when he had returned to academic research.

J. Heyrovský

## Prof. Otto Pratje

Prof. Otto Pratje, who was both head of the marine geological section of the German Hydrographic Institute and lecturer in geology at the University of Hamburg, died on December 11, at the age of sixty-two.

Although originally committed to a commercial career, Pratje studied geology concurrently for several years in Britain and Sweden. After the First World War, he decided that his profession was not to his taste, and took his doctor's degree at Freiburg in 1921 under Deecke. During the ensuing period he worked as an assistant at the University of Freiburg on the marine sediments of the Continent of Europe.

The course of his life's work was, however, decided by his move to Königsberg, where he acted as a university assistant and lecturer during 1923–27. His chief study was the geology of the sea-bed, and it was to this that he owed his participation in the *Meteor* Atlantic expedition during 1925–26. In 1937 he was appointed to establish and direct the marine geological section of the Deutsche Seewarte at Hamburg. After the Second World War he joined its successor, the German Hydrographic Institute, and also became a member of the lecturing staff of the University of Hamburg.

The abundance of Prof. Pratje's publications bears witness to his diligence and fertile mind, and will be a lasting monument to him. While his earlier papers were devoted to the geological and palæontological problems of the Continent, in particular those of the Jurassic formations of south-west Germany, marine geology came more and more into the foreground during the Königsberg period. At first he wrote several papers on Heligoland, including the well-known geological guide, but then turned completely to the sea-bed. He also made a systematic collection of bottom samples during many research voyages. In addition to a number of papers on the formation of sediments in the North Sea and the Baltic, we owe to him what are believed to be the most detailed geological charts of these seas yet compiled. Parallel with this work, Pratje carried out the laborious evaluation of the bottom samples collected during the *Meteor* expedition, of which two parts have appeared in print. Unfortunately, his official duties, combined with war-time and post-war conditions, prevented the completion of this work. Finally, in an extensive paper in the "Handbuch der Naturwissenschaften", he described the techniques and methods of collecting and evaluating samples from the ocean bottom, supplementing it, in the "Jahrbuch der Geographischen Gesellschaft", with references to his most recent experience.

Prof. Pratje laboured much and achieved much, though some of his work was incomplete when he died. What remains is the memory of a kindly man who was always ready to collaborate, in whose presence no harsh word was ever heard, and who knew how to suffer hard blows with a quiet mind.

## Prof. Francesco Vercelli

We regret to report that the distinguished Italian geophysicist, Prof. F. Vercelli, director of the Geophysical Observatory and of the Thalassographical Institute of Trieste, died, at the age of sixty-nine, on November 24.

Prof. Vercelli contributed to research in several branches of geophysics. In oceanography he investigated the transmission of solar radiation through sea and lake water and the effects of wind and pressure variations on the tides, and led oceanographic expeditions in Italian naval vessels to various parts of the Mediterranean and Red Sea. He devised a method of harmonic analysis and applied it to the prediction of pressure changes. He sought for the sunspot cycle in tree-ring records. His earliest geophysical work was concerned with temperature in tunnels in connexion with the construction of the Simplon tunnel; later, he founded a seismological station at Trieste and took part in seismic and electromagnetic prospecting for oil in the Po valley.

He was appointed director of the Geophysical Institute of Trieste in 1920. When the Institute was divided in 1949, he became director of both the Geophysical Observatory and the Thalassographical Institute. His last years were devoted to preparing a second edition of his book on meteorology, "L'Aria", and to writing a large work on oceanography, "Il Mare".

We regret to announce the following deaths:

Prof. G. D. Hale Carpenter, M.B.E., Hope professor of zoology in the University of Oxford during 1933–48, on January 30, aged seventy.

Prof. J. H. Orton, F.R.S., emeritus professor of zoology, University of Liverpool, and formerly director of the Marine Biological Station, Port Erin, on February 2, aged sixty-eight.

# NEWS and VIEWS

## Prof. P. M. S. Blackett, F.R.S.

On his appointment to the chair of physics at the Imperial College of Science and Technology, London, in succession to Sir George Thomson, Prof. P. M. S. Blackett resigns at the end of the present session from the Langworthy chair of physics in the University of Manchester which he has held since 1937. In the two years before the War, Prof. Blackett created a large and important school of cosmic-ray research in Manchester. Largely through his inspiration at this time, a chair of theoretical physics came into existence—occupied first by Prof. D. R. Hartree and later by Prof. L. Rosenfeld. But perhaps Blackett's most significant achievements belong to the post-war period. As a member of the Barlow Committee he was prominent in securing the expansion of the universities of Great Britain, and with his own department he set a brilliant example in the use of the new opportunities thus provided. An honours school numbering little more than a dozen was immediately increased six-fold, and this expansion in teaching was accompanied by spectacular developments in research, in which Blackett's wide interests and sound judgment were everywhere apparent. After the discovery of the *V*-particles by Rochester and Butler in 1947, the work was extended to the Jungfraujoch and Pic du Midi; while in Manchester, J. G. Wilson's magnetic cosmic-ray spectrograph was constructed and considerable developments took place in all aspects of cosmic-ray research. At the same time the Jodrell Bank Experimental Station was being developed for work in radio astronomy, and Blackett was working on his theory of the magnetic field. Experimental work on the latter provided Blackett with a new outlet for his individual experimental skill, in which he developed magnetometers of very great sensitivity. The width of his interests and activities was again emphasized in 1951 when chairs of theoretical astronomy and of radio astronomy were established in his department.

Blackett exercised a great influence on the post-war developments in the University of Manchester and in administrative affairs. He was dean of the Faculty of Science during 1948–50; a member of Council during 1949–52 and pro-vice-chancellor during 1950–52. He is a member of the National Research Development Corporation and has served on many atomic energy and defence committees. The award of the Nobel Prize in 1948 gave great pleasure to Blackett's many friends throughout the world, who will join in wishing him continued success in his new post. Manchester regrets the loss of one of the world's most distinguished scientists, who enhanced in a brilliant manner a remarkable heritage of Langworthy professors.

## Prof. Willis Jackson

Prof. Willis Jackson has been appointed director of research and development at Metropolitan-Vickers Electrical Co., Ltd., as from July 1 next, in succession to Dr. C. Dannatt, who took over from Sir Arthur Fleming in 1951 (see *Nature*, 168, 587; 1951). Prof. Willis Jackson is professor of electrical engineering in the University of London at the Imperial College of Science and Technology, having succeeded the late Prof. Cecil L. Fortescue in 1946. His career has been closely associated with Manchester, for after graduating from that University he became a college apprentice in the firm to which he is now returning, and later joined the research staff of the organization. He relinquished this position in 1938 on his appointment to the chair of electro-technics at Manchester.

Prof. Jackson's work at the Imperial College has been characterized by the energy and enthusiasm which those who know him expect as a matter of course, and both as head of the Department of Electrical Engineering and, during the past two years, as dean of the City and Guilds College, he has won the respect and affection of his colleagues for the efficient and cheerful way in which he has carried out his many duties. His energies have, however, not been confined to academic matters; among many extra-mural interests he has served on the Council of the Institution of Electrical Engineers and its Education Committee for nine or ten years, has been a member of the Technology Sub-Committee of the University Grants Committee and a member of the Scientific Advisory Council of the Ministry of Supply since 1948, and has taken an active part in the work of many other important bodies concerned with professional education and research. In spite of these varied demands he has found time for personal research, his main interests being in the properties of electrical insulating materials and in micro-wave measurements. Prof. Jackson's wide experience in both education and research augurs well for his success in the responsible position which he is to assume, and the high standards set by his predecessor, Sir Arthur Fleming, whose work at 'Metro-Vick' has won the admiration and respect of the whole engineering profession, will be in safe keeping.

## Higher Technological Education in Britain

In a written answer in the House of Commons on January 29, to questions as to whether the Chancellor of the Exchequer could now give details of plans for the establishment of a technological university or university college of technology in Britain, Mr. J. A. Boyd-Carpenter, Financial Secretary to the Treasury, stated that after consulting the University Grants Committee, the Government proposes to place further resources at the disposal of the University of London to facilitate the expansion of the Imperial College of Science and Technology. The aim would be to raise the number of full-time students from the present 1,650 to 3,000 during the academic quinquennium 1957–62. So that the work of the Imperial College could be co-ordinated with that of other schools of the University, and full advantage taken of the whole of the University's resources, as well as to minimize disturbance of current work of the College, the expansion would take place around the existing site of the College in South Kensington. The College had been invited to submit plans based on the assumption that the College would have first claim on other parts of the area between Prince Consort Road and Imperial Institute Road as it became possible to release them from their present uses. The phasing of the plans would, of course, require careful consideration in consultation with other interests affected.

This development is clearly in pursuance of the policy already announced by the Government of building up at least one institution of university rank devoted predominantly to the teaching and study of higher technology. In addition, the Government proposes to make resources available for further developments in other parts of Great Britain, and the University Grants Committee has been asked to advise the Chancellor of the Exchequer where such further resources might be deployed. These projects are to be additional to the developments of higher technological education already in progress.

### International Council of Scientific Unions: Report for 1951

THE report of the executive committee of the International Council of Scientific Unions for 1951, edited by Prof. F. J. M. Stratton (pp. 108; from the Secretariat, Gonville and Caius College, Cambridge; 1952), includes the text of the revised agreement between the Council and the United Nations Educational, Scientific and Cultural Organization (Unesco) which brings the agreement into line with those made between Unesco and other organizations. The Council has also been granted consultative status by the Economic and Social Council of the United Nations. Rules for Joint Commissions of the Council have been approved by the executive board and are also appended, and under the new rules the future status of five Joint Commissions, which have been in existence for more than three years, was discussed. The Joint Commission for Rheology was renewed for one year on the understanding that it would become a section of the International Union for Theoretical and Applied Mechanics, and the Joint Commissions for the Ionosphere, for Solar and Terrestrial Relationships, for Radiometeorology and for Oceanography were renewed for three years, but the terms of reference of the last-named were restricted to "the investigation of the deep-sea floor". The title of the Joint Commission for Radioactive Standards, Units and Constants has been changed to Joint Commission on Radioactivity. A proposal to form a new Joint Commission on Electronomic Microscopy was approved. The Joint Committee on Physics Abstracting was dissolved at its own request, and the formation of an International Service of Science Abstracting was approved; the new International Abstracting Board--the agreed title for the service—will not accept fresh subjects, however, until the experimental stage with the Committee on Physics Abstracting is complete and the Board well established in that field. Decisions on the admission of the International Unions of Biochemistry and of Scientific Psychology were deferred. In spite of the steady position of the financial balance in the accounts, printing costs give rise to anxiety. Appended to the report of the Executive Committee are the customary reports from the International Unions and the various Joint Commissions. These include a first report from the Joint Commission on High Altitude Research Stations, which held its first meeting at Bagnères-de-Bigorre during August 23–26, 1950, a meeting which appears to have considerably stimulated, *inter alia*, high-altitude research in South America as an international activity.

### Short Circuits set up by Kestrels

MR. H. LLOYD, of the Yorkshire Electricity Board, writes: "66,000 volts transmission lines in the Yorkshire and North Lincolnshire areas had been subject to a number of mysterious faults, which nearly always occurred about dawn, for several years before the trouble was found to be caused by kestrels which were escaping alive. The points of interest in pursuing the investigation into this were, first, how it was that the birds were surviving 38,000 volts applied across their bodies, and second, what was attracting them to the lines? The incidents always occurred in the early morning or in the misty weather when the birds' plumage could be assumed to be damp. The flashover is initiated across the damp wings when the bird is banking steeply with its back to the insulators, and current does not pass through the bird's body. The speed at which the bird is travelling takes it out of the path of the arc before it becomes too severely burnt. Other birds subject to high voltages are normally completely carbonized. It was at first thought that a few enterprising birds had discovered that it was possible to survey the surrounding ground less obtrusively and with less effort when static from a 45-ft. high perch. Gamekeepers and others thought this improbable, and the theory did not agree with the damage to the birds. There was no evidence that small birds were using the somewhat exposed cross-arms as perches, and we were informed again that kestrels generally preferred ground game. One day, a substation attendant, during misty weather, noticed a kestrel circling a string of insulators in ever-narrowing circles and, had the bird not been scared off, it would probably have run into trouble. The insulators, as is usual under humid conditions, were discharging and emitting an intermittent buzzing noise, and this seems to provide the attraction. In a very recent case the weather was foggy and visibility limited to a few yards. This seems to imply that kestrels hunt by ear as well as sight, and it occurred to me that this might be of interest to ornithologists and others. Bird lovers will be glad to know that, with later forms of construction, two kestrels will have to execute a very complex movement before they get into trouble".

This interesting observation is most likely explained by the possibility of kestrels hunting by ear as well as by sight. Miss Frances Pitt writes: "The kestrel certainly has good hearing. A tame one I had came from a considerable distance when called in a quite low voice. But the bird's method of hunting suggests that it depends on its eyes to find prey".

### Science and Film

A RECENT issue of *Science and Film* is largely taken up with the activities which went on at the International Scientific Film Association's sixth yearly congress in Paris during September 1952 (1, No. 4; December 1952). Among the films which were presented at the congress was one, "Introducing the New Worker", which deals with the problem of works relations and factory psychology. A remarkable film was one from Eastern Germany called "Arbeit aus neuem Geist", dealing with methods of raising production-levels by means of the analysis of work done and by creating a profitable emulation or 'activism' in each team of workers. The high-speed camera was used in France for making a valuable research film on argon arc-welding, while another research film from France was the "Study of Flames", made for the Institut de la Recherche dans la Sidérurgie. Among industrial training and instructional films presented at the congress were the British films, "Basic Principles of Lubrication", "Submarine Control" and "Hardening and Tempering Carbon Steel". From Czechoslovakia came the "Polarograph" and "Electro-erosive Machining", while France supplied "Les Miroirs Plans", a teaching film on plane mirrors. Among the more outstanding documentary films were "Le Cuivre", describing the process of copper-mining in the Belgian Congo; "Charge de Rupture", describing the work of the

Laboratory for Research into Reinforced Concrete Techniques at the University of Ghent; and "Volga-Don Canal", the preliminary to a major Soviet film in colour on the same subject which is shortly to be made available for public distribution. The journal also describes various technical demonstrations at the congress, the use of sound film loops in industrial training, stereoscopic cinematography and a new device for automatic photometry.

### Experimental Elimination of Chromatophores and Eyespot in *Euglena*

E. G. and O. Pringsheim (*New Phytol.*, 51, No. 1, 65; 1952) have reported a very interesting case of the permanent elimination of plastids and eyespot in *Euglena gracilis* by exposure to high temperature and also by treatment with streptomycin. When *E. gracilis* was grown for 5–6 days at 34–35° C.—just below the maximum for multiplication—the chromatophores of most strains were caused to disintegrate and permanently apoplastidic strains were obtained. In a few of the strains the eyespot also disappeared permanently. Considerable differences in response to the treatment were observed in different strains, the effect of streptomycin, strain for strain, yielding parallel results. Both the chromatophores and eyespots are independent, self-reproducing cell components, and once destroyed do not reappear. The artificially produced strains apparently retain their heterotrophic nutrition and vigour indefinitely. The differences in the response of different strains of the organism to the experimental treatments are due to inherent, that is, genetical, factors.

### Integration of Scientific Thought

Some years ago, the inherent dangers of specialist knowledge—when carried to extremes—were foreseen, and its impact upon Western culture in general led to the formation of the Institute for the Unity of Science as an outgrowth of the American Academy of Arts and Sciences. Prof. P. Frank, in some interesting remarks to a meeting of the Institute, reported in a recent publication entitled "Contributions to the Analysis and Synthesis of Knowledge" (*Proc. Amer. Acad. Arts Sci.*, 80, Part 1; 1951; pp. 112, 2 dollars), pleads for the reinstatement of philosophy as a link between the arts and sciences, while President J. B. Conant (Harvard University) stresses the dynamic nature of science. A threefold scheme is then developed by some of the leading methodologists and semanticists of the United States, namely: science and man; the 'meaning' of scientific statements; and the role of 'abstract objects' in science. As a collection, the contributions are stimulating, and calculated to advance the integration of a wide field of studies.

### British Astronomical Association: Annual General Meeting

At the annual general meeting of the British Astronomical Association, held in Burlington House, London, on October 29, the retiring president, Dr. G. Merton, delivered an address in which he dealt first of all with the internal affairs of the Association. It is very satisfactory to know that the membership, which was 856 in 1942, is now well over two thousand and is still increasing, and also that the observing sections continue to flourish with increasing membership as well as with increasing activity when observing conditions are favourable. Dr. Merton took as his main subject, "Photography and the Amateur Astronomer", in which he gave a historical sketch of the developments in photography, referring to a number of astronomers who had carried out very useful work in this branch. The address was illustrated by a series of lantern slides, and, in concluding it, he pointed out a number of ways in which amateur astronomers could make use of photography. In particular, Dr. Merton referred to the scheme of the new director of the Aurora and Zodiacal Light Section for obtaining co-operative work in parallactic photography with fast cameras. During the evening the Walter Goodacre Medal and Gift were presented to Mr. Frank Maurice Holborn. Dr. Merton gave a short account of Mr. Holborn's work in astronomy in different branches, but more especially on variable stars, and paid a high tribute to his devotion to the work of the Variable Star Section, as well as to his contributions to other sections. The new president of the Association, Mr. E. H. Collinson, who took over from Dr. Merton, is well known for his contributions to astronomy in various branches, especially for his papers on meteors, and his photography of them, a branch on which he has worked for many years.

### Bibliography of Differential Thermal Analysis

Any material which undergoes a phase change when heated can be studied by the method of differential thermal analysis, and this method is widely used by geologists, investigators in the fields of ceramics and agriculture, and by chemists, metallurgists and fuel technologists. At the Institute of Science and Technology of the University of Arkansas, Fayetteville, Prof. W. J. Smothers, Y. Chiang and A. Wilson have compiled a "Bibliography of Differential Thermal Analysis" (Research Series No. 24; pp. 44; 1951) which lists 165 papers published between 1887 and 1950 inclusive, and facilitates the identification of relatively unknown substances that are often present in materials subjected to thermal analysis. The bibliography consists of four parts. The first presents a brief description and history of the method; then follows the chronologically arranged list of technical papers; the third is an author index, and the last part is an index of materials analysed by the differential thermal method. The physicist will probably find the short section dealing with equipment of most interest. The best type of thermocouple and its position in the sample, the heating-rate, furnaces with uniform heating-rate and the replacement of photographic by electronic recording, are briefly discussed. As an initial, and quick, reference work, this pamphlet should prove useful.

### Royal Sanitary Institute: Annual Health Congress

The annual Health Congress of the Royal Sanitary Institute will be held in Hastings during April 28–May 1, under the presidency of Lord Eustace Percy. The Congress will be divided into eight sections (*A–H*) and four conferences (1–4) as follows: sections (*A*) preventive medicine, (*B*) engineering and architecture, (*C*) maternal and child health, (*D*) veterinary hygiene, (*E*) food and nutrition (in conjunction with the Food Group, Society of Chemical Industry), (*F*) housing and town planning, (*G*) tropical hygiene, and (*H*) occupational health; conferences (1) medical officers of health, (2) engineers and surveyors, (3) sanitary inspectors, and (4) health visitors. It is anticipated that about two thousand five hundred persons will attend the Congress, including representatives of local authorities, government departments, public bodies, universities and learned societies in Great Britain and elsewhere. Further details can be obtained from the Institute at 90 Buckingham Palace Road, London, S.W.1.

### Thirteenth International Congress of Pure and Applied Chemistry

THE Thirteenth International Congress of Pure and Applied Chemistry will be held in Stockholm during July 29–August 4, 1953, and in Uppsala during August 5–7, 1953. At the same time the Seventeenth Conference of the International Union of Pure and Applied Chemistry will take place. The Congress will comprise a Physical Chemistry Section with the following groups: chemical thermodynamics and thermochemistry, electrochemistry, surface chemistry, colloid chemistry, macromolecular chemistry, chemical kinetics, reactions of free radicals, and other fields of physical chemistry. There will also be a symposium on the chemistry of wood and wood constituents, which will be divided into three sections: structural chemistry of wood constituents, chemistry of cellulose and hemicellulose, and the chemistry of lignin. Immediately after the Congress a symposium on macromolecules will be held in Uppsala. Application forms for attendance at the Congress (to be completed by March 1) and further information can be obtained from the general secretary, Dr. Bengt Sandberg, Thirteenth International Congress of Pure and Applied Chemistry, Stockholm 70.

### First World Congress on Fertility and Sterility, New York

THE First World Congress on Fertility and Sterility will be held during May 25–31 at the Henry Hudson Hotel, New York City, under the sponsorship of the International Fertility Association with the co-operation of the American Society for the Study of Sterility. About eighteen hundred scientific workers from fifty-one countries are expected to attend. Twenty-three scientific sessions will be held, which will embrace the entire field of fertility and sterility, including sessions dealing with socio-economic factors, psychosomatic aspects and artificial insemination. The sessions will be conducted in English, French and Spanish, with the use of earphones and simultaneous translations, as in the United Nations meetings. In addition to the scientific sessions there will be medical round-table discussions, question-and-answer periods, scientific exhibits and films. Those who wish to attend should register as soon as possible with the Chairman of the Local Arrangements Committee, 1160 Fifth Avenue, New York 29, N.Y.

### Third International Conference on Soil Mechanics and Foundation Engineering

THE Third International Conference on Soil Mechanics and Foundation Engineering will be held in Switzerland during August 16–27. The first part of the Conference will take place in the Kongresshaus, Zurich, during August 16–21, when the programme will consist of the main bulk of the lectures and discussions with receptions, excursions, visits to laboratories, and a banquet and ball. During August 22–25 there will be a four-day tour through Switzerland, when the opportunity will be given of seeing not only points of interest for geotechnical and foundation engineering but also something of the country's natural beauty. The final session will be held in Lausanne on August 26, after which an excursion will be made to the dams of Grande Dixence and Mauvoisin, which are under construction. The official languages of the Conference will be English and French. Reservations for hotels at Zurich and Lausanne and for the excursions should be made not later than June 15, preferably as soon as possible. All inquiries should be addressed to the general secretary of the Conference, Dr. A. von Moos, Gloriastrasse 39, Zurich 6.

### Developments in Microscopical Methods

THE Royal Microscopical Society (Industrial Section), in co-operation with the Optical Group of the Physical Society, the Physical Methods Group of the Society of Public Analysts and Other Analytical Chemists, and the Industrial Spectroscopy Group of the Institute of Physics, is organising a meeting under the above title, to be held at King's College, London, on March 20. The first session of the meeting, at 2.30 p.m., will be a lecture demonstration, "The Use of the Polarizing Microscope in Organic Chemical Research". The second session, beginning at 4.30 p.m., will consist of a number of short papers, the general theme of which will be "Useful Attachments to the Microscope and Analytical Methods"; a number of exhibits and demonstrations illustrating the same theme will be on view in adjacent laboratories. In the third session, at 6.15 p.m., there will be a lecture demonstration on "Cinemicrography". Full details of the meeting, with synopses of the papers and short descriptions of the exhibits, are given in the programme, which can be obtained (price 1*s*.) from the Assistant Secretary, Royal Microscopical Society, Tavistock House South, Tavistock Square, London, W.C.1.

### Guido Fubini Prize in Mathematics

AN international prize in mathematics, in memory of the late Guido Fubini, has been founded by his friends and admirers and will be administered by the Unione Matematica Italiana. The prize will consist of Italian currency equivalent to about 550 gm. of gold and will be awarded for important contributions in the field of differential geometry published between January 1, 1946, and December 31, 1953. Applicants are invited to submit their work to the Unione Matematica Italiana (address: presso Istituto Matematico 'Pincherle', Università di Bologna) before March 31, 1954; but the awarding committee may also consider publications for which no such application is made. If there should be no suitable work in differential geometry, the committee can award the prize for contributions made in the same period to the theory of automorphic functions and related topics.

### University of Birmingham

THE following appointments have recently been made in the University of Birmingham. To be lecturers: Dr. W. O. Lock (physics), T. Broom (industrial metallurgy), Dr. G. F. Eveson (mining), and Dr. R. C. Porter (chemical engineering). To be Imperial Chemical Industries, Ltd., Research Fellows: Dr. A. J. Nutten (chemistry) and Dr. G. K. Williamson (metallurgy). J. T. Edward, Imperial Chemical Industries, Ltd., Research Fellow in the Department of Chemistry, has resigned. The title of University Research Fellow has been conferred on K. H. Stark during the tenure of his post in the Department of

Electrical Engineering. The degree of D.Sc. of the University has been conferred on F. R. N. Nabarro (metallurgy) and F. J. Richards (botany).

### Nuffield Foundation Awards in Dentistry, Biology and the Social Sciences

THE Nuffield Foundation is offering a number of fellowships, scholarships and bursaries in the fields of dentistry, biology and the social sciences as follows. The fellowships for dentistry are for persons, aged 25–35 years, with dental qualifications, to receive additional training in pure and applied science so as to undertake an academic career in dentistry, and also to enable graduates in medicine or science to receive training (not necessarily for a registrable dental qualification) that will fit them for teaching and research in dental health and disease; the fellowships are worth £500–800 a year for one to three years, and applications must be received by March 1. Dental scholarships, normally for one year only, are available for students at university dental schools in the United Kingdom and cover tuition fees and a subsistence allowance of not more than £200; applications must be received by June 30. The Foundation's scholarships and bursaries in biology and the social sciences are for graduates of British universities, preferably within the age-group of 22–35 years. The awards in biology are for persons who have graduated in physics, chemistry or mathematics but who have had no training in a biological subject, and who wish to receive such training in biology as will enable them to undertake research and teaching in the United Kingdom in the biological sciences; the scholarships are for persons with some previous experience in postgraduate research in their own subject, and the bursaries for those who have recently graduated, and in both cases the Foundation will pay the cost of university and/or college fees in addition to a maintenance award; applications must be received by April 1. The awards for the social sciences are the same as those for biology except that the application forms must be received by May 1 and the holder may have a degree in any subject other than the social sciences, psychology or economics, though one in the natural sciences or mathematics is preferable; subjects suitable for study are political science, social psychology, anthropology, social statistics and sociology generally, but not economics. Application forms for all these awards and further information can be obtained from the Secretary, Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N.W.1.

### Sociological Research in Africa South of the Sahara

A MEETING of specialists engaged in the planning of sociological research will be held during the last week of this month in Kampala, Uganda, by the Scientific Council for Africa South of the Sahara, on the occasion of the second seminar of Belgian and British sociological research workers. The meeting will consider present major problems and projects of sociological research in Africa south of the Sahara, and will make suggestions for special studies and means of co-ordination concerning sociological research. Among those who are expected to attend will be Gouverneur Deschamps from the Ministère de la France d'Outre-Mer, Paris; Prof. Griaule, professor of ethnology in the University of Paris; Dr. L. van den Berghe, director of the Institut pour la Recherche Scientifique en Afrique Centrale, Congo Belge; Dr. A. I. Richards, director of the East African Institute of Social Research, Kampala; Prof. A. Mendes Correa, director of the École Supérieure Coloniale, Lisbon; Mr. V. R. Sutton, of the South African National Institute for Personnel Research; and Dr. Clyde Mitchell, director of the Rhodes-Livingstone Museum, Northern Rhodesia.

### Announcements

DR. E. MARSDEN, representative of New Zealand on the Executive Council of the Commonwealth Agricultural Bureaux, Farnham Royal, Bucks, has been elected chairman of the Council in succession to Mr. J. E. Cummins, representative of the Commonwealth of Australia. Mr. W. F. C. Morton (Union of South Africa) follows Dr. G. R. Bates (Southern Rhodesia) as vice-chairman of the Council.

APPLICATIONS are invited for Lady Tata Memorial Fund grants, scholarships and fellowships to scientific workers of any nationality for research on diseases of the blood, with special reference to leukæmia, in the academic year beginning October 1 next. Grants are made for research expenses, scholarships are awarded as personal remuneration, their normal value being £600 for whole-time research, and fellowships will be for workers with considerable research experience, the stipend being £1,000 a year. Applications must be submitted before March 31, and the awards will be announced in June. Forms of application and further information can be obtained from the Secretary of the Scientific Advisory Committee, c/o Medical Research Council, 38 Old Queen Street, Westminster, London, S.W.1.

No. 6 of the "Bibliography of Scientific Publications of South Asia", covering India, Burma and Ceylon for the period July–December 1951 (pp. 124. Delhi: South Asia Science Co-operation Office, 1952), includes a catalogue of scientific periodicals besides the usual classified list of titles and supplementary list of new periodicals and changes of name, address, frequency, etc. The periodicals are listed alphabetically by title, and details of scientific periodicals which have ceased to appear but which are still of interest to scientific workers are included. Besides particulars of frequency, size and purpose of the periodicals listed, the catalogue gives the publisher's address and the first date of publication.

LIKE many of its contemporaries in the petroleum field, *The Lamp*, which is the house organ of the Standard Oil Co. (New Jersey), combines knowledge with entertainment. Issue No. 3 for 1952 is particularly characterized by reproductions of life in the Canary Islands, painted by John Groth. Other features describe a push-button parking-system for cars, in a tall building twenty-five feet wide in Washington, D.C., where seventy-two cars can be automatically garaged in a space which, on the ground, would only accommodate nine; this innovation could well engage the attention of local authorities in congested cities in Great Britain. There is an article on Bermondsey, one of London's oldest boroughs, some account of the Company's oil explorations in foreign lands, and an interesting section on 'hurricane hunters' by the United States Air Weather Service in the Caribbean region.

ERRATUM. We much regret that in the communication entitled "Height of the Potential Barrier in Barrier Layer Cells" in *Nature* of January 31, p. 219, the graph has been inverted.

# NEW SCIENCE BUILDING AT BEDFORD COLLEGE, UNIVERSITY OF LONDON

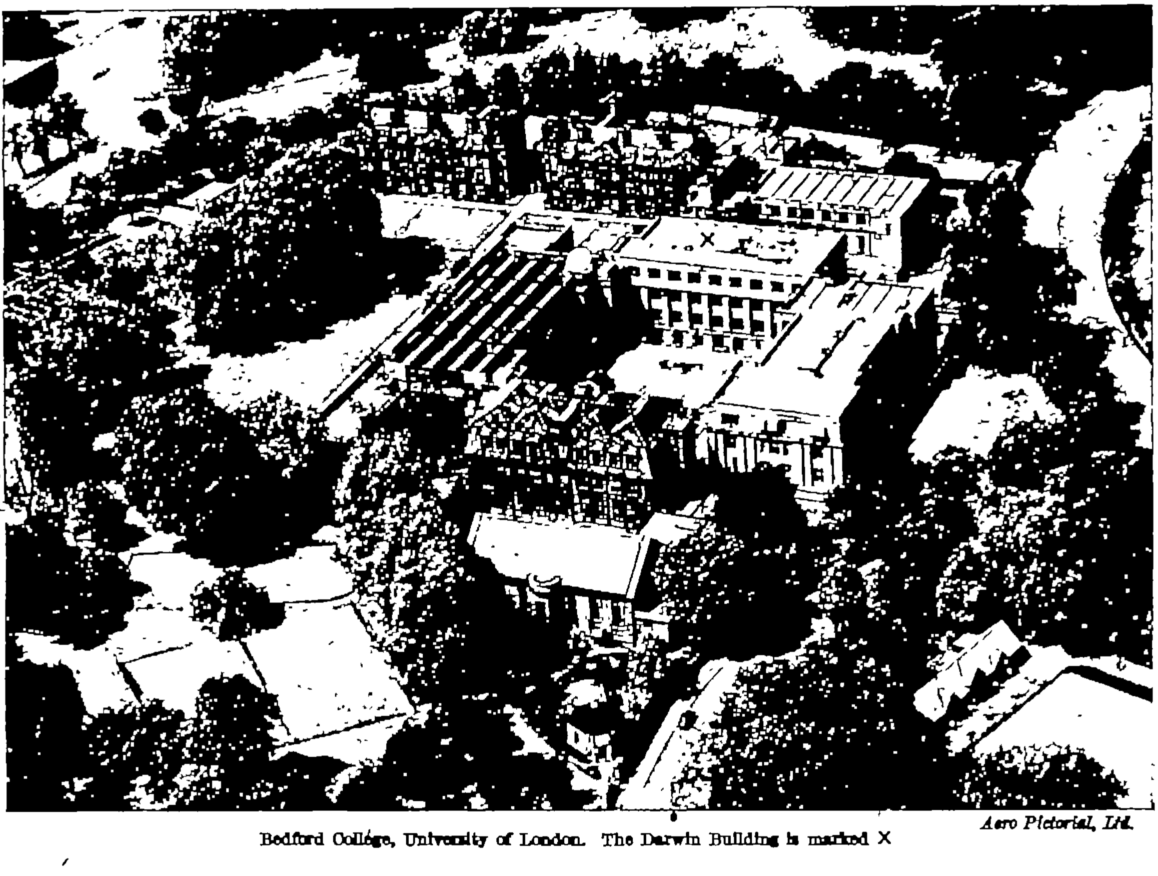
THE Biology and Geology Departments of Bedford College were destroyed by enemy action in 1941. A new building has now been completed on the original site. It was formally opened by the Chancellor of the University of London, the Earl of Athlone, and Princess Alice on October 28 last.

The new structure, of which the architects were Maxwell Ayrton and Partners, has been named the Darwin Building. The name is particularly appropriate for biological and geological laboratories, recalling, as it does, Charles Darwin; but the building is actually dedicated to his son Leonard, who was a member of the College Council during 1898–1925. Another link with the Darwin family is the fact that Erasmus, elder brother of Charles, was an original trustee of the College in 1849 and a member of the Council for nearly twenty years. A grand-daughter of Charles Darwin, Mrs. Ruth Rees Thomas, is to-day a governor of the College.

Zoology is housed on the top story, with botany beneath it and geology on the upper ground floor. Special features of the building are the large windows, valuable for microscopic work, teak benches and floors, heating by ceiling panels, and compressed air and vacuum services. Each department has its own library. A large lecture theatre is common to the three departments, while each of them has its own lecture room. The lower ground floor is shared between the departments and there is a passenger lift.

The Zoology Department (Prof. H. Munro Fox), in the planning of which the senior lecturer, Miss F. E. Ince, gave valuable help, is designed so that a large teaching laboratory occupies two-fifths of the floor space, with windows on three sides. The museum collection is displayed in glass cases around this laboratory. The Department contains individual research rooms for the five members of staff and three research rooms for five postgraduate students, grouped around preparation rooms and stores. The lower ground floor provides a workshop, dark-room, aquarium room, and two constant-temperature rooms. The research work deals at present with respiratory pigments and with the metabolism, osmoregulation, taxonomy and embryology of Crustacea.

The Botany Department (Prof. L. J. Audus), in addition to general and honours teaching laboratories, has a laboratory for instruction in special experimental disciplines (for example, biochemistry, plant physiology, soil chemistry, etc.). The departmental museum collection is housed in glass-fronted cupboards in laboratories and corridors. There are five staff research rooms, a postgraduate research laboratory and a large constant-temperature room provided with high-intensity fluorescent light for growth experiments with plants in artificial day-lengths. Current research is mainly on the physiology of growth, with particular reference to chemical regulators, ecology and wheat genetics. The herbarium has built-in insect-proof cabinets for both teaching and research collections. There are also two dark-rooms, a medium room, a sterile room and a workshop.



Aero Pictorial, Ltd.

Bedford College, University of London. The Darwin Building is marked X

The Geology Department (Prof. L. Hawkes) comprises one large general laboratory and museum, a smaller palæontology laboratory, three research laboratories, a chemical laboratory and a technician's room. Two rooms on the lower ground floor are equipped for rock-cutting and optical work.

---

# CENTRAL PUBLIC HEALTH LABORATORY, COLINDALE

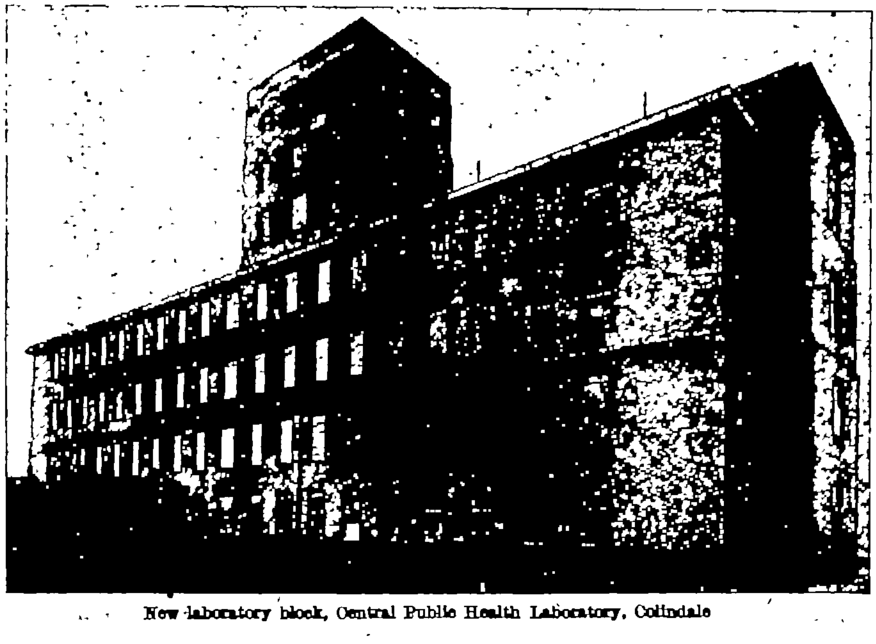
## NEW LABORATORY BLOCK

On January 15 the new laboratory block of the Central Public Health Laboratory at Colindale was formally opened by the Minister of Health. The Minister, accompanied by his Parliamentary Secretary, Miss Hornsby-Smith, Sir John Hawton and Sir John Charles, were met by the chairman of the Medical Research Council (Lord Limerick), the first secretary (Sir Harold Himsworth), the second secretary (Sir Arthur Landsborough Thomson), the director of the Public Health Laboratory Service (Dr. G. S. Wilson), and were conducted over the main buildings by the director of the Colindale Laboratories (Lieut.-Colonel H. J. Bensted).

There were no formal demonstrations set out and the Minister met the heads of the various departments and their staff carrying out their normal duties; of topical interest were the roll-tube tissue culture technique for the cultivation of the poliomyelitis viruses, and the chick embryo cultivation of the influenza virus.

In the library of the new building, the Minister was introduced by Lord Limerick, and in a short address he described the development of the Public Health Laboratory Service and how it came about that the Medical Research Council is directing, and will continue to direct for an indefinite period, this Service for the Ministry of Health. In declaring open the new building he paid tribute to the architect, Mr. Maxwell Ayrton, and the builders, Messrs. Trollope and Colls, Ltd.

The new building consists of a four-floor block of a pleasing brick construction, approximately 180 ft. long and 45 ft. wide, with a central tower extending upwards for a further four floors. The top of the tower houses reinforced concrete water-tanks to supply the needs of all the laboratory buildings. The rooms under this are designed for office and record purposes. A door from the vestibule on the fourth floor leads to the roof space, which runs the full length of the building and in which is housed ventilating plant, air filters, etc., and some of the compressors for the refrigeration units on the laboratory floor below. There is also ample storage accommodation in this space.



New laboratory block, Central Public Health Laboratory, Colindale

A basement under the central part of the building houses more plant and also a gas-fired incinerator, the flue of which passes up to the top of the tower more than 90 ft. above.

The front of the building faces west, and all the windows on that side are protected from the setting sun by green sun-blinds operated from the inside. At the south end there is a service lift for animals and equipment travelling directly to the third floor (Virus Department) without intermediate stops, and at the north end a similar type of lift serves all the other floors. In the centre a passenger lift goes up to the top of the tower. There is a central staircase, broken at the third floor, for normal foot traffic, while there are emergency downstair cases at either end of the corridors.

In designing this laboratory block, one of the principles kept in mind was, so far as possible, to standardize the layout for each floor but at the same time to make provision (should future requirements necessitate it) for alteration in the size of some of the rooms without interfering with the main construction. On each floor, the first rooms at the south end of the building form a suite comprising preparation room, sterilizing and wash-up kitchen, sterile glass-ware store and sterile room, where a positive pressure of filtered air can be maintained. Each floor also has shower-baths and changing rooms. There are also incubator rooms (37·5° C.) and cold rooms (+ 4° C.). Secretarial assistance in adjacent offices is provided for each group of laboratories.

Central corridors run the full length of the building with laboratory rooms approximately 14 ft. deep on either side. Single-unit rooms are just under 8 ft. wide, and two-, three- and four-unit rooms are multiples of this figure in width. The most common size is the standard two-unit room with a working bench across the windows at 2 ft. 9 in. high, containing one small staining sink in the centre and a drip sink for filter pump, etc., at one end. There are a side bench for water-baths, etc., and a washing-up sink with draining board on the opposite side. A convenient double bench is placed centrally, half of which is 3 ft. high, and the other half, serving as a writing desk, is 2 ft. 6 in. All benching is of teak, and the under-bench furniture is of West African mahogany. The front and side under-bench furniture consists of movable nests of drawers, paired cupboards with adjustable shelves, and open microscope cabinet containers. The central benches are supported by suitable linking of similar cupboard or drawer units.

Simple services are carried on the walls under the benches and consist of electric points, gas, and hot and cold water only. Other gas and electric points are 9 in. above floor-level for small refrigerators, centrifuges and incubators. Ample ceiling lights are provided by opal tungsten lights, while fitted 'Anglepoise' lamps cover each front bench for close work. 'Opalite' shelving for reagents is fitted over staining sinks and at the sides. A capacious double cupboard with adjustable shelving is suitably placed in one corner.

The above description is typical of the standard two-unit room, and although somewhat different arrangements appear in the rooms of other sizes, the same general principles are observed.

The top laboratory floor is devoted to the study of virus diseases, and it is here that refrigeration units are of greatest importance. There is a large + 4° C. room, a − 30° C. room, and inside the latter are chambers maintained at − 70° C. The compressors for these are housed in the roof space. In the centrifuge room on this floor there are also two small independent − 70° C. refrigerator cabinets and a high-speed refrigerated centrifuge. Two animal inoculation rooms with special inoculation boxes connected to exhaust ducts are not quite complete; these ducts are being provided with high-temperature heaters to burn away virus-laden air before it passes out to the open.

The second floor houses the Air Hygiene Laboratories and, under the same director, the Streptococcal and Staphylococcal Reference Laboratories. The novel feature here is an experimental room for research into the bacterial contamination of air. On the same floor is an assembly room for special apparatus required in this section, much of which is machined in an associated outbuilding workshop.

On the first floor are the Food Hygiene Laboratory, Salmonella and the Dysentery Reference Laboratories. These are situated in one-, two- and three-unit rooms of standard design.

The Epidemiological Research Laboratory occupies one-half of the ground floor, the remainder of which consists of small and medium-sized research laboratories for individual workers.

The Routine Department, the Central Enteric Reference Laboratory and Bureau, the Standards Laboratory for Serological Reagents and the Media Kitchens, etc., remain in the old building, but with improved accommodation, while the National Collection of Type Cultures continues to occupy the same rooms as previously.

Owing to economy cuts, it has not been possible to carry out all the improvements originally planned; but it has been possible to convert the old stable, used for inoculating calves when the building belonged to the Government Lymph Establishment, into an excellent research library. It can serve also as a lecture hall for an audience of about a hundred persons, and it was in this very recently completed room that the Minister of Health addressed the invited gathering after his inspection of the new building.

# THE 'COMET' AIR-LINER

In a Friday Evening Discourse delivered at the Royal Institution, London, on November 21, Mr. C. T. Wilkins, assistant chief designer of the De Havilland Aircraft Co., Ltd., discussed the new 'Comet' air-liner.

The end of the Second World War left United States aircraft manufacturers with undisputed supremacy in the field of transport aeroplanes. Some six to eight years are needed to bring a modern air-liner into service from the initial design stage, and Mr. Wilkins pointed out that any attempt of the De Havilland Co. to base its designs on United States practice would not have been likely to produce an aeroplane with the necessary competitive margin. Instead, it was decided to draw on the mounting British experience with the jet engine, the main potential gains being speed, absence of vibration and relative simplicity.

The most promising configuration of aeroplane for this engine appeared to be the tail-less with swept-back wings, and a De Havilland 'Vampire' was modified into the 'D.H. 108'. This became the first British aeroplane to fly faster than sound in a dive, while level speeds at a little more than 600 m.p.h. were possible. This layout, when translated into air-liner practice, promised to be only 50 m.p.h. faster than the rather more orthodox configuration now seen in the 'Comet', and this latter was chosen mainly in order to provide a design for which production orders could be prudently made from the 'drawing board'. The British Overseas Airways Corporation, the former British South American Airways Corporation and the Ministry of Supply were courageous enough to give orders for a total of sixteen 'Comets' at that stage. This has meant a saving of two years in getting the aircraft into service due to the elimination of the 'prototype' stage. It took two and three-quarter years from the time that the conception was settled to the first flight, and an equal period until the 'Comet' came into service. The following are some of the problems which had to be solved.

*Choice of engine.* The 'Comet I' is fitted with the 'Ghost' centrifugal engine. This choice was dictated by expediency, and the later 'Comet' series will have the more powerful and efficient 'axial' engines which are now available.

*Flying at high altitude.* The optimum altitude for a flight of given stage-length is a function of the aircraft weight, and it therefore changes during flight as the fuel is consumed. A typical cruising procedure worked out for the 'Comet' requires an initial climb to 33,000 ft. in thirty minutes, followed by a gradual ascent to 40,000 ft. At this height the atmospheric pressure is 2 lb./sq. in., a temperature of − 73° C. has been recorded and the air is practically dry. These figures indicate the need for reliably engineered cabin pressurization, heating and humidification. At the time of design, little was known of conditions in the upper atmosphere, and a De Havilland 'Vampire' was adapted for making the necessary high-altitude research. This aeroplane established the present world altitude record of 59,446 ft.

*Drag.* The critical Mach number of flight above which the 'compressibility' drag rise becomes severe has been kept relatively high by the use of a thin swept-back wing and by careful design of the rest of the aeroplane. This is particularly necessary, since the speed of sound at the cruising altitude is only nine-tenths of its sea-level value.

*Tare weight.* The pay load of the 'Comet' is one-tenth of its 'all-up weight', while the fuel accounts for 49 per cent of the weight at take-off, and any unexpected changes in the weight of structure or fuel therefore have rather larger effects on the magnitude of the payload. However, the absence of airscrews ameliorates the problem not only due to the direct saving in weight but also due to the considerable reduction in the size of the undercarriage.

*Fuel storage.* Seven thousand imperial gallons of fuel are fitted into a thin wing of 115 ft. span, since it is inadmissible to use the fuselage for storage. To save space, tanks integral with the wing structure are used. The problems to be overcome here arise from the structural deformation in flight and from the high permeability of kerosine. The use of metal-to-metal bonding is superior to the classical riveted joints in this connexion, and it is used extensively throughout the 'Comet'. The fuel should be carried far out along the wing in order to reduce the bending moment at the wing root. In a swept wing this presents problems of the shift of centre of gravity, and the order of fuel usage becomes important. Kerosine is a safer fuel than petrol, but fire precautions are taken very seriously since the relighting of 'out' engines is to take place in the air.

*Controls.* The achievement of light control-surface operation is possible by aerodynamic means or by the use of power operation. The former alternative was decided against, in view of the long time usually taken in the early flight-trials to get the controls 'right'. No other useful flight-tests are possible until this stage is reached. A power-operated system, however, may be given thousands of hours of use in a ground rig in which most of the conditions of flight are simulated. For safety, each control is provided with two entirely independent power-units.

The solution of these and many other problems is the business of a design team consisting of designers, aerodynamicists and stress-men. Further necessary departments are structural testing, experimental, production and service. The organization is now developing the 'Comet II', which is the original machine modified to take the more powerful Rolls Royce 'Avon' engine, and the 'Comet III', a larger aeroplane altogether.

## BRITISH GELATINE AND GLUE RESEARCH ASSOCIATION

THE sixth meeting of the Research Panel of the British Gelatine and Glue Research Association was held at Beale's Restaurant, London, N.7, on November 27, 1952, with Mr. S. G. Hudson (Richard Hodgson and Sons, Ltd.), chairman of the Association, in the chair. Seventy-two persons attended the meeting, including representatives of the manufacturers of plant for the industry.

The meeting was the first held by the Association at which the papers were concerned with practical questions closely related to manufacture. This provided increased opportunity for discussion, of which full advantage was taken. The first paper, "Tannery Treatment of Pieces and Fleshings", by Dr. W. E. Braybrooks (Stokes and Co., Ltd.), described the processes to which the raw materials of the hide gelatine and glue industry are subjected in the tannery prior to dispatch to the gelatine works. The effect was discussed of short dehairing processes, using rotating drums in place of lime pits, on the hide itself, and often using substantial quantities of sodium sulphide in addition to lime.

In the second paper, "The Extraction of Hides", Mr. D. Fysh, of the Association's staff, described a series of experiments in which the industrial treatment of hides by lime suspensions, followed by neutralization, and then extraction of gelatine, was repeated on the laboratory scale. This enabled a number of variables to be studied, such as pH of extraction, time and temperature of extraction, period of lime treatment, etc. The gelatine produced was evaluated by means of measurements of its physical properties. The third paper was by Mr. D. B. Hall (John Knight, Ltd.), entitled "Bones Processing", in which he presented a detailed account of the origin, handling and processing of the raw material of the bone glue factory. The stage-by-stage analysis of the process showed the problems which arise in the various plant operations. Dr. E. M. Vyner (Sheppy Glue and Chemical Works, Ltd.) gave the final paper, under the title "Aspects of the Evaporation and Drying Process in the Glue and Gelatine Industry". Dr. Vyner reviewed the many possible methods by which a dry end-product may be obtained from a gelatine or glue solution. Apart from the normal methods of multi-effect evaporation, setting and drying, spray-drying and freeze-drying have been tried.

On the previous day, at the annual general meeting, Mr. G. W. Odey, chairman of Barrow, Hepburn and Gale, Ltd., was re-elected president of the Association. The chairman of the Association, Mr. S. G. Hudson, stressed the importance to firms using gelatine and glue of the work on this aspect being commenced by the Association. The director of research, Mr. A. G. Ward, in his report, and Sir Roger Duncalfe, chairman of British Glues and Chemicals, Ltd., who proposed a vote of thanks to the council and staff, both emphasized the value of close contact between the Association and the industry.

## CAREERS IN BIOLOGY

THE Institute of Biology recently held a second symposium on "Biology as a Career", at which were discussed fields not covered by the Edinburgh conference (*Nature*, 169, 1034; 1952). A theme common to many of the papers was the need for more biologists having a better training in chemistry and physics.

Sir Harold Himsworth (secretary, Medical Research Council) said that in modern medical research the collaboration of workers from many scientific disciplines is needed. On the scientific staff of the Medical Research Council there are some 440 graduates of whom one-third are medically qualified. Apart from the National Institute for Medical Research, the majority of the Council's staff work in special units which are similar in constitution and size to university professorial units and most of which are associated with universities. In addition, the Council has a system of scholarships for training in research methods. These are designed to enable first-degree graduates to supplement their training and experience in order to equip them for biological research in many fields for which competence in several branches of natural science is necessary. It is perhaps significant that, of those who have received grants, more than half needed training in chemistry and a quarter in anatomy, physiology, pharmacology, embryology or histology.

The work of the Agricultural Research Council in promoting investigations on fundamental problems as well as work of immediate importance was described by its secretary, Sir William Slater. Research is carried out in twenty-three research institutes and units and through some 150 research grants to individuals: this involves an annual expenditure of about £3,000,000. Biologists can be divided into 'naturalists' (or observers) and 'experimentalists'. Both types are needed by the Agricultural Research Council, which employs some 190 'naturalists' and 430 'experimentalists'. It is desirable that a person be well trained as an experimentalist or a naturalist with a general knowledge of the other aspect of his subject, but those poorly trained in both aspects are very difficult to place.

Dr. G. A. C. Herklots (secretary for Colonial Agricultural Research, Colonial Office) described how agricultural research in the Colonies is being developed, and gave details of the work carried out on some problems of considerable economic importance. A Colonial agricultural officer is selected from graduates in biology or agriculture and has two years further training, first in England and then in Trinidad. He then goes to a Colony as an adviser for an area, where he has the assistance of specialists working in a commodity, or a regional, research institute. To assist small Colonies with little or no resident specialists, pools of experts have been established in Britain so that a person can be sent to investigate *ad hoc* problems.

The attainments needed by a person attempting to solve the complex problems arising in applied entomology were given by Dr. W. E. Ripper (Pest Control, Ltd.) as a good knowledge of insect physiology and taxonomy, fair chemistry, some botany and a good grounding in methods. Dr. Ripper looks forward to applied entomology being practised in a manner similar to medicine by a self-governing profession.

The emergence of the antibiotics industry and developments in food processing are considered by Mr. H. J. Bunker (Barclay Perkins, Ltd.) to have accentuated the demand for microbiologists, resulting in favourable prospects of employment for those suitably trained. A biological subject with chemistry as subsidiary is the more desirable combination as a basis for a career in microbiology. Courses, sometimes specialized for a particular field, are offered by a number of universities, but there are as yet insufficient honours degree courses.

---

# STATISTICAL METHOD IN TRANSPORT MANAGEMENT

THE number of suggested definitions of statistics runs into hundreds: many of them are practically indistinguishable one from another, but there have grown up, during the first half of this century, two main schools of thought on the subject. One (with history on its side) regards statistics primarily as the routine and exhaustive compilation of data and their arrangement into tables capable of revealing the required information, if not at a glance, at least without any esoteric mathematical manipulations; the other tends to stress the more modern concept of statistics as the science of drawing, by arguments depending on the theory of probability, generally valid conclusions from particular bodies of data, acquired either by a sampling process or as a product of experiment.

Statistics of the first type has always been an indispensable adjunct to management, whether of a State, a hospital, a factory, or a public undertaking such as the London Transport Executive. More recently, however, the 'small-sample' methods of the second school, developed first for research in biology and later applied to industrial experimentation, have become accepted as potentially valuable tools for managements anxious to investigate not merely the occurrence but also the reasons for the occurrence of observed social phenomena. A public-transport undertaking cannot reasonably hope to run at full efficiency without some knowledge, on one hand, of the social habits and requirements of its potential users and, on the other, of the various changeable factors which may affect such quantities as journey times, fuel consumption, accident-rates, and the useful life of vehicles. These problems have been intensively studied by the London Transport Executive; some results of its sample survey of the travelling habits of the London public were given in the "London Travel Survey"[1], and Mr. F. A. A. Menzler, chief development and research officer of the Executive, has now given, in his paper on "Statistical Methods and Operational Research in Transport", read before the Institute of Transport on November 17, 1952, some examples of the methods in use for the study of routine vehicle operation.

The 'control chart' method, extensively developed during the Second World War for the control of mass-production processes, has many obvious applications in routine management. Mr. Menzler gives examples of its use for investigating weekly failure-rates of various components, including an analysis of puncture-rates in which the control-chart exhibited a periodic fluctuation.

Many investigations have been made of 'passenger habits', some by selective observation, others by actually interviewing a sample of passengers. Habits studied include boarding and alighting at or between stops (the results were used in conjunction with accident statistics to determine the relative dangers of these practices—a nice example of the use of operational research methods to assist in the interpretation of routine statistics), and use of destination blinds. (It appeared that "a substantial proportion rely upon word-of-mouth sources of information, and are mistrustful of notices, maps or posters".)

The standard methods of experimental design, derived to eliminate and allow for the effects of heterogeneous biological material, can be profitably used in dealing with the even more heterogeneous conditions prevailing in transport operation. Mr. Menzler describes, among others, a 'latin square' design used in comparing the fuel consumed by various driving techniques, and a 'cross-over' design used to study the effects of different carburettor settings. Also described is an interesting example of a regression analysis illustrating the amounts by which various causes contributed to an increase in fuel consumption for 1951 over that for 1950.

Mr. Menzler ends by asserting, clearly with reason, that "there are few aspects of transport operation and engineering that might not gain from operational research".

M. R. SAMPFORD

# INHIBITION OF TUMOUR GROWTH BY D-GLUCOSAMINE

By Prof. J. H. QUASTEL, F.R.S.
Research Institute, Montreal General Hospital, Montreal

AND

Dr. A. CANTERO
Montreal Cancer Institute, Notre Dame Hospital, Montreal

THIS article constitutes a preliminary report of our experiments on the effects of D-glucosamine on the inhibition of tumour growth in mice.

Our interest in D-glucosamine arose with the work of Harpur and Quastel[1] on the phosphorylation of D-glucosamine by adenosine triphosphate in presence of hexokinase of brain tissue. Brown[2] showed that this reaction also occurs in the presence of yeast hexokinase, D-glucosamine-6-phosphate being formed. A competition between glucose, fructose and D-glucosamine takes place in brain tissue for the enzyme responsible for the phosphorylation of these sugars[1], the affinities of fructose and D-glucosamine for the enzyme being of the same order and less than that of glucose. Harpur and Quastel[3] then observed that the rate of acetylcholine synthesis in brain extracts is inhibited by the presence of D-glucosamine. This is due to the fact that the process of phosphorylation of D-glucosamine diminishes the amount of adenosine triphosphate available for the acetylcholine synthesis. It thus became clear that the addition of D-glucosamine to a tissue may provide a means of diverting adenosine triphosphate from its normal metabolic paths.

Owing to the fact that the energy required by rapidly proliferating tumour cells for their synthetic processes seems to come largely from the breakdown of glucose and the participation of adenosine triphosphate, it seemed possible that administration of D-glucosamine in sufficiently large quantities into tumour-bearing animals might divert adenosine triphosphate activity sufficiently to affect the rates of the metabolic paths involved in tumour proliferation. Even if the diversion only occurred to a small extent, it might be large enough to impede the rate of proliferation of the rapidly growing tumour cells.

Accordingly, experiments have been carried out during the past two and a half years to observe the effects of the administration of D-glucosamine to mice bearing the tumour sarcoma 37. The results indicate that at concentrations of D-glucosamine which produce no adverse effects on the normal animal, and which give rise to no signs of shock or toxicity, a marked inhibitive effect on the growth of the tumours takes place. The survival-rate of the tumour-bearing animals is practically doubled, while the value for the activity of liver catalase, which is lowered in the presence of tumours, is considerably increased after D-glucosamine administration. It is to be noted, however, that Lustig and Wachtel[4] have examined the effects of a large number of substances of biochemical interest (alkaloids, amino-acids, sugars, amines, and also D-glucosamine) on the development of Ehrlich mouse carcinoma, and reported D-glucosamine to be without effect.

## Experimental Details

*Animals.* Experiments were carried out with mice of the *C.F.W.* strain, as well as with a strain of hybrid albino mice supplied locally. The tumour (sarcoma 37) used was originally obtained from the National Cancer Institute, Bethesda, Maryland. Transplantation of the tumour was carried out by injection, either into the right flank or the right hindquarter of the mouse, of approximately 0·05 ml. of a tumour mash composed of 1 volume of minced tumour tissue diluted with 1 volume of 0·9 per cent sodium chloride solution. This preparation of tumour mash, which was obtained with aseptic precautions, gave a high percentage of successful grafts. The tumours were six days old when they were used for transplantation. They were then usually between 0·5 and 1·0 cm. in diameter, and were well vascularized and showed no necrosis.

Spontaneous regressions were very rare in the animal strains employed once a palpable tumour had been observed, that is, when the inoculant had been successfully grafted and no bacterial contamination had taken place.

*Technique.* Groups of twenty animals, male and female, were used in this investigation, ten animals in each group serving as untreated controls.

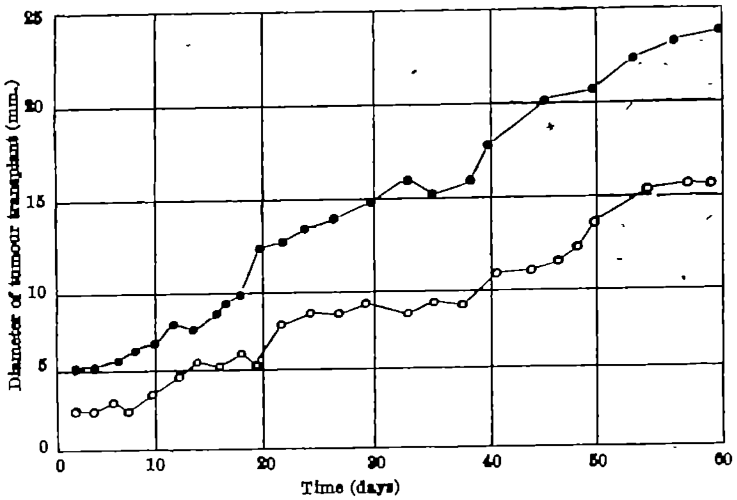
Aqueous neutral solutions of D-glucosamine hydrochloride, or of other substances, were injected intraperitoneally into mice bearing four- to six-day old tumours. Daily injections of either 0·1 ml. (containing 2·5 mgm. D-glucosamine hydrochloride) or 0·2 ml. (5 mgm.) were made and the tumours were examined daily for regression or inhibition of growth. In one group of experiments injections were given the day following implantation of the tumours with subsequent daily injections. The injected mice were carefully compared with equal numbers of control untreated tumour-bearing mice, at least ten animals being used for each test. The animals were usually killed after three weeks and the tumours examined for gross and microscopic effects. Representative slices of the tumours were fixed in Zenker–formol solution, sectioned, and stained with hæmatoxylin-eosin and evaluated histologically.

*Rate of development of sarcoma 37 in C.F.W. mice* (Carworth Farms mice). Typical results showing the effects of D-glucosamine injection on the growth of the tumours are given in the accompanying graph. It is obvious that the administration of D-glucosamine brings about a marked inhibition in the rate of growth of the tumour. At the given rates of admin-

Table 1. MORTALITY OF TUMOUR-BEARING MICE, WITH AND WITHOUT D-GLUCOSAMINE HYDROCHLORIDE ADMINISTRATION

Treatment of the groups of 20 mice in single daily doses started 2–6 days after transplant. The average survival-time for mice treated with D-glucosamine was 70–80 days, whereas that for untreated mice or those treated with glucose was 30–40 days

| Treatment of groups of 20 mice | No. of animals dead 20–50 days following tumour implantation | No. of animals dead 50–100 days following tumour implantation |
|---|---|---|
| Control. No treatment | 20 | 0 |
| 0·1 ml. (2·5 mgm.) D-glucosamine hydrochloride injected daily | 2 | 18 |
| 0·1 ml. (2·5 mgm.) D-glucose injected daily | 19 | 1 |
| 0·2 ml. (5 mgm.) D-glucosamine hydrochloride injected daily | 0 | 20 |
| 0·2 ml. (5 mgm.) D-glucose injected daily | 19 | 1 |



Rate of development of sarcoma 37 in groups of *C.F.W.* mice, with and without D-glucosamine treatment

●, Control mice, after 6-day transplant (ten animals per group); ○, mice, after 6-day transplant, injected daily with 0·2 ml. D-glucosamine hydrochloride (5 mgm.) solution (ten animals per group)

istration of D-glucosamine no complete inhibition of the development of the tumour takes place. A considerable retardation in the development of the tumour mass, however, occurs.

*Mortality of the tumour-bearing mice.* While all the implanted animals die between twenty and forty days following tumour implantation, the majority dying between thirty and forty days, those animals that have been injected with D-glucosamine hydrochloride survive this period and usually do not die until between seventy and eighty days following the implantation of the tumour. Some animals have survived for a hundred days. This has not been found to occur in tumour-bearing animals that have not been treated with D-glucosamine. Administration of glucose instead of D-glucosamine in approximately the same amount has no effect on the mortality-rate of mice bearing sarcoma 37. Typical results of these experiments are shown in Table 1, and indicate the specific activity of D-glucosamine in affecting the survival-rate of the tumour-bearing mice.

*Liver catalase of C.F.W. mice.* As is now well known, the amount of catalase in livers of tumour-bearing mice is lower than that of the normal animals[4-7]. Expressing liver catalase activity in ml. of oxygen produced per second, using the technique of Greenstein and Andervont[6], the liver catalase for normal mice is found to vary between 1·0 and 3·0. The liver catalase, however, of mice bearing sarcoma 37 falls to between 0·1 and 0·5 after forty days following the transplantation of the tumour. When mice bearing sarcoma 37 are injected daily with D-glucosamine solution (2·5 mgm.), the liver catalase activity forty days after transplantation has a value of 1·7. In certain animals, the activity even at seventy-five days is 1·0, and at eighty-five days following transplantation it is 1·2. With mice bearing sarcoma 37, which have been given glucose injections instead of D-glucosamine, the liver catalase activity is not increased.

Table 2. LIVER CATALASE ACTIVITY OF TUMOUR-BEARING *C.F.W.* MICE, WITH AND WITHOUT D-GLUCOSAMINE HYDROCHLORIDE ADMINISTRATION

Activity expressed as ml. oxygen/sec. (Greenstein and Andervont, ref. 6). Results are the average for ten mice (average weight, 23·5 gm.)

| | Activity |
|---|---|
| Normal *C.F.W.* mice | 1·0–3·0 |
| Sarcoma-37 mice after 40 days. (6 days transplant.) No treatment | 0·1–0·5 |
| Sarcoma-37 mice after 40 days. Treated daily with D-glucosamine hydrochloride (5 mgm.) | 1·7 |
| Sarcoma-37 mice after 40 days. Treated daily with D-glucose (5 mgm.) | 0·1 |
| Sarcoma-37 mice after 40 days. Untreated but tumour removed | 1·8 |

It is therefore clear that administration of D-glucosamine to tumour-bearing mice not only results in a retardation of tumour growth but also in a marked diminution of the rate of fall of the catalase activity of the liver. The results given in Table 2 indicate these findings, and show also that the removal of tumours from mice bearing sarcoma 37, after forty days transplantation, also results in an increase of the liver catalase activity.

*Effects of administration of glucose–ammonium sulphate mixtures.* Experiments were carried out to observe whether administration of mixtures of equimolecular quantities of glucose and ammonium sulphate might have effects resembling those of D-glucosamine on mice bearing sarcoma 37. An injection of 2 ml. of a mixture containing 90 mgm. glucose and 67 mgm. ammonium sulphate per ml. into groups of ten mice of mixed sexes was followed by the death of all the animals three days after the injection. Death was due to pulmonary œdema and toxic hepatitis. The minimum lethal dose of the mixture was 0·1 ml. Injection of this quantity into the mice had no toxic effects on sarcoma transplants following ten daily injections. No regression of the tumour mass, nor toxic hepatitis, nor pulmonary œdema was found. Injection of ammonium sulphate solution alone at the minimum lethal dose of 0·1 ml. caused no regression of the tumour mass. Injection of larger quantities—1·0–3·0 ml. of the ammonium sulphate solution—gave rise to toxic effects on lung, liver and kidney. But even in these circumstances no effects on the tumour mass were found during the time that the animals survived.

The results of these experiments seem to indicate that the cytotoxic effects of D-glucosamine on sarcoma 37, and the inhibition of tumour growth, cannot be ascribed to the liberation of ammonia by decomposition of the glucosamine.

*Pathological findings following D-glucosamine administration.* After the injection of D-glucosamine into mice bearing sarcoma 37, there usually appears extensive hæmorrhagic areas in the tumours, which also show some softening. This may occur 24–48 hr. after the initial injection when the tumour shows diffused hæmorrhage.

The microscopic findings resemble the gross findings. Cytotoxic effects, due to D-glucosamine injection, are obvious. The earliest damage is observed after about two hours, when there occurs a shrinkage of the nuclei, retraction of cytoplasm and marked eosinophilia. Between 6 and 8 hr., further degeneration takes place. The nuclei become markedly pycnotic with further cytoplasmic retraction and definite eosinophilia.

At a later stage, there is stasis with more extensive pycnosis and necrosis. This is soon followed by the production of distorted mitotic figures. After 48 hr., normal proliferating cells may be seen frequently at the periphery of the tumour, while cellular disintegration is observed in the severely affected portion.

The necrosis is followed later by autolysis, the supporting structure is destroyed and only a few abnormal cells, mostly near the periphery, can be distinguished. The tumour decreases in size but no complete regression has been noted.

*Effects of* D-*glucosamine administration to normal animals.* No toxic effects, or signs of shock, have been noticed when D-glucosamine, in the quantities mentioned, are injected intraperitoneally into normal mice.

A routine histological examination of all animals treated with D-glucosamine has shown that no abnormal effects are present in the liver, spleen, kidneys, suprarenals, or the intestinal mucosa of the animals. Blood counts (red and white cells) of both normal mice and tumour-bearing mice are unaffected by D-glucosamine administration.

Too few experiments have yet been carried out to discover whether injections of high concentrations of D-glucosamine will bring about abnormal changes in the animal tissues. So far, we have observed no toxic symptoms in normal animals following D-glucosamine injections.

## Conclusions

The observations recorded indicate that the administration of D-glucosamine to mice bearing the tumour sarcoma 37 results in a marked inhibition of the rate of growth of the tumour and in the development of cytotoxic effects in the tumour itself. No complete regression of the tumour has been observed under our experimental conditions, but the results indicate a marked specificity of action of the substance on the tumour mass as compared with that on the host tissue. Many substances are now known to have cytotoxic effects on tumours, but it is the relative inactivity of D-glucosamine on the host tissue which is a striking feature. The fact that the liver catalase activity does not diminish to the same extent in animals that have been treated with glucosamine as in those that have not been so treated is in agreement with the pathological findings. The survival-rate of tumour-bearing mice treated with D-glucosamine is considerably greater than that of untreated animals, and gives rise to the hope that D-glucosamine (or its derivatives) may represent a substance with distinct chemotherapeutic possibilities.

It is significant that D-glucosamine was investigated because of its ability either to compete with glucose in its initial reactions with adenosine triphosphate, or to divert the latter substance from its normal metabolic pathway in tumours. The cytotoxic effects of D-glucosamine on sarcoma 37 do not necessarily mean that the substance is behaving in the manner that has been pictured. The results do indicate, however, that this line of approach may be well worth following up. It seems to us very possible that D-glucosamine derivatives or analogues may be found which are much more effective than D-glucosamine itself, and that these substances, while having relatively little effect on the host tissue, may bring about marked changes in the rate of development of the tumour. Very recent experiments of Ikawa *et al.*[8] seem to indicate that certain polysaccharides having tumour-inhibiting properties possess D-glucosamine as part of their structure.

We are grateful to the National Cancer Institute of Canada for grants which have made this work possible. [Dec. 11.

# FLUOROMETRIC ANALYSIS OF URINARY STEROIDS

By Dr. M. FINKELSTEIN

University College of Swansea, University of Wales, and the Hebrew University, Jerusalem

The study of the metabolism of œstrogenic hormones was made difficult by the lack of suitable quantitative methods for the determination of the three naturally occurring œstrogens, namely, œstradiol, œstrone and œstriol, and of their metabolites.

To meet this difficulty in part, with the collaboration of Drs. Hestrin and Koch, I elaborated, some years ago, a fluorometric method for the quantitative determination of crystalline œstrone, œstradiol and œstriol[1]. This method was based on the old observation of Wieland, Straub and Dorfmueller[2] and of Marrian[3] that these œstrogens when heated with sulphuric acid develop a bluish-green fluorescence. We have found, however, that sulphuric acid was not suitable for quantitative determination, because high and irregular blank readings were encountered and the reproducibility of the results was unsatisfactory. Phosphoric acid, on the other hand, showed only negligible blank readings, and by taking suitable precautions a linear relationship between the concentration of any of the œstrogens and of the fluorescence intensity was obtained.

As the ultimate object of our study was to adapt this method for the determination of the œstrogenic hormones in urine and blood, attempts were made to make use of existing partition methods for the urinary œstrogens and to apply the fluorometric measurements to the purified fractions. However, it soon became evident by comparison of the fluorometric results with bioassay and also from recovery experiments that the fractions under investigation contained some substances, different from the œstrogens, which interfered with the fluorometric readings. This led us to re-investigate the partition procedure and, as a result, a modified partition method was developed[4]. The accompanying chart shows schematically the course adopted; crude extract has thus been divided into three fractions: (1) œstrone–œstradiol fraction, (2) œstriol fraction, and (3) neutral water-soluble fraction. Recovery experiments using this partition procedure gave satisfactory results both in the œstrone–œstradiol and in the œstriol fraction. As little as 20 γ of any of these œstrogens added to 1 litre of urine could be determined with an accuracy of ± 20 per cent. Comparison of results obtained by bioassay and fluorometry performed on several samples of preg-

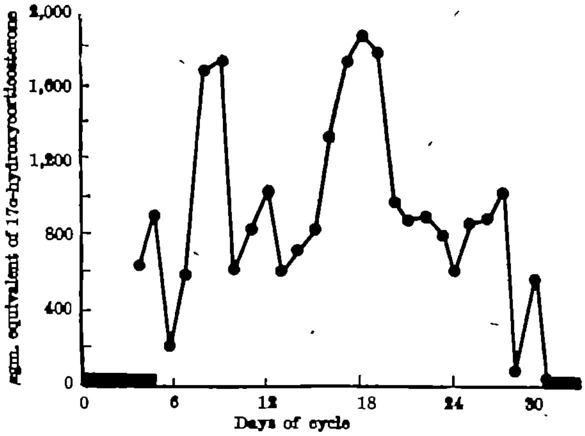
nancy urine showed good agreement in respect of concentrations of oestrone and oestriol. Urine of normal menstruating women yielded also a comparable result by both methods. On the other hand, fluorometric analysis of normal male urine consistently furnished values of oestrone about five times higher than the values obtained by bioassay. We have also obtained the same ratio when analysing urine of two female pseudohermaphrodites. It seems to us that in both cases we are dealing with one substance, which may prove to be a metabolite of the oestrogens.

With regard to the neutral water-soluble fraction, we have observed that it also contains some substance, or substances, which on treatment with phosphoric acid give rise to fluorescence. This fluorescence was usually somewhat more intense in the case of male urine than in normal female urine. Calculated in terms of 17-hydroxycorticosterone, the mean excretion of the fluorogenic material was about 1,300 γ/litre in the case of male and about 800 γ/litre in female urine. With the collaboration of Miss Berlin, we have carried out daily analyses of female urine throughout the menstrual cycle. Two peaks in excretion were usually observed: one at about the tenth day of the cycle and the second at about the twentieth day (see graph). Urine of postmenopausal women did not show these cyclic changes, but day-to-day fluctuations were recorded.



Excretion of the neutral fluorogenic substance during a menstrual cycle

A very pronounced increase in the excretion, about five times higher than in the normal female, was found in the case of the two female pseudohermaphrodites previously mentioned[4]. The excretion of the fluorogenic material in these cases was 4,000–5,000 γ per litre urine, and was fairly constant. The urine of these patients seemed to us to be a good source for isolation purposes, and accordingly we carried out the extraction and partition of about 100 litres of urine. The neutral water-soluble fraction was sent to Prof. T. Reichstein; he isolated three crystalline compounds, one of which showed the characteristic fluorescence. Work on the identification of these compounds is now in progress in Prof. Reichstein's laboratory in Basle.

In addition to the two female pseudohermaphrodites, we have found thus far an increased excretion of the fluorogenic substance in one case of arrhenoblastoma, and constantly in late pregnancy urine. There it amounts to about 2–4 mgm. per litre urine. Injection of 300 mgm. adrenocorticotropic hormone in daily doses of 100 mgm. resulted also in a fourfold increase over the control period.

Since some corticosteroids also produce fluorescence on being heated with phosphoric acid, the question arose whether the increased excretion might be attributed to their presence in the neutral water-soluble fraction. Parallel determination of urinary extracts for corticosteroids and for the fluorogenic substance did not result in a positive correlation.

In the case of the two pseudohermaphrodites, the excretion of corticosteroids was either within normal limits or only very slightly elevated, whereas the fluorometric values were much above 'normal'. In cases of the Cushing syndrome and in several cases of hirsutism and virilism, excretion of corticosteroids was increased, whereas excretion of the fluorogenic substance was unchanged. A marked increase in excretion of both corticosteroids and the fluorogenic substance was observed only in late pregnancy urine.

Isolation studies have been undertaken in order to determine whether the excretion of the fluorogenic material in the cases cited here consists of one and the same compound, or whether we are dealing with several fluorogenic compounds.

I would like to express my thanks to the staff of the Hormone Research Laboratory of the Hebrew University for their collaboration, and to Prof. Bernhard Zondek for his guidance during the performance of these experiments. My thanks are also due to Prof. C. W. Shoppee, University College, Swansea, for his valuable suggestions made in the course of the preparation of the manuscript. [Sept. 12.

## Effects of Daily Irradiation by Fast Neutrons on Male Fertility

SINCE January 1, 1951, the smaller pile at Harwell has been used for irradiating *CBA* mice daily with fast neutrons. These were fission neutrons obtained by allowing thermal neutrons escaping from the graphite reflector to interact with uranium on the floor of the compartments in which the animals were housed. It is believed that less than 5 per cent of the biological effects produced was due to contaminating radiations. Dose-rates were measured with homogeneous 'tissue' ($C_{0\cdot18}$ $H_{1\cdot00}$ $N_{0\cdot04}$ $O_{0\cdot48}$) and hydrocarbon (CH) ionization chambers, an allowance being made for gamma-ray ionization by simultaneous readings with an argon chamber[1].

The purpose of this preliminary report is to record the unexpected sensitivity of the mouse testis. A dose of 70 rep. at the weekly dose-rate of 8·3 rep. reduced the fertility of *CBA* mice to half that of controls, using a standard mating test in which the test male is left for four nights with four *CBA* females aged 2–5 months. An accumulated dose of 100 rep. halved the average weight of the testis, and after the same dose there has been no recovery of fertility at any time right up to the age at which unirradiated controls become naturally sterile.

In contrast, the female *CBA* mouse was less sensitive to the sterilizing effects of fast neutrons. An accumulated dose of 140 rep. in seventeen weeks did not seem to affect the ability to conceive or produce young.

The difference in sex sensitivity is opposite to that usually accepted for X- and gamma-rays[2], and the low dose for absolute sterilization in males is also noteworthy[3]. The dose-rate which produced such striking testicular damage had no effect on growth-rate or body-weight for thirty-five weeks, produced no great hæmatological changes by the time the male mice were permanently sterile, and did not appear to produce cataracts until some time after considerable losses in weight occurred.

## Electron Microscope Studies of the Structure of the Influenza Virus

FROM studies of the growth-cycle of influenza virus, Hoyle[1,2] formed the hypothesis that the virus elementary body consisted of an aggregate of smaller units, and Burnet and Lind[3] arrived at a similar concept from studies of virus variation. Hoyle[2,4] showed that the virus could be disintegrated by shaking with ether, with the production of separate red-cell agglutinating and complement-fixing particles of smaller size than that of the elementary body.

Fig. 1

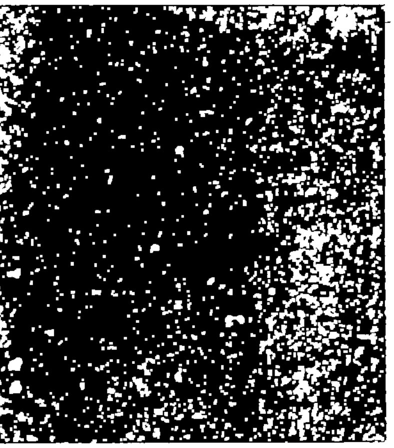

Fig. 2

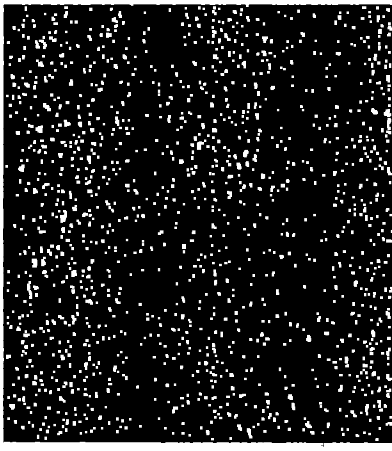

Fig. 3

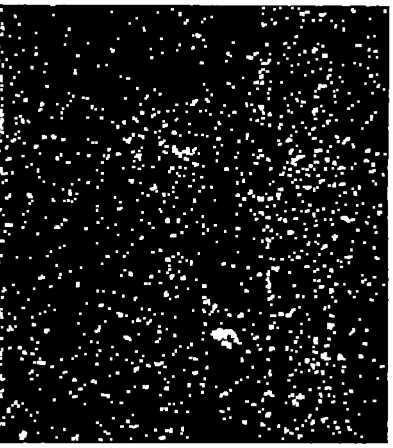

Fig. 4

A concentrated suspension of *DSP* strain of virus *A* was prepared as described by Hoyle[4] from infected allantoic fluid by adsorption on and elution from chick-embryo red cells. The preparation was fixed with osmic acid, and electron micrographs at an instrumental magnification of 7,500 were taken of drops on collodion-filmed grids, which were first drained, dried and washed with distilled water, then dried again and shadowed with chromium. Fig. 1 is an enlarged negative print showing elementary bodies of average size about 1250 A., together with smaller particles ranging from about 100 A. to 500 A. Many of the elementary bodies have a roughly hexagonal outline.

The elementary bodies observed in infected allantoic fluid appear to be released from the cells of the chorio-allantoic membrane by a process of cytoplasmic disintegration; but a similar disintegration may occur in normal cells, with the result that particles of cytoplasmic origin are found also in normal allantoic fluid[2]. Fig. 2 shows an electron micrograph of a preparation made from uninfected allantoic fluid. Large particles are present; but they are rather smaller than the virus elementary bodies, and are more flattened and less regular in outline. These particles may be derived by disintegration of the cytoplasm of desquamated chorio-allantoic membrane cells present in normal allantoic fluid. They do not agglutinate red cells.

When the suspension of *DSP* virus was shaken with ether and then incubated overnight, the elementary bodies were completely disintegrated and the ether-treated suspension showed only a great number of small particles ranging from about 100 A. to 500 A. By adsorption with red cells this suspension could be fractionated into two components: a red-cell agglutinating fraction recoverable from the red cells by elution, and a complement-fixing fraction not adsorbed by the cells. The properties of these fractions have been described[4].

Fig. 3 is an electron micrograph of the complement-fixing 'soluble antigen' fraction. It shows numerous small particles mostly of size about 120 A. There is also a fair number of about twice that size; but larger particles are very infrequent. Filtration of the preparation through a 'Gradocol' membrane of average pore diameter 300 A. removed both the particles and the complement-fixing antigen.

The red-cell agglutinin fraction (Fig. 4) shows a greater range of particle sizes. Numerous particles of about 120 A. are present; but there are also many others of larger size, notably about 500 A. Adsorption of the preparation with red cells removes both the smaller and larger particles, and both can be recovered by elution.

The concept that the influenza virus elementary body consists of an aggregate of smaller units is therefore supported by electron microscope studies. It seems clear that the particles seen in the electron micrographs include those that carry the biological properties of the two fractions, and moreover the indications are that both the red-cell agglutinin and the complement-fixing antigen have a particle size of about 120 A., the larger particles being probably aggregates.

## Application of the Quantum Hit Theory to Tumours Induced by Ultra-violet Radiation

WE have previously described the application of the quantum theoretical hit theory to tumours induced by carcinogenic hydrocarbons[1] and by viruses[2]. We have now applied the theory also to skin tumours induced by ultra-violet radiation.

In the experiments of Blum, Grady and Kirby-Smith[3], several groups of mice were irradiated with various doses, $D$, of ultra-violet light, given at different regular intervals of time, $t_i$. The mean induction time, $\bar{t}$, between the first irradiation and the appearance of the first tumour was measured as a function of $D$ and $t_i$. According to our theory, the variation of $\bar{t}$ with $D$ and $t_i$ should follow the expression:

$$\bar{t} = \frac{t_i}{k_e D} + T. \qquad (1)$$

Here $k_e$ and $T$ are two constants, the former denoting the probability per unit time and unit dose of an excitation of a cell by the ultra-violet radiation, the latter denoting the mean time of growth of a tumour from the time of excitation to the time at which the tumour has grown sufficiently to be palpable or visually detectable. From (1) we see that if $\bar{t}$ is plotted against $1/D$, we should get straight lines cutting the ordinate axis in the common point $(0,T)$ and having slopes proportional to $t_i$ with the proportionality factor $1/k_e$. In Fig. 1 we give for $t_i = 1 \cdot 0$, $1 \cdot 4$ and 7 days, respectively, the experimental mean induction times (in days) as found by Blum, Grady and Kirby-Smith, which are seen to cluster around three straight lines.

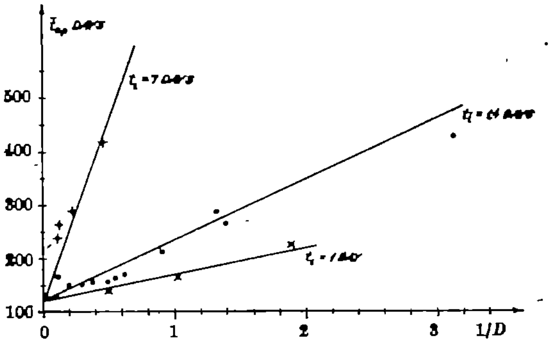

Fig. 1

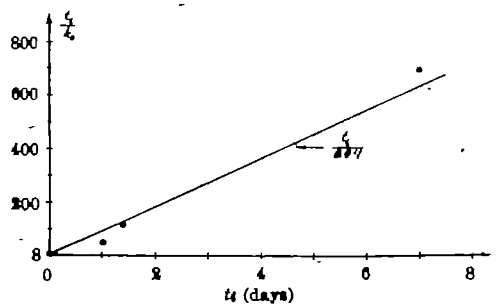

Fig. 2

In Fig. 2 we have plotted the slopes of these lines against $t_i$, and it is seen that they lie about a common straight line corresponding to $k_e = 0 \cdot 011$. Thus the experimental findings of Blum, Grady and Kirby-Smith are in satisfactory agreement with our theory, and consequently they give new and independent evidence for the applicability of the quantum hit theory to the problem of the mechanism of carcinogenesis.

A detailed account of the application of the quantum hit theory to tumours induced by ultra-violet radiation, including the theoretical deduction of the incidence versus induction time curves, will shortly be published (*Acta Path. et Microbiol. Scand.*).

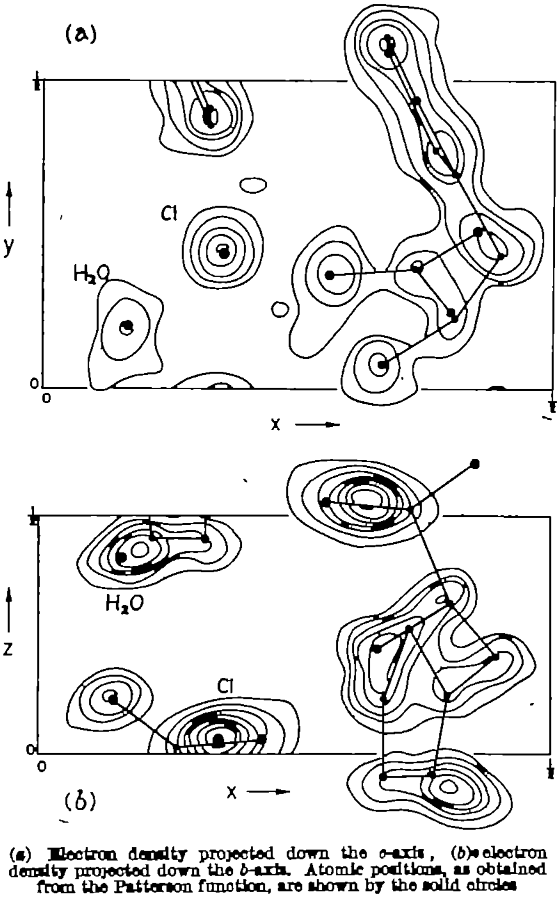
## Crystal Structure of Histidine Hydrochloride Monohydrate

Crystals of the hydrochloride monohydrate of the important amino-acid histidine can be obtained as rather thick tablets by evaporation of aqueous solutions containing a little hydrochloric acid. X-ray examination shows that the crystals are orthorhombic, with unit cell edges $a = 15{\cdot}36$ A., $b = 8{\cdot}92$ A. and $c = 6{\cdot}88$ A. The space group is $P2_12_12_1$, and there are four molecules in the unit cell. The structure was obtained from a three-dimensional Patterson function which was interpreted by means of the vector convergence method[1].

The atomic parameters as indicated by the vector convergence diagram were adjusted somewhat in order to improve the agreement of the calculated interatomic vectors with observed Patterson peaks. The structure factors of the three prism zones were then calculated; the average discrepancy, $R$, for the 256 observed reflexions was 27 per cent. The structure factors of 170 of these reflexions were then treated by the method of least squares[2]. Shifts in the atomic parameters averaging 0·06 A. were obtained.



(*a*) Electron density projected down the *c*-axis, (*b*) electron density projected down the *b*-axis. Atomic positions, as obtained from the Patterson function, are shown by the solid circles

Plots of the electron density projected down the *c*- and *b*-axes were then prepared, by use of 89 of the 121 observed ($hk0$) reflexions and 57 of the 98 observed ($h0l$) reflexions respectively. The resulting maps are reproduced herewith. Contours were drawn at equal arbitrary intervals, except about the chlorine atoms, where they are drawn at half that interval. The atomic shifts suggested by these plots are in fairly good agreement with those obtained from the least-squares treatment.

From the degree of resolution in these projections it is doubtful whether the structure in three dimensions could have been obtained from them alone. On the other hand, once having determined the structure from the Patterson function, it is probable that a satisfactory refinement can be achieved without recourse to laborious three-dimensional Fourier and least-squares analyses, which involve complex structure factors.

The parameter refinement has been temporarily postponed, and since at the present stage of the work the standard error in a parameter is about 0·05 A., any discussion of the structure, such as which of the many tautomeric forms of the imidazole ring is present in the crystal, the precise dimensions of this heterocyclic ring, and the nature of the hydrogen bonding, must be deferred. At present, nevertheless, it is established that the histidine molecules in the crystal do not assume an extended configuration, but tend rather to curl back on themselves—a situation which may arise from significant attraction between the carboxyl group and the imidazole ring.

This work was carried out under Contract Nonr-220(05) with the Office of Naval Research.

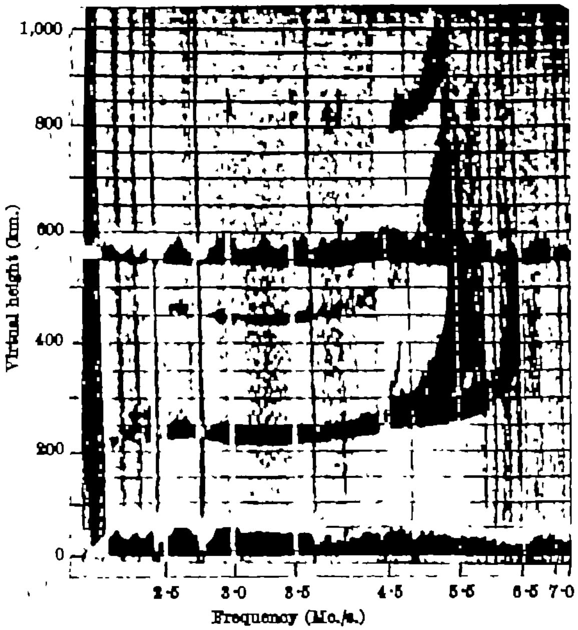
## Angle of Arrival of Z Echoes

It has been suggested by Scott[1] that uncoupled *F*-region *Z* echoes are due to longitudinally propagated waves reflected from an area near the magnetic zenith.

Measurements of the angle of arrival of *Z* echoes have recently been made at Hobart (geomagnetic latitude 51° S., dip 72°) in order to test this suggestion. The mean direction was found to be in the magnetic plane 7·8° north of the vertical. Thirty-four measurements were made between July 13 and August 3, 1952, on a frequency of 4·65 Mc./s. In all cases the *Z* echoes were observed during the late afternoon, the height of reflexion being between 170 km. and 210 km.

According to Scott's hypothesis, a collision frequency of about $1{\cdot}5 \times 10^5$ per sec. would be needed to explain the observed angle. This is inconsistent with previous estimates of collision frequency, which suggest that it is about $10^4$ per sec. at 200 km.



I wish to thank the Electrical Engineering Department of the University of Tasmania for the provision of facilities and assistance in building the apparatus, and also the Radio Research Board of the Commonwealth Scientific and Industrial Research Organization for a grant in aid of the investigation.

## Reflexion Coefficient of Radio Waves from Frozen Terrains

During the period January–February 1952, measurements were made in northern Canada in order to determine the reflexion coefficient of radio waves for normal incidence from deeply frozen land or sea. The frequency used was 1,600 Mc./s.

The method of measurement was to transmit a linearly polarized pulse signal vertically downwards from an aircraft flying at heights between 10,000 ft. and 20,000 ft. and to receive the signal re-radiated from the ground on a suitable receiver in the aircraft. Attenuation was inserted in the aerial lead of the receiver to maintain a constant received signal strength as the reflexion from the ground varied. The loop gain of the equipment was checked periodically to confirm that the performance of the equipment remained unchanged during the measurements. In addition, the signal was compared, whenever possible, with reflexions from open-water leads in Hudson Bay or the Great Lakes shortly before or after the measurements over the terrain in question. This was used as a standard for comparison.

It had been believed that the smallest reflexion coefficients likely to be met would not be lower than that from dry desert sand. This had already been checked over the shifting sand dunes of the Sinai Desert and also in desert areas in North Africa. The measurements agreed quite well with figures quoted previously by other authorities.

The reflexion coefficient from frozen muskeg and from the barren gravel areas north of the tree line in Canada was found to be roughly equal to that from dry sand. The frozen ice on Hudson Bay also gave a similar result. The ground temperatures were below − 35° F., and the ground and sea were frozen to a depth of several feet.

When flying over deeply frozen land where the land was heavily wooded, the land being covered with loose snow several feet deep and the trees thickly covered with snow and ice, a reflexion coefficient appreciably less than that from muskeg was observed. This was checked in two or three different areas, and the same figure was obtained on each occasion.

The figures of received signal power as compared with a sea reflexion were − 13 db. for sand, frozen muskeg or gravel, etc., and − 20 db. for frozen snow-covered forest. The accuracy of measurement was not worse than ± 2 db. The reflexion coefficient of sea water has been measured by other observers and is 0·83. Using this figure, the reflexion coefficients for various frozen terrains have been calculated and are as follows:

| Terrain | Reflexion coefficient |
|---|---|
| Sea | 0·83 |
| Deep ice on sea | 0·20 |
| Frozen muskeg or barren gravel | 0·20 to 0·25 |
| Frozen lakes | 0·25 |
| Frozen snow-covered forest | 0·08 |

## Light Scattering by very Stiff Chain Molecules

Very precise light-scattering measurements by B. H. Bunce[1] on several thymonucleic acid preparations have shown that the scattering function of these gigantic macromolecules—the molecular weights are between 2·6 and 6·7 millions—differ remarkably from that of a random coil. The angular dependence of the reciprocal reduced intensity $1/P = I(0)/I(\vartheta)$, for all samples, reveals that the molecules are not perfectly coiled. The experimental points are situated between the curves for a random coil and that for a stiff rod.

Therefore it seemed worth while to compute the scattering function for a thread-like molecule of finite length with variable flexibility. In some previous work on viscosity and sedimentation[2] of such relatively short molecules, the usual 'pearl-necklace' model was chosen. By variation of the valency angle $\alpha = 180° - \beta$ between two consecutive links and the length of link $b$, all kinds of flexibility from the stiff rod ($\cos\beta = 1$), to the quite soft thread ($\cos\beta = 0$), can be represented. This model is not very suitable for the consideration of light scattering; it can be replaced by the 'thread' model with continuous mass distribution and curvature, introduced by Kratky and Porod[3] in the theory of X-ray scattering.

The measure of the flexibility is the persistence length $a$, the average value of the projection of an infinitely long thread on the tangent at one end of the thread : $a = b/(1 - \cos\beta)$.

This model fits much better the conditions for the scattering of visible light than for X-rays, as the fine structure of the macro-molecule, that is, the linking of the monomers, does not matter compared to the wave-length of some 1000 A.

According to Kratky and Porod, two thread elements, $dl_1$ and $dl_2$, separated by the length $l_{12}$ of the chain, on the average give rise to a scattered intensity proportional to

$$\exp - k^2s^2R^2{}_{12}/6,$$

where $k = 2\pi n/\lambda$, $s = 2\sin\vartheta/2$, $R^2{}_{12} = 2a^2(x_{12} - 1 + \exp - x_{12})$, $x_{12} = l_{12}/a$, provided the distribution-function of their mutual distance $r_{12}$ does not differ too much from the Maxwellian. This does not apply to the stiff rod, $x = 0$, and is also a bad approximation for small values of $x \sim 1$, but gets rapidly better with increasing $x$.

With this simplification, the scattering function for the molecule reads :

$$P(\vartheta) = \frac{1}{L^2}\int_0^L\int_0^L \exp(-k^2s^2R^2{}_{12}/6)\,dl_1\,dl_2 =$$

$$\exp p\left[F(p,x) - \frac{p}{1!}F(p+1,x) + \frac{p^2}{2!}F(p+2,x)\ .\ .\ .\right],\ x \gg 1,$$

with

$$F(p,x) = \frac{2}{(px)^2}(px - 1 + \exp - px)\quad p = k^2s^2a^2/3.$$

The accompanying graph shows $1/P(\vartheta)$ for various values of $x$, where the variable

$$v = 3p\left[\frac{x}{3} + F(1,x) - 1\right] = A(a,x)\ .\ \sin^2\frac{\vartheta}{2}$$

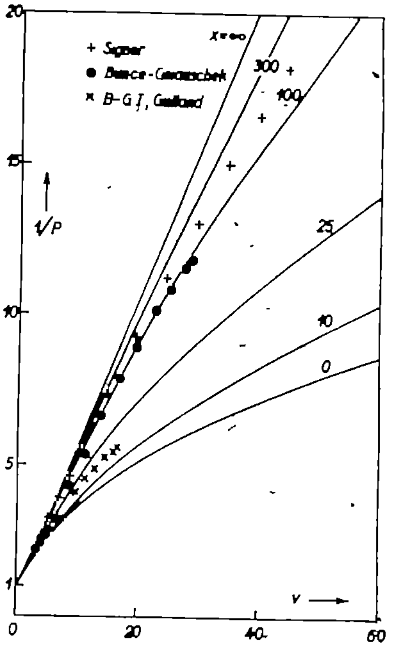
is chosen in such a way that the initial slope is the same for all curves. The curve $x = 0$ is the known scattering function for rods. Even at very large values of $x$, the limiting curve $x = \infty$ is not reached. In fact, the deviations are quite noticeable at as large a value as $x = 300$.

The experimental data of Bunce on various samples fit into this picture very well. The following dimensions may be deduced :

| Sample | $M$ | $x$ | $a$ | $L$ | $R$ | $M/L$ |
|---|---|---|---|---|---|---|
| Present writer | $6{\cdot}7 \times 10^6$ | 150 | 287 A | 43,000 A. | 4950 A. | 156 M.U./A |
| Bunce–Geiduschek | 4·0 | 100 | 263 | 26,300 | 3750 | 152 |
| Bunce–Geiduschek degraded* | 2·64 | 16 | 541 | 8700 | 2970 | 305 |
| Gulland | 4·0 | 16 | 541 | 8700 | 2970 | 462 |

* The sample had been left for 20 hr. in an acid solution of $p$H 3·0.

In the first two samples, the structure of the thymonucleic molecule seems to be very similar, the persistence length $a$ being markedly the same in both. The last two samples also agree completely with each other in their geometrical dimensions. The large value of $a$ signifies that the coil is twice as extended. The overall length, however, is much smaller than that of the first two samples. Hence, the mass density $M/L$ is increased to 305 and 462 M.U./A. The shortening of the chain may be the consequence of an internal association of neighbouring chain segments. The additional linkages coupled with the increased density evidently stiffen the molecule and yield a more extended coil. Very careful preparation may prevent such an internal association, which takes place also on degradation in acid solutions.



Reciprocal reduced intensity, $1/P(\vartheta)$, plotted against $v = A(a,x)\,.\,\sin^2\vartheta/2$. The experimental points for the Gulland and Bunce–Geiduschek degraded samples coincide

## 'Newtonian' Time in General Relativity

A result recently given by Eisenhart[1] suggests an interesting application in general relativity. According to it, we can choose co-ordinates in which a line element showing spherical symmetry would take the form :

$$ds^2 = -r^2(d\theta^2 + \sin^2\theta d\varphi^2) + \gamma dt^2 + 2\alpha dr dt,\quad \gamma = \gamma(r,t),\quad \alpha = \alpha(r,t) \qquad (1)$$

and a radial null vector $w^\mu$ will have $w^2 = w^3 = w^4 = 0$, so that the velocity of light along radial directions (given by $w^1/w^4$) is infinite. Hence we may call the co-ordinates $(r,t)$ the 'Newtonian' co-ordinates.

Several well-known solutions in general relativity take up very simple forms when expressed in these co-ordinates. Schwarzschild's exterior solution has :

$$\alpha = 1,\quad \gamma = 1 - 2m/r. \qquad (2)$$

Here $m$ is the constant giving the mass of the particle at the origin. If, however, we take $m$ to be an arbitrary function of $t$, the same solution will represent the gravitational field of a radiating star found by us[2], thus showing that our solution of a non-static mass is the natural generalization of Schwarzschild's solution for a static mass.

Again, for describing the field of a mixture of matter and flowing radiation within the interior of a star, where the energy-tensor is of the form[3]:

$$T_{\mu\nu} = (p + \rho)v_\mu v_\nu - p g_{\mu\nu} + \sigma w_\mu w_\nu,$$
$$v_\mu v^\mu = 1, \quad w_\mu w^\mu = 0, \qquad (3)$$

we can choose co-moving Newtonian co-ordinates in which $v^1 = v^2 = v^3 = 0$, $w^2 = w^3 = w^4 = 0$. We shall then find that:

$$T_1^{\,1} = T_2^{\,2} = T_3^{\,3} = -p; \quad T_4^{\,4} = \rho. \qquad (4)$$

These relations are the same as the familiar relations for static solutions. Of course, here, $T_1^{\,4} \neq 0$.

Recently, we have found that even in the unified field theories described by a non-symmetrical $g_{ik}$, co-ordinates of this type introduce a great deal of simplification in problems involving radiation flow. Details of this investigation are awaiting publication elsewhere.

## Serological Relationships of Hyrax and Elephant

ORIGINALLY classed with the Pachyderma, the hyraxes (rock rabbits or conies) have in turn been placed in the orders Rodentia and Perissodactyla. More recently, they have been placed in a separate order, the Hyracoidea[1]. It is, however, still open to discussion whether there is not a relation between hyrax and elephant; one of the more recent contributions on the subject is based on the similarity of the placental formation in animals of the two orders concerned[2].

In the course of some recent work on the development of the use of precipitating antisera for the identification of blood meals of tsetse flies and other African blood-sucking arthropods, an antigenic relationship between elephant and hyrax has been observed. Serological relationships have been noted by various workers between related animals of many different species since the original work of Nuttall[3] on this subject. Qualitative determinations made by the ring test have been shown to be valid, providing the antisera used in the reaction are devoid of non-specific antibodies. Before absorption, antisera prepared in rabbits by repeated injections of alum-precipitated serum give reactions at a high titre with the serum of all the mammals which were tested and which included representative samples from most orders[4].

Two antisera were prepared in rabbits by the repeated injections of alum-precipitated sera of the Indian elephant (*Elephas elephas*) and hyrax (*Heterohyrax syriacus prittwitzi* Brauer) respectively, and both antisera gave positive reactions at high titre with the sera of all mammals which were tested. Each antiserum was then absorbed with the sera of man, ox, sheep, horse, pig, dog and cat in the proportions necessary to remove the corresponding antibodies. These absorbed antisera were then re-tested as before with the sera of a wide range of species of mammals and were found to react only with elephant and hyrax in both cases. The anti-elephant serum reacted at a titre of 1 : 64,000 with elephant serum and at 1 : 32,000 with hyrax serum, while the anti-hyrax serum reacted at a titre of 1 : 16,000 with hyrax serum and at 1 : 8,000 with elephant serum.

These observations, which were similar to those previously made with known related mammals, indicate a very marked relationship between the sera of hyrax and elephant; they are also of interest in relation to the taxonomic position of the Hyracoidea.

I am grateful to the Zoological Society of London for supplying the elephant serum, and to T. C. S. Morrison Scott for identifying the species of hyrax.

## Assessment of Consciousness during Curarization

MODERN surgical techniques and experimental methods make increasing use of muscular relaxants combined with anæsthetics to produce the optimum conditions for surgery. This practice leads to certain difficulties in assessing consciousness, since the usual muscle reflexes are impaired by the action of the relaxant. The change in heart-rate in response to a pain stimulus has recently been investigated and found to be a reliable indicator of consciousness during electrical curarization in animals, and during ether anæsthesia in man[1]. It therefore seemed possible that this cardiac pain reflex might be useful as an index of consciousness when muscular relaxants were being used.

'Flaxedil' was injected intravenously into rabbits so that the voluntary muscles were paralysed, and the heart-rate was recorded continuously on one channel of an electro-encephalograph machine; the pain stimulus consisted of a pin-prick on the nose of the animal. This stimulus resulted in an increase in the heart-rate which varied from 9 to 14 per cent with different individuals and lasted for about thirty seconds; the cardiac pain reflex before injection was similar in size and duration, but during light anæsthesia it was reduced, and in surgical anæsthesia it was abolished.

The pupillary reflex to light, which can sometimes be used when voluntary muscle is paralysed, is not easy to observe after injection of 'Flaxedil' because ptosis and nystagmus occur. If a suitable heart-rate indicator is available, or could be designed, it might now have considerable practical application in human and veterinary surgery when curarizing drugs or new anæsthetics are being used.

## Chromosomal Re-arrangements in the Progeny of *Drosophila* Males treated with Mustard Gas

WHEN *Drosophila* males are treated with mustard gas, the proportion of chromosome re-arrangements to sex-linked lethals in their progeny is lower than after an X-ray treatment which yields the same frequency of sex-linked lethals. This observation has been made by genetical methods[1]. It has been confirmed by the cytological findings of Slizynska and Slizynski[2], who examined the salivary chromosomes of strains carrying sex-linked lethals induced by mustard gas and reported that these chromosomes had many fewer structural changes than would have been expected if the lethals had been induced by X-rays. Since these investigations were based on selected samples of chromosomes—namely, *X*-chromosomes already shown to carry a lethal—it seemed important to check them on unselected samples. Accordingly, wild-type *Drosophila* males were given different doses of mustard gas, and unselected female $F_1$ larvæ were analysed for chromosomal changes in their salivary glands. The apparatus for the treatment was designed by Dr. H. Moser and has been described elsewhere[3]. The genetical effectiveness of each dose was measured in terms of sex-linked lethals. For comparison, exposures were carried out with doses of X-rays which approximately matched those of the mustard gas in respect of their ability to produce sex-linked lethals. The results are summarized in the accompanying table.

The observations bear out the previous genetical and cytological findings. In the overall result, as well as at each dosage-level, there is a marked shortage of re-arrangements in the mustard-gas series as compared with the X-ray one. The overall difference between 7·6 per cent re-arrangements in the X-ray series and 1·3 per cent in the mustard gas series is significant at the 0·1 per cent level. The results are not sufficient to decide whether, as the table suggests, the ratio between the two frequencies tends to shift in favour of irradiation as the dose is increased. If this should be true, it would indicate a difference in the mechanisms by which these two mutagenic agencies produce re-arrangements. Experiments to test this point are under way in this department.

A point worth noting is the occurrence of two reversed repeats among the eleven chemically induced structural changes. No repeat occurred among the forty-eight radiation-induced changes; in general, repeats appear to be rare after radiation treatment. The occurrence of two of them in a very small sample of chemically induced changes is remarkable. It is, however, in line with the observation made by Auerbach[4] that a high proportion of visible mutations induced by mustard gas occur first as mosaics in the progeny of treated males; for repeats, like mosaics, are changes which must have arisen after the treated chromosome had separated into its daughter chromatids.

FREQUENCY OF LARGE CHROMOSOME RE-ARRANGEMENTS AFTER DIFFERENT DOSES OF X-RAYS AND OF MUSTARD GAS

| Expt. | X-rays | | | | | | Mustard gas | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | % sex-linked lethals | No. larvæ examined | No re-arrangements | | | | % sex-linked lethals | No. larvæ examined | No. re-arrangements | | | |

## Chemical Constitution of the *L*-Forms of Bacteria

THE *L*-forms of bacteria, a study of which has been described recently[1], are dwarf organisms derived from a complex transformation of bacteria, either spontaneously or under various noxious influences. Their morphological as well as biological characters are so different from those existing in the bacteria they are derived from that it seemed interesting to us to compare the chemical constitution of these two forms of the same organism.

The material used for our chemical study was *L*-forms of *Proteus* (*P* 18), three to four weeks old, grown on a liquid medium[2]. The *L*-forms are separated from the medium by centrifugation, washed twice in physiological serum, then in distilled water, concentrated by centrifugation at 12,000 r.p.m. and resuspended in distilled water. It is emphasized that this material is not absolutely homogeneous. It consists of a mixture of about 80 per cent of *L*-forms and 20 per cent of various stages in the evolutionary cycle of these forms. We have not been able, so far, to get rid of these intermediate forms; nevertheless, we do not think that this would affect seriously the relative value of our results.

The comparative estimation of nitrogen and phosphorus shows that the nitrogen content is higher in the normal *Proteus* than in the *L*-forms, while the phosphorus content, on the contrary, is lower.

Treatment of the *L*-forms with cold 5 per cent trichloroacetic acid gives an acid-soluble fraction, the total nitrogen of which represents about 6 per cent of the total nitrogen of the micro elements, and the phosphorus 55 per cent of the total phosphorus; under the same conditions, the normal *Proteus* loses about 8·5 per cent of its total nitrogen, but only 22 per cent of its phosphorus. This demonstrates in the *L*-forms an accumulation of small molecules of phosphorus compounds.

Treatment with boiling alcohol for 1 hr. and with boiling ether for 30 min. allows the extraction of

COMPARATIVE ANALYSIS OF NORMAL *Proteus* AND OF THEIR *L*-FORMS (per 100 parts dry weight)

| | Total N | Total P | $\frac{N}{P}$ | Total lipids | Total proteins | Total nucleic acid | DNA | RNA | $\frac{RNA}{DNA}$ |
|---|---|---|---|---|---|---|---|---|---|
| Normal *Proteus* | 14·77 | 2·45 | 0·60 | 6·0 | 73·0 | 11·59 | 3·28 | 8·31 | 2·50 |
| *L*-forms | 10·27 | 2·88 | 0·36 | 24·3 | 58·9 | 1 65 | 1·45 | 0·20 | 0·14 |

24·3 mgm. lipids per 100 mgm. of dry weight. The quantitative importance of this lipidic fraction should be noted. It is much more important than that which can be extracted from normal *Proteus* (for example, 4–8 per cent). The lipidic fraction contains 2·16 per cent phosphorus.

Analysis of the nucleic acids[3] in the *L*-forms free from lipids and the acid-soluble fraction shows clearly an amount of deoxyribonucleic acid (1·45 per cent of the dry weight of the initial material) greater than that of ribonucleic acid (0·20 per cent). The ratio of ribonucleic to deoxyribonucleic acid is thus, for the *L*-forms, just the reverse of that found in normal bacteria. The amount of ribonucleic acid in ordinary bacteria, even in the lag phase (that is, at the time when ribonucleic acid is at its lowest), is generally equal to, or greater than, the amount of deoxyribonucleic acid.

A summary of our results is given in the accompanying table.

## Contamination of Nectar with the Systemic Insecticide 'Schradan'

RIPPER *et al.*[1] have shown that the organophosphorus insecticide, octamethylpyrophosphoramide ('Schradan'), when sprayed on leaves, is absorbed and translocated to other parts of the plant. Metcalf and March[2] have demonstrated the tolerance to 'Schradan' shown by the honey bee. Using radioactive 'Schradan', containing phosphorus-32, we have examined the possibility of the unchanged insecticide being present in the nectar of flowers and afterwards appearing in honey.

The leaves of white mustard plants (*Sinapis alba*) were sprayed during July 1952 with an aqueous solution of radioactive 'Schradan' (about 0·75 μC. per ml.) also containing radioinactive 'Schradan' (0·16 per cent) and a wetter. A total of 4 ml. per plant was applied in five applications over five days. The plants when treated were approximately 1 ft. in height and had doubled their size by the end of the experiment (five weeks). All flowers open on the last day of spraying and on the following day were removed, to obviate the possibility of direct contamination of nectar by the spray. Flowers that opened three to twelve days after the completion of the spraying were used as the source of a bulk sample of nectar for assessment of 'Schradan' content. After chloroform fractionation, as recommended by Ripper *et al.*[1], radio-assay indicated a concentration of 5·5 p.p.m. of unchanged 'Schradan' in the nectar. Nectar collected over later periods showed lower contents of the unchanged insecticide.

Another test made with borage (*Borago officinalis*) confirmed that unchanged 'Schradan' could occur in nectar. In this plant the comparable value was 2·5 p.p.m.

Other work has shown that 'Schradan' is not decomposed while in the honey stomach of the bee or in honey during a storage period of ten weeks.

Full details of this work are being published elsewhere.

## Transmission of Hop Mosaic by *Phorodon humuli* (Schrank)

MOSAIC disease of hops was first described by Salmon[1]. Later Thrupp[2], and Salmon and Ware[3], showed it to be transmissible by grafting. This was followed by the extensive studies of Mackenzie *et al.*[4], who showed that some commercial varieties were symptomless carriers. Growers' observations of spread from carrier varieties to adjacent susceptible hops were confirmed by Keyworth[5].

It was suspected that insects were responsible for the spread of mosaic, and in 1948 an extensive experiment was carried out to test the ability of the hop–damson aphid, *Phorodon humuli* (Schrank), to transmit the virus. Eggs of this aphid, laid on *Prunus* spp. in the autumn, hatch in early spring and, after several wingless generations, winged forms develop which migrate to hop. There follows a succession of asexual wingless generations throughout the summer. Another winged generation occurs which returns to *Prunus* and produces wingless sexual females. These are fertilized by winged males which develop to maturity on hops and then migrate to *Prunus*. 3,520 summer wingless *P. humuli* were tested as vectors with short and long feeding periods, using eight different sources of hop mosaic as infectors, but there was no transmission to the 128 indicator plants.

Work was therefore started to find other insects that might be suspected of transmitting hop mosaic. A survey of the insects occurring on hops was made by Paine[6], and an experiment designed to determine the period during which mosaic spreads. Monthly collections of insects were made at five gardens in which mosaic was known to be spreading. Thirty-five species were recorded in one year and twenty-three in the next; only six species were found in both years. As mosaic had spread in both years it was inferred that one or more of these six species might have been involved in its transmission.

All the insects that had been collected in one hour from a hundred plants each month were allowed to feed on mosaic-infected hops and then transferred to ninety test hop plants (Bramlings), each of which received one or more species. Four of these plants developed mosaic within one year; and the only species which all four had received was the spring winged form of *P. humuli*.

To find out the period during which mosaic spreads, ten plants of a susceptible variety (Petham Golding) were placed in a garden of a carrier variety (Brewers Gold) each month from March to August. Each batch of these indicator hop plants was stored at 0° C. and then grown for one month in an insect-proof glasshouse; the potted plants were then exposed in the field of infected hops for one month and then returned to the glasshouse for observation. Two of the plants exposed in June and one exposed in July later developed mosaic.

The facts—(1) that the spring winged form of *P. humuli* had occurred in both years collections; (2) that four plants developed mosaic after treatment with this form of the aphid; (3) the spread of this disease had occurred during the later period of the spring winged generation flight—suggested that this aphid should be retested as a vector of mosaic, using the spring winged generation.

In 1951 Petham Golding hops were infested with winged *P. humuli* collected from hedgerow *Prunus* species. Each of the ten test plants received some aphids direct from the *Prunus* and others which were first fed on mosaic-infected hops for 1 hr.–30 days. Nine of the ten test plants developed a line-pattern symptom later in the same year, and early in 1952 six of these test plants developed vein banding and downward leaf curling for a short period and then apparently recovered. Since then, four of the test plants have developed mosaic symptoms, including the plant that did not show line pattern in 1951. No symptoms have developed on any of the controls.

No other case is known where one form of an aphid is able to transmit a virus while another form of the same species is not, and further investigations are being made to elucidate this phenomenon. Work is also being continued to determine the relationship between viruses occurring in *Prunus* species and those found in the hop.

## Spermatogenesis in *Lumbricus terrestris* L., Müll.

While the histology of spermatogenesis *s.str.*, that is, the maturation of the spermatids to form ripe spermatozoa in *Lumbricus terrestris* L., is known in detail, explanations of the orientation of the developing spermatid remain somewhat obscure. The only complete and easily available information is contained in the general text-book of Borradaile[1], where diagrams show the 'tail' of the sperm arising at the cytoplasmic vesicle at the periphery of the morula and remaining in this position during its subsequent elongation away from the cytophore. The cytoplasmic vesicle and the cytophore are shown in Fig. 1 (*c.v.*, *cph.*). The account of Hesse[2] interprets the orientation of the spermatid in the same way as Borradaile, stating that the acrosome or 'head' end arises from the cytoplasmic pedicle which is directed towards the centre of the morula (Fig. 1, *c.p.*). Depdolla[3], however, explains the orientation in the reverse way and regards the cytoplasmic vesicle as representing the acrosome or 'head' end of the sperm, and states that the 'tail' develops from the cytoplasmic pedicle. More recent work by Chatton and Tuzet[4], who made a very detailed histological examination, confirms this view, though no figures are given in their work of the final relationship of the ripe spermatozoa to the cytophore.

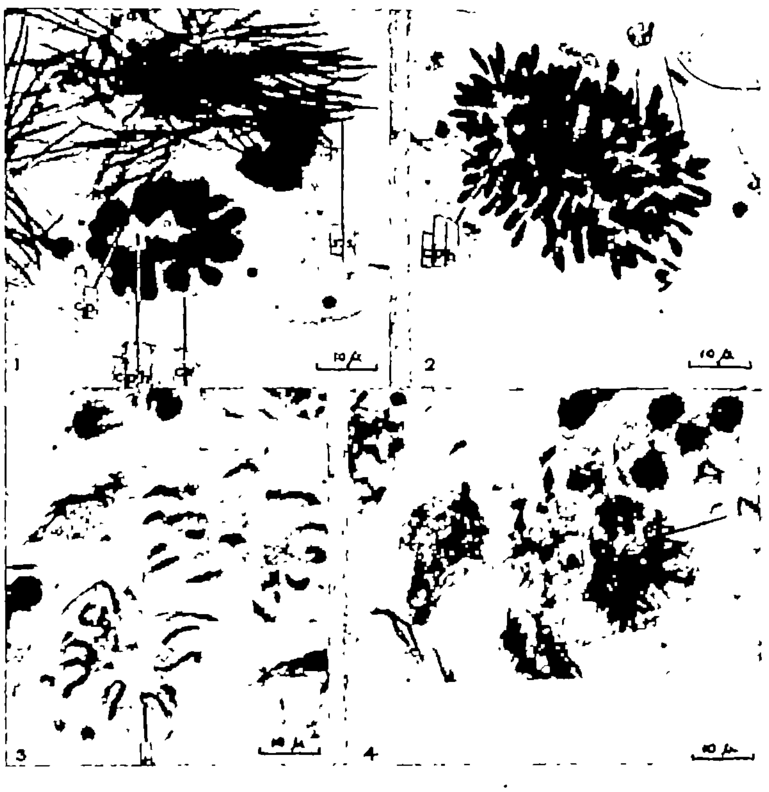

Fig. 1. Early stage in spermatogenesis of *Lumbricus terrestris*

Fig. 2. Later stage in spermatogenesis of *Lumbricus terrestris*

Figs. 3 and 4. Successive stages in spermatogenesis of *Fasciola hepatica*, showing origin of 'tail' region next the cytophore

*c.p.*, Cytoplasmic pedicle; *cph.*, cytophore; *c.v.*, cytoplasmic vesicle; *r.s.*, ripe sperm; *t*, tail

Fig. 2 shows the elongating nuclei of the spermatids, with the broad ends which were nearest the cytoplasmic vesicle towards the outside and the pointed ends directed inwards towards the cytophore (Fig. 2, *cph.*). If this orientation persists throughout maturation it follows, on the basis of the interpretation of Chatton and Tuzet, that the ripe spermatozoa of *Lumbricus* adhere to the cytophore by the tips of their 'tail' ends, which is the reverse of what the Borradaile diagram shows, and the reverse of that observed by me on living unstained material. Whitehouse and Grove[5] confirm the latter observation and state that in most stained smears only the 'head' of the sperm stains, and that is attached to the cytophore (Fig. 1, *r.s.*).

Accordingly, I suggest that there may be a reversal of orientation of the spermatid between the stage shown in Fig. 2 and the final stage. As a result of investigating spermatogenesis in the trematode, *Fasciola hepatica* L., and in the cestode, *Eubothrium crassum* (Bloch), it appears that there is some evidence to support this view (assuming the basic process to bear some similarity in the Platyhelminthes and Annelida). In both the Platyhelminthes there is, as in *Lumbricus*, a similar outpushing of the wide end of the elongating spermatid nucleus at the cytoplasmic vesicle, while the inwardly directed, pointed end of the nucleus coils and appears to form the 'tail' of the sperm, moving towards the periphery at the same time (Figs. 3 and 4, *t.*). Wilmott[6], working on the trematode *Gigantocotyle bathycotyle* Nasmark, figures a stage very similar to that observed by me, though she makes no comment upon orientation. Observation of this stage is made easier in the Platyhelminthes because, first, the development concerns only the nucleus—it is doubtful if any cytoplasm enters into the final composition of the ripe spermatozoa in this group—and, secondly, the cytophore is here formed sooner and is relatively more extensive, making the change in orientation more plainly visible and possibly causing the process to slow down. Unfortunately, in the Platyhelminthes the ripe spermatozoa do not adhere for long, if at all, to the cytophore, so that there is no stage visible which corresponds with the final stage in *Lumbricus terrestris*. However, it seems very possible that the mobility of the 'tail', together with its elongation, coiling and subsequent uncoiling, would cause the 'tail' to be thrown free of the cytophore before the 'head' end.

## Change in the Composition of the Bottom Fauna of the Dogger Bank Area

UNDER the above title, Erik Ursin[1] reports certain differences between the bottom fauna found by him during 1950–51, and its composition as reported by F. M. Davis[2] during 1921–23. I am able to confirm most of these differences, because part of my work took me to the same area, and at the same time, as Ursin. But I think that caution is needed in assuming that the differences are due to real changes in the bottom fauna. It will be remembered that Davis thought that the spatfalls of molluscs are likely to be local and uncertain, and his 'soil-current' theory is an enunciation of this belief. The substitution of *Ensis ensis* and *Tellina fabula*, during 1950–51, for *Spisula subtruncata* and *Mactra corallina* as the dominant lamellibranchs, lends support to Davis's theory. But Davis worked with a Petersen grab, and Ursin and I are both using van Veens, and since the latter is probably more efficient at digging in sand than the former[3], it is likely that these differences in fauna are at least partly the results of changed gear. There is much need for a thorough comparison of the two instruments.

It is also important to remember that the comparisons were made between an October cruise of 1921 and a spring survey during 1950–51, and that important spatfalls are likely to occur in the summer, which, if all the molluscs should disappear before spring of the following year, will not yield results similar to those of a spring survey. In fact, I have just (October 31–November 4) surveyed the west Dogger Bank again. I discovered the presence of many hundreds of 1–1·5 cm. *Mactra corallina* in a large patch, roughly twenty miles north-north-east of where Davis discovered the same species to predominate. I have always found enormous numbers of freshly coloured large (2–3 cm.) empty shells of *M. corallina* in this area; but the living ones had up to now escaped me, presumably because of the timing of the surveys. In November there were 2,775 *Mactra* per m.$^2$ at the greatest density.

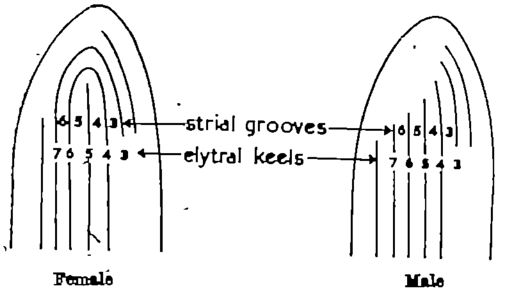
## A Simple Method for Sexing the Confused Flour Beetle

THE sub-basal pit, on the front femora of males of several species of *Tribolium*[1], is very difficult to observe in *T. confusum* Duv., and its use in sexing large numbers of the beetles is not practical.

I have now found that *T. confusum* can be much more conveniently sexed by examination of the elytral declivity, where the keels and strial grooves form a pattern characteristic of the sex (see accompanying diagram). In the female the keels on the seventh and third intervals are united distally, as are those on the sixth and fourth. The keels may be, in part, absent or reduced to slight ridges; but the sixth strial groove is always clearly distinguishable up to its junction with the third. In addition, the apical area of the elytron beyond the keels does not have a distended appearance and has punctures approximately the same size as those on the striæ. In the male the keels on the seventh and third intervals are never united distally, and the sixth strial groove is never continuous with the third. The apical area beyond the keels has a distended appearance and has punctures coarser than those on the striæ. Most individuals could be sexed with certainty by examination of one elytron, under a binocular microscope (× 15); but in a doubtful case the other elytron should be examined. In a test of the method more than two thousand beetles were correctly sexed. Dead desiccated beetles or anaesthetized living beetles



*Tribolium confusum* Duv. Dorso-lateral view of apical halves of right elytra of female and male

can be equally easily sexed, and with practice can be examined at the rate of 400–500 per hour.

*T. destructor* Uyttenb. can be readily sexed on similar elytral characters. Reliable results can also be obtained with *T. castaneum* Herbst; but the characters are much less obvious and considerable practice is necessary.

This note is published with the permission of the Department of Scientific and Industrial Research.

## Urea Complexes of Rape-oil Fatty Acids

In the course of investigations on the catalytic autoxidation of highly purified brassidic acid (*trans* docos-13-enoic acid), methods for the isolation of erucic acid, the *cis* isomer, have been examined.

The source of this acid has been the mixed fatty acids from the saponification of rape-oil which, in addition to about 50 per cent erucic acid, contain quantities of oleic acid and smaller amounts of linoleic and $C_{16}$–$C_{24}$ even-numbered saturated acids.

Schlenk and Holman[1] have prepared urea complexes of a number of higher saturated and unsaturated fatty acids by treatment with urea in methanol solution. These workers have shown that complex yields increase with molecular weight of the acid but decrease with unsaturation. The yields from linoleic acids were found to be zero under the conditions used. From the methyl esters of mixed olive-oil fatty acids, these workers isolated highly purified methyl oleate by a urea-complex methyl ester fractionation technique, and it appeared that a similar method could be applied to the mixed fatty acids of rape-oil.

In a preliminary experiment, 4 gm. of mixed fatty acids (iodine value 100) were treated with 15 gm. urea in 100 ml. methanol. On warming to dissolve and cooling, 14 gm. of needle-shaped crystals of the complex were deposited, which, on warming with water, yielded a white solid acid (iodine value, 68·3). It appeared that separation from unsaturated fatty acids had been effected, the solid acid consisting of erucic acid (iodine value, 75) and saturated fatty acids. A large-scale separation of the mixed fatty acids was then attempted by addition of urea in sufficient successive quantities to separate saturated acids, erucic acid, and lower monoethenoid and polyethenoid acids. 140 gm. mixed fatty acids yielded 94 gm. erucic acid concentrate (iodine value, 76·1; acid value, 171). Difficulty was experienced in completely removing saturated acids by this method, since urea-complex yields of erucic and saturated stearic, arachidic and behenic acids are similar, and a final purification of the acid was effected by a lead salting method.

Urea complex fractionation appears to be advantageous for a preliminary separation of mixed rape-oil fatty acids during the preparation of erucic acid. The complete one-stage elimination of polyethenoid acids from the product is achieved. According to Hilditch[2], this is essential when the purified acid is used for investigations into the mechanism of autoxidation of monoethenoid unsaturated fatty acids.

## Influence of Trypan Blue on the Number of Circulating Eosinophils in Rats

Gordon and Katsh[1] suggested that the adrenal cortex exerts a regulatory influence upon the function of the macrophagic system. Selye[2] observed an increase of the phagocytic activity of the reticulo-endothelial system in the alarm reaction.

In the present study, an attempt has been made to determine whether the eosinopenic response in stress is influenced by the functional state of the reticulo-endothelial system. It has been observed recently that the functional depression which follows the 'blocking' of the reticulo-endothelial system is of short duration[3]. In my experiments, 'blocking' was produced by repeated injections of trypan blue.

Young male white rats weighing about 100 gm. were used. Stress was produced by the subcutaneous administration of adrenaline (Upjohn) in doses of 0·05 mgm./100 gm. body-weight. Eosinophil counts were carried out by the method of Speirs and Meyer[4]. One group of rats received intraperitoneally, on two subsequent days, a solution of 1 per cent trypan blue in saline (dose, 1 ml./100 gm. body-weight). Another group received on the first day the same amount of an isotonic solution of sodium chloride, on the second day trypan blue. The third, control, group received the solution of sodium chloride on both days. Eosinophil counts were performed in all the groups 20 hr. after the second injection. Epinephrine was then administered and eosinophil counts repeated 3 hr. later. The results are summarized in the accompanying table.

It is obvious that the injection of trypan blue is followed by a significant ($P < 0.001$) increase of the number of circulating eosinophils, whereas the

EFFECT OF TRYPAN BLUE AND ADRENALINE ON THE NUMBER OF CIRCULATING EOSINOPHILS IN RATS

| No. of animals | Treatment | Eosinophils in 1 c.mm. | Fall in eosinophil count following adrenaline (% of initial value) |
|---|---|---|---|
| 35 | Sodium chloride | 290 ± 8·14* | 29·40 ± 8·47 |
| 24 | Sodium chloride + trypan blue | 432 ± 24·78 | 46·16 ± 5·68 |
| 12 | Trypan blue | 606 ± 73·05 | 70·50 ± 3·78 |

* Standard error of the mean.

response to adrenaline stress is not abolished. It seems, therefore, that although the 'block' produces an increase of circulating eosinophils, the functional state of the reticulo-endothelial system has no influence on the eosinopenic response observed in stress.

Detailed hæmatological and bone-marrow studies of rats treated with trypan blue will be published elsewhere.

## Extraction of Acetylcholine from Brain Tissue

In some recent attempts[1] to follow rapid changes in the concentration of acetylcholine in mammalian brain *in vivo*, the experimental animals were killed by freezing in liquid air, a method which had already yielded valuable results when applied to the study of certain other labile metabolites[2]. As an accompaniment to these studies, one of us[3] reported that the amount of acetylcholine which can be extracted from excised brain frozen in liquid air is some 13 per cent greater than when it is extracted from unfrozen tissue by the more usual methods. Since this work was completed, however, Elliott and his colleagues[4,5] have claimed that a complete extraction can be achieved only by homogenizing the unfrozen brain in an acid saline solution; according to these workers, previous freezing of the excised tissue results in a loss of up to 50 per cent of its contained acetylcholine. It has, however, proved impossible to confirm these findings, as the following experimental results testify.

Acetylcholine was extracted from the excised brains of adult rats, using the method described by Elliott *et al.*[4], except that the extracts were assayed in the frog rectus muscle. While histological examination showed that the homogenization had been efficiently carried out, the amount of acetylcholine extracted corresponded to a brain concentration of only 1·69 ± S.E. 0·12 µgm. per gm. (ten animals). A second series of brains was extracted by a similar method, using a bladed homogenizer (10,000 r.p.m.), and was found to contain 1·73 ± S.E. 0·03 µgm. acetylcholine per gm. (four animals). These figures are very much lower than those reported by Elliott and his co-workers, namely, 3·45 µgm. per gm., and are similar to those usually quoted for excised tissue. It seems possible that the leech muscle used by the Canadian workers was affected by sensitizing substances. MacIntosh[6] found that saline extracts of mouse brain do exert a sensitizing effect on the leech preparation, though Elliott and his colleagues[4] deny that their extracts had a similar effect. Tobias and his co-workers[7] used an extraction technique similar to that of Elliott *et al.* but assayed their preparations on the frog rectus muscle, which is known to be very susceptible to the effects of sensitizing substances in brain extracts. Though they failed to eliminate the effects of these agents and must therefore have obtained an exaggerated estimate of the amount of acetylcholine present in their extracts, their results are very similar to those quoted by Elliott *et al.* In the present experiments, it was found that, for saline extracts of brain, an acetylcholine assay of 1·8 µgm. per gm. rose to 2·9 µgm. per gm. (mean of six experiments) when the effect of the sensitizing substances was not controlled, though the rectus muscles were very sensitive and had been treated with optimal amounts of neostigmine.

In other experiments, excised brain tissue was divided into two equal portions, one of which was homogenized in acidified saline solution, while the other, after freezing in liquid air, was powdered and its acetylcholine extracted by contact with aqueous trichloroacetic acid for twenty minutes. The homogenized brain was found to contain 1·38 ± 0·03 µgm. acetylcholine per gm., the frozen brain 1·40 ± 0·11 µgm. per gm. (four experiments).

There is thus no evidence that freezing is associated with a loss of acetylcholine; it is possible that the results of Elliott and Henderson[5] were due to their allowing some thawing of their frozen tissue before its acetylcholinesterase had been completely inactivated, for acetylcholine disappears very rapidly from frozen tissue if even momentary thawing is allowed to occur[3].

Finally, the acetylcholine content of the brains of a series of sixteen adult rats, killed by immersion in liquid air, was found to be 2·52 ± 0·15 µgm./gm., while the excised brains of litter mates of five of these animals contained only 1·82 ± 0·02 µgm./gm. There seems to be no loss of acetylcholine from excised brain during the first few minutes after decapitation, and it would appear that the low content of acetylcholine in the excised brain resulted from the effects of the violent stimulation accompanying the process of decapitation. It is evident that such an effect could mask any but marked differences in the concentration of acetylcholine in the brains of animals subjected to different experimental procedures. For the detection of such differences, as well as for the determination of the absolute acetylcholine content of the brain, the use of liquid air would seem to remain the method of choice.

## Passive Transfer of Transplantation Immunity

Passive transfer of transplantation immunity has never been successfully achieved in a simple way. Previous demonstrations of passive transfer have either employed special techniques giving results which are difficult to interpret[1,2], or else the nature of the immunity has been in doubt[3]. Here is reported a simple procedure for passively transferring transplantation immunity to a tumour.

The tumour used was lymphosarcoma *6C3HED*, described by Gardner, Dougherty and Williams[4]. Mice of Strong's *CBA* line are uniformly susceptible to the tumour, and mice of Strong's *C57* line, and the *Ai* line inbred in this laboratory, are uniformly non-susceptible. The survival of grafts of the tumour in non-susceptible mice has been measured by allowing grafts of the tumour to lie in these mice, and then regrafting them into susceptible mice, where growth of the tumour indicates that the tumour had survived in the non-susceptible host. In this way the median survival time of the tumour in *Ai* mice was found to be 9·9 ± 0·8 days. If the *Ai* mice had been previously immunized by inoculation with the tumour, the median survival time was then 2·1 ± 0·3 days. In order to demonstrate passive transfer of transplantation immunity, tissues were transferred from immunized non-susceptible mice into non-susceptible mice from the same line, and the proportion of test grafts of the tumour which survived after eight days in these hosts was measured. Approximately 70 per cent of the grafts survived this time in untreated non-susceptible mice, and after successful transfer of immunity this proportion was reduced.

Subcutaneous inoculations of serum and peritoneal exudate from immune mice both proved ineffective in transferring immunity, in experiments with *Ai* mice. However, evidence was obtained for transfer of immunity by intraperitoneal transplantation of 'immune' lymph nodes, and further investigations of this method of transfer were carried out in *C57* mice. Lymph nodes from immune mice were found to be highly effective in transferring immunity.

This method of transfer could be shown to be genuinely passive, and not merely a transfer with the lymph nodes of tumour cells or possibly of isoantigenic particles. Immune lymph-node mince was inoculated into *CBA* mice, but invariably failed to give rise to tumours. Furthermore, the duration of the immunity was estimated by leaving intervals between inoculation of immune lymph nodes and test tumour grafts. The immunity appeared to remain firm for four days, weaken after ten days, and disappear after twenty days. Lymph nodes taken from non-susceptible mice ten days after inoculation with the tumour were effective in transferring immunity, but after twenty days this power was lost. At this time all the tumour cells had been killed, and the nodes, which after ten days hypertrophy to approximately double their normal weight, have almost returned to normal. Only local lymph nodes were effective in transferring immunity; the corresponding nodes from the opposite side to the site of tumour inoculation were not effective. Neither spleen nor muscle from immunized mice was found to be effective.

This investigation, which will be published elsewhere in detail, shows that transplantation immunity shares with immunity to simple organic compounds[5] and immunity to tuberculin[6] the property of being transferred with greater facility by cells than by serum.

I wish to thank Prof. P. B. Medawar and Dr. K. B. Roberts for much helpful advice and discussion.

## Hyaluronidase and Salicylates

It has been shown by Hechter[1] that, in the living animal, the spreading effect of hyaluronidase depends upon several factors. Inhibition of this effect such as has been reported to result from the administration of salicylates[2] may not therefore be due, necessarily, to depression of enzyme activity. The effect of hyaluronidase upon the permeability of connective tissue may be demonstrated on pieces of isolated fascia *in vitro*[3]. This method may be expected to give an indication of the action of hyaluronidase alone, since other factors which complicate the phenomenon of spread *in vivo* are excluded.

Three white stock mice, two male and one female, each weighing 25 ± 2 gm., were given 1 per cent sodium salicylate in their drinking water for 48 hr.; in addition, 0·5 ml. of 1 per cent sodium salicylate was injected intraperitoneally 24 hr. and again from between 1 and 6 hr. before the end of this period. The mice were then killed and fascia from each was immediately moistened with 1 per cent sodium salicylate, pH 6·1, and fixed as an occluding membrane to the end of a glass tube in the way previously described[3]. The membrane was immersed in the same solution, and more solution was passed through it at a pressure of 4 cm. water. After a few minutes the rate of flow was measured. A solution of Benger's 'Hyalase' in 1 per cent sodium salicylate was then perfused and after two minutes the rate of flow was measured again. Each mouse provided two membranes, one from each flank; but one membrane was damaged in dissection and not used. As a control, five membranes were obtained from three mice to which no salicylate had been given but which were similar in other respects. Rates of flow before and after perfusion of hyaluronidase were measured exactly as before, except that 0·85 per cent sodium chloride, pH 5·6, was substituted for salicylate. The results are shown in the accompanying table.

The table shows that the increase of flow produced by hyaluronidase is of the same order in both groups. In view of the very great increase in rate of flow brought about by the enzyme in the presence of salicylate and, moreover, through tissue from animals to which salicylate had been copiously administered, it is hard to believe that salicylates can have any

| | Experimental | | | | | Control | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 1 | 2 | 3 | 4 | 5 |
| Initial rate of flow (µl./sec.) | 0 47 | 1·05 | 0·36 | 0·44 | 0 47 | 0·7 | 1·17 | 1 7 | 1·3 | 0·85 |
| Rate of flow after hyaluronidase (µl./sec.) | 10 0 | 16·0 | 6·6 | 13·6 | 10 0 | 20·0 | 20 0 | 20·0 | 20·0 | 11·0 |
| Increase (×) | 21 | 15 | 18 | 31 | 21 | 29 | 17 | 12 | 15 | 13 |

significant inhibiting effect upon the action of hyaluronidase on connective tissue. The explanation of their inhibition of the spreading phenomenon *in vivo* is therefore probably referable to their influence upon some other of the several factors upon which this phenomenon depends.

## Position of Radical Attack during Oxidation of Long-Chain Paraffins

Much work has been done on the liquid-phase oxidation of hydrocarbons; but strangely enough very few experiments of a fundamental nature have included what would appear to be the simplest models, namely, straight-chain paraffins. Any suggestions made so far concerning the point of oxygen attack when there is no preferred tertiary or activated hydrogen atom have been largely speculative. Ivanov *et al.*[1] claim, on the basis of certain products isolated from the oxidation of *n*-heptane, that attack takes place predominantly at the 2-position. Asinger[2] found that in the chlorination of dodecane and cetane attack was equal on all methylene groups, and suggested that the same would hold for oxidation.

In our research on the mechanism of liquid-phase oxidation of paraffins, we have determined the proportion of attack on the different carbon atoms of *n*-decane.

Pure *n*-decane was autoxidized at 145° C. with oxygen until the hydroperoxide concentration had reached 2·5 per cent w/w. From previous work in these laboratories it was known that at this extent of oxidation more than 80 per cent of the decane oxidized retains its original carbon skeleton, the oxygen being present as hydroperoxy- and carbonyl-groups; of these functional groups, 80 per cent are present in mono-functional compounds, the isomer distribution of which indicates the points of attack.

The oxidate was first hydrogenated on palladium black to reduce the hydroperoxides to the corresponding alcohols. In one case the oxygenated compounds were then separated from the unchanged hydrocarbon by chromatography and treated with lithium aluminium hydride to reduce the ketones to alcohols, thus yielding a mixture (*A*) of the total isomers from which the diols had to be removed.

Samples of the same hydrogenated oxidate were also subjected to chromatography by two different operators to separate hydroperoxide-derived alcohols ($B_1$ and $B_2$) from ketones. The two ketone fractions, on reduction with $LiAlH_4$, yielded isomeric decanol mixtures ($C_1$ and $C_2$). During chromatography a partial resolution of the isomeric alcohols was noted.

The infra-red spectra of all five mixtures were recorded and the proportion of isomers determined by matching against standard mixtures of the pure decanols. In some cases, for example, $C_2$, traces of non-decanol material compromised accurate matching.

Mixture *A* should give the more accurate picture since fewer manipulations were involved in this case.

| Decanol isomer | Each isomer as percentage of total isomers in the fraction | | | | | Limits of accuracy of infra-red analyses |
|---|---|---|---|---|---|---|
| | Decanols from total oxidate | Decanols from peroxides | | Decanols from ketones | | |
| | *A* | $B_1$ | $B_2$ | $C_1$ | $C_2$ | |
| 1-ol | 3 | Detected | < 3 | Detected | Not detected | ± 2 |
| 2-ol | 31 | 28 | 29 | 25 | 23 | ± 3 |
| 3-ol | 25 | 28 | 28 | 22 | [35] | ± 3 |
| 4-ol | 22 | 22 | 17 | 25 | 22 | ± 5 |
| 5-ol | 19 | 22 | 23 | 28 | 22 | ± 3 |

The sum of *B* and *C* in the correct proportions is in reasonable agreement with *A*. Part of the ketones may have arisen from the hydroperoxide during hydrogenation; after allowing for this, and considering the limits of accuracy of analysis, we believe that the isomeric distribution of the ketones is substantially the same as that of the hydroperoxides.

By continuous counter-current extraction, decane monohydroperoxide of purity greater than 97 per cent was isolated from an *n*-decane oxidate prepared at 145° C. The isolated peroxide, which contained 20 per cent of the oxygen absorbed, was hydrogenated over Adams's catalyst and the product was an equimolar mixture of the four secondary decanol isomers with possibly a trace of decan-1-ol. No other products could be detected by infra-red spectroscopy.

Our results show that there is a small proportion of attack at the terminal methyl groups, but that the major attack is distributed almost equally on the methylene groups of the *n*-decane chain. Allowing for the limits of accuracy of the infra-red analysis, the preference for the methylene groups near the ends of the chain is only slight.

Our thanks are due to Messrs. Philpotts and Thain for the spectroscopic analyses. This work is part of a joint investigation by the Anglo-Iranian Oil Co., Ltd., and the Distillers Co., Ltd., into the liquid-phase oxidation of paraffins, and we thank our Directors for permission to publish it.

## A Rapid Method for the Extraction of Radioiodide from Urine

The extraction of radioiodide from urine is important in radioiodide therapy, since without it the large quantities of highly radioactive urine which accumulate must be stored until the activity decays sufficiently to allow disposal.

Purves has described[1] a method for removing iodide from boiled, acidified and filtered urine, by passing it through a filter bed of asbestos impregnated with silver chloride, the iodide being retained in the filter bed, from which it can be afterwards removed as iodic acid by treatment with a solution of chlorine in $0 \cdot 1\,N$ sulphuric acid. Our experience with this method has been that in practice it fails because filtration of urine is a slow process, and also the asbestos mat invariably becomes clogged before 100 ml. of urine have passed through. Swiftness and simplicity of operation and an absolute minimum of handling are essential when dealing with highly radioactive solutions, and these considerations led us to evolve the following method, which is a practical improvement on that of Purves.

Silver chloride prepared by precipitation from silver nitrate was washed carefully with distilled water containing 1 per cent of nitric acid to free it from soluble salts. After drying in the dark at 100–110° C., it was fused in a silica dish at 465° C. The melt was allowed to solidify into a cake, removed from the dish by breaking the latter, and grated down with a coarse rasp. Silver chloride so prepared is effective in removing iodide from solutions. Varieties of silver chloride globules and sponges were also made by pouring the melt into cold water, but none of them was effective.

A glass tube of internal diameter 1 cm. and length 25 cm., wrapped in black paper, was filled with granules of silver chloride sieved free of dust. The packing was maintained in position by a plug of glass wool at each end. The urine, contained in the bottles used for collection, is drawn through the column by means of a water pump and discharged into a 2-lit. reservoir from which, after checking that the radioactivity has been removed by the column, it is disposed of down the sink. The extracted radioiodide is found almost completely within the first 2 cm. of the column.

The *p*H of the urine is adjusted to 2·8 with nitric acid using brom-phenol blue as indicator. If this is done as soon as possible after collection, neither boiling nor filtration of the urine is necessary and the extraction of iodide may be postponed, if desired, for 24–72 hr. The rate of flow through the column is limited only by the necessity of avoiding disturbance of the packing and of preventing channelling by gas bubbles produced by reduced pressure. Flow-rates of 100 ml./min. or more may be easily maintained.

The silver chloride preparation appears to be very stable. We have treated as much as 8 litres at a time without reducing the efficiency of the column, and there seems no reason why this figure should not be exceeded. In practice, however, the accumulation of dangerous quantities of radioactivity renders it advisable to decontaminate the column periodically as outlined above. This process also regenerates the silver chloride. We have so far passed more than 30 litres through the column without noticing any falling-off in its performance, as is indicated in the accompanying table. The column was decontaminated following passage of the volumes marked with asterisks.

| Volume of urine treated (ml.) | Flow-rate (ml./min.) | Delay before treatment (hr.) | Radioiodide extracted (per cent) |
|---|---|---|---|
| 1,500* | 100 | 24 | 97·8 |
| 800* | 100 | 48 | 78·4 |
| 1,000* | 25 | 72 | 88·9 |
| 1,600* | 30 | 72 | 82·9 |
| 8,000 | 20 | 48 | 80·8 |
| 1,400 | 70 | 48 | 78·8 |
| 8,000 | 10 | 48 | 88·9 |
| 750* | 100 | 24 | 78·9 |
| 1,600* | 100 | 24 | 78·9 |
| 8,000* | 125 | 48 | 97·1 |

It will be seen that the percentage extraction is considerably lower in some cases than others. Recirculating such urine through the column to remove the unextracted fraction is ineffective. This cannot at present be entirely explained, but is at least partially due to the presence of a variable quantity of protein-bound iodine which occurs in radioiodide–therapy urine, and which the column does not extract. This fraction is insignificant during the early hours of treatment, when the urinary output of radioactivity is at its greatest; and the column is, in fact, at its most efficient with such urine. We consider, therefore, that notwithstanding this limitation, the technique is of value as a practical expedient.

## Spontaneous and Induced Mutation

In his book "Bacterial Physiology" (New York, 1951), Dr. J. Lederberg writes, on page 94: "Not all workers have accepted the duality of adaptation mechanisms. Hinshelwood (1946), for example, has disregarded the selection of spontaneous mutants as an element of bacterial adaptations, apparently in order to bolster the applicability of his system of chemical kinetics to problems of bacterial growth".

The reference is to my short book, "The Chemical Kinetics of the Bacterial Cell" (which is described in its own preface as an "essay" and is not a reference work in any event). Nevertheless, it contains one chapter entitled "Variants" (that is, mutants) and another entitled "Selection" (one section of which is entitled "Superposition of Adaptation and Selection"). On page 193, in connexion with spontaneous and induced changes, it is stated: "It should be emphasized at the outset that one has not necessarily to do here with two competing or mutually exclusive hypotheses. Both types of mechanism may in fact operate in nature". On page 202 it is stated: "From this point of view the question would no longer be: what is the mechanism of variation and adaptation, but, which of the various mechanisms plays the more important part in any given example". On page 203 (in connexion with the same problem) it is stated: "Probably the correct interpretation varies from case to case". Ten pages later, still in the same connexion, it is stated: ". . . one is inclined to feel that a complete gradation of behaviour is probably to be detected, by the proper methods, among bacteria, just as it is known to exist in ordinary chemical reactions, where the relative importance of nucleation and growth of nuclei varies widely".

Experiments in this laboratory have led us to conclude that the induced adaptation mechanism operates in various particular cases. But we have never denied possible or even probable duality of mechanism in general.

C. N. Hinshelwood

Physical Chemistry Laboratory,
South Parks Road,
Oxford.

# FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

## Monday, February 9

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. G. Kreisel: "On Formalization".

Pharmaceutical Society (at 17 Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Prof. Gösta Edman: "Ash Pictures in the Identification and Assay of Vegetable Drugs".

Manchester Literary and Philosophical Society (at the University, Manchester)—Prof. W. A. Deer: "Trends in Petrology" (Percival Lecture).

## Tuesday, February 10

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. A. J. Arkell: "Toilet in Ancient Egypt".*

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers

British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Dr. Honor B. Fell, F.R.S.: "Organ Culture in Biological and Medical Research" ("The Scientific Basis of Medicine", 11).*

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. S. R. Tailby and Mr. Muhammed Aly Saleh: "Heat Transfer from Luminous Gas Flames in Vertical Tubes".

Institution of Mechanical Engineers, Automobile Division (joint meeting with the Institution of Electrical Engineers, at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. A. H. Ball and Mr. W. Nethercot: "Ignition Interference with Television Reception"

## Wednesday, February 11

Royal Sanitary Institute (at 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Dr. E. A. Parkin: "Problems of Insect Control in Large Kitchens".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. W. A. Stewart: "Increasing Beef Production"; Mr. W. R. Trehane: "Increasing Milk Production".

University of London (at the London Hospital Medical College, Turner Street, London, E.1), at 5 p.m.—Prof. A. Giroud (Paris): "Factors of Abnormal Development".*

University of London (at Bedford College, Regent's Park, London, N.W.1), at 5.15 p.m.—Mr. Eric Shipton: "The Recent Everest Expedition" ("Recent Exploration and Discovery", 2).*

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. F. C. Williams, F.R.S., and Mr. G. B. B. Chaplin: "A Method of Designing Transistor Trigger Circuits".

British Institution of Radio Engineers, London Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6.30 p.m.—Mr. L. A. Thomas: "Modern Trends in Communications Materials".

Society of Chemical Industry, Food Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. N. J. Berridge: "The Antibiotic Nisin and its use in the making and processing of Cheese"; Dr. Marie E. Coates: "The Mode of Action of Antibiotics in Animal Nutrition".

## Thursday, February 12

Royal Society (at Burlington House, Piccadilly, London W.1), at 4.30 p.m.—Dr. W. J. Pugh, F.R.S.: "The Research Work of the Geological Survey".

British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Prof. P. C. C. Garnham: "The Life Cycle of the Malaria Parasite" ("The Scientific Basis of Medicine", 12).*

Institution of the Rubber Industry (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. G. Lynch: "Practical Safety in the Rubber Industry"; at 7 p.m.—Dr. C. M. Blow: "Recent Developments in Chemical Derivatives of Rubber".

University of London (at King's College of Household and Social Science, Campden Hill Road, London, W.8), at 5.30 p.m.—Mr. Eric Shipton: "Mount Everest".* (Admission by ticket obtainable from the Secretary of the College.)

Birkbeck College (in the Assembly Hall, Institute of Education, Malet Street, London, W.C.1), at 6 p.m.—Prof. E. G. R. Taylor and Dr. Derek Price: A Discussion on the new Chaucer MS., "The Equatorie of the Planetis".*

## Friday, February 13

Institution of Mechanical Engineers (joint meeting with the Hydraulics Group, at Storey's Gate, St. James's Park, London, S.W.1), at 10.30 a.m.—Conference on "Hydraulic Servo-mechanisms".

Operational Research Club (joint meeting with the Ergonomics Research Society, in the Large Lecture Room, Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Discussion on "Men and Machines in Transport Systems".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Anniversary Meeting, followed by Annual General Meeting.

North-East Coast Institution of Engineers and Shipbuilders (at the Mining Institute, Neville Hall, Newcastle-upon-Tyne), at 6.15 p.m.—Mr. J. D. Hislop: "The Role of Non-Destructive Testing in Industry".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. J. W. Mitchell: "Some Experiments on Photographic Sensitivity".

## Saturday, February 14

Bradford Chemical Society (at the Technical College, Bradford), at 2 p.m.—Research Colloquium.*

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. R. D. Barnett: "Cyrene, a Greek City in North Africa".*

---

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Deputy Coal Survey Officer (with a good honours degree, or equivalent, in chemistry, fuel technology, or geology, preferably with industrial experience and experience in laboratory control) at the Coal Survey Laboratory, Nottingham—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, endorsed TT/584 (February 14).

First Grade Engineering Assistant (sewerage) in the City Engineer's Department, Port Elizabeth—Davis and Soper, Ltd., Agents to the City Council of Port Elizabeth, 52–54 St. Mary Axe, London, E.C.3 (February 14).

Graduate Assistant Science Mistress at the Lady Edridge Grammar School, South Norwood, to teach Physics throughout the school to advanced level of the G.C.E.—The Chief Education Officer, Education Office, Katharine Street, Croydon, Surrey (February 14).

Scientific Officer for research and development work on electronic instrumentation for use in trials of guided missiles (Ref. A.7/53A), an Experimental Officer for development and modification of electronic instrumentation used for trials of guided missiles and to supervise the field operation and maintenance of this class of equipment (Ref. A.8/53A), and an Assistant Experimental Officer to assist in development, operation, maintenance, calibration, etc., of telemetry equipment (Ref. A.9/53A), at Ministry of Supply Establishment at Aberporth, South Wales—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No. (February 14)

Scientific Technical Officer (Grade II or III) at the Central Laboratory, Shade House, Bolton Road, Pendlebury, interested in the investigational side of coal sampling and preparation—The Divisional Establishment Officer, National Coal Board, North-Western Division, 40 Portland Street, Manchester 1 (February 14).

Scientific Technical Officer (Grade II or III) (with a scientific background mainly in chemistry, and able to abstract and translate) as Technical Librarian at the Central Laboratory, Shade House, Bolton Road, Pendlebury—The Divisional Establishment Officer, National Coal Board, North-Western Division, 40 Portland Street, Manchester 1 (February 14).

Speech Therapist to the Wallington Clinic—The County Medical Officer, County Hall, Kingston-upon-Thames, Surrey (February 14).

Research Assistant (good honours degree in engineering or science, or its equivalent with a knowledge of aerodynamics and training and aptitude for experimental work essential) in the Department of Aerodynamics, to assist in experimental research—The Registrar, College of Aeronautics, Cranfield, Bletchley, Bucks (February 16).

Assistant Lecturer in Geography—The Secretary, London School of Economics and Political Science, Houghton Street, Aldwych, London, W.C.2 (February 20).

Director of Studies and Lecturer (or Assistant Lecturer) in Geography—The Secretary, Girton College, Cambridge (February 20).

Control and Switchgear Engineer in the Mechanical and Electrical Engineering Branch at London headquarters—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/589 (February 21).

Geneticist for Poultry Research Centre, Edinburgh—The Secretary, Agricultural Research Council, 15 Regent Street, London, S.W.1 (February 21).

Research Chemist in the Soils and Plant Nutrition Section at Long Ashton Research Station—The Registrar and Secretary, The University, Bristol (February 21).

Chair of Physics applied to Medicine at Guy's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 25).

University Demonstrator in Agriculture (with a degree or postgraduate diploma in agriculture and, preferably, trained in field experimentation)—The Secretary, School of Agriculture, Cambridge (February 25).

Demonstrator and Research Assistant in Dental and Oral Pathology—The Registrar, The University, Sheffield (February 28).

I.C.I. Research Fellowships in Biochemistry, Chemistry, Engineering, Pharmacology, or Physics—The Secretary of University Court, The University, Glasgow (February 28).

Lecturer in Mathematics—The Secretary of University Court, The University, Glasgow (February 28)

Scientific Officer (with a good honours degree in mathematics and, preferably, specialized in mathematical statistics or analysis) to assist with mathematical problems arising from research on animal and plant populations—The Establishment Officer (S), Nature Conservancy, 91 Victoria Street, London, S.W.1 (February 28).

Structural Engineers in Government Departments—The Secretary, Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No. S.64–65/53 (February 28).

NUFFIELD FELLOWSHIPS AND SCHOLARSHIPS IN DENTISTRY—The Secretary, Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N.W.1 (Fellowships, March 1; Scholarships, June 30).

LECTURER IN MEDICAL PHYSICS (graduate in physics with research experience and interested in medical problems)—The Registrar, The University, Manchester 13 (March 2).

ROBERT BLAIR FELLOWSHIP for advanced study or research in applied science and technology abroad—The Education Officer, (EO/H1/2), London County Council, County Hall, London, S.E.1 (March 2).

REGIUS CHAIR OF FORENSIC MEDICINE in the University of Edinburgh—The Private Secretary, St. Andrew's House, Edinburgh (March 15).

LECTURER IN PHILOSOPHY—The Dean of Arts and Science, University of Alberta, Edmonton, Alberta, Canada (March 31).

LECTURER IN VETERINARY BIOCHEMISTRY, and an ASSISTANT LECTURER or LECTURER IN VETERINARY MEDICINE (farm animals)—The Registrar, The University, Liverpool (March 31).

PUPILS and PROBATIONERS IN CIVIL ENGINEERING, and PUPILS IN MECHANICAL AND ELECTRICAL ENGINEERING (including telecommunications), in the Colonial Engineering Service, mainly in West, East and Central Africa, Malaya and the Far East—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE/100/011 (March 31).

BIOLOGICAL SCHOLARSHIPS AND BURSARIES—The Secretary, Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N.W.1 (April 1).

I.C.I. RESEARCH FELLOWSHIPS IN BACTERIOLOGY, BIOCHEMISTRY, BIOMOLECULAR STRUCTURE, BOTANY (plant biochemistry), CHEMICAL ENGINEERING, CHEMISTRY, CHEMISTRY OF LEATHER MANUFACTURE, CHEMOTHERAPY, COLOUR CHEMISTRY AND DYEING, ENGINEERING (civil, electrical or mechanical), FUEL AND REFRACTORIES, GEOLOGY (including geochemistry), METALLURGY, MINING (selective flotation and geophysical surveying), PHARMACOLOGY, PHYSICS, PHYSIOLOGY, or TEXTILE INDUSTRIES (protein chemistry)—The Registrar, The University, Leeds 2 (April 20).

I.C.I. FELLOWSHIPS FOR RESEARCH IN CHEMISTRY, PHYSICS and allied subjects—The Registrar, The University, Manchester 13 (April 30).

I.C.I. FELLOWSHIPS FOR RESEARCH IN PHYSICS, CHEMISTRY, BIOCHEMISTRY, ENGINEERING, METALLURGY, PHARMACOLOGY, CHEMOTHERAPY, or related subjects—The Secretary of the Board of Research Studies, The Old Schools, Cambridge (April 30).

I.C.I. RESEARCH FELLOWSHIPS IN BIOCHEMISTRY, CHEMISTRY, CHEMOTHERAPY, ENGINEERING, METALLURGY, PHARMACOLOGY, PHYSICS or allied subjects—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

MR. AND MRS. JOHN JAFFE DONATION for a studentship in original scientific research—The Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1 (April 30).

SOCIOLOGICAL SCHOLARSHIPS AND BURSARIES—The Secretary, Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N.W.1 (May 1).

CIVIL ENGINEERS in Government Departments—The Secretary, Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No. S.64–66/53 (June 30).

ASSISTANT PHYSICIST—The Secretary, Board of Management for Glasgow Western Hospitals, 10 Park Circus, Glasgow, C.3.

BOTANIST (Plant Breeder) at Rokupr Rice Research Station, Sierra Leone—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27069/317.

CHIEF RESEARCH AND DEVELOPMENT OFFICER (with an honours degree in mining or science, and research and practical mining experience), Mines Department, Federation of Malaya—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.99/60/03.

CROP ECOLOGIST in the Department of Soil and Land Use Survey, Gold Coast, to collect yield data for various crops grown on different soils—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.79/13/03.

ELECTRICAL ENGINEERS and PHYSICISTS at the Ministry of Supply Telecommunications Research Establishment, Malvern: SCIENTIFIC OFFICER grade (Ref. A.5/53A) and EXPERIMENTAL and ASSISTANT EXPERIMENTAL OFFICER grades (Ref. A.6/53A) for research and development work on radio and electronic equipment in the Radar, Physics and Engineering Departments—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

ENGINEER (honours degree in mechanical engineering preferred) for research on new drives and designs for textile machines—The Wool Industries Research Association, Torridon, Headingley, Leeds 6.

EXECUTIVE ENGINEER in the Public Works Department, Uganda, to be responsible for construction and maintenance of roads, housing schemes, water supply, drainage, sewerage, and buildings—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.112/9/02.

EXPERIMENTAL OFFICER IN THE MECHANICAL ENGINEERING RESEARCH LABORATORY of the Department of Scientific and Industrial Research, East Kilbride, Glasgow, for research on plastic deformation of metals occurring in commercial processes, for example, rolling, drawing and forging—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.153/52A.

EXPERIMENTAL OFFICERS (with a pass degree in geology, mining, engineering or physics) for field work in Uganda, including supervision of examination of mineral deposits by pitting, trenching, shallow drilling and sampling; also some surveying and laying out of prospecting areas and collation of records—The London Director, Uganda Development Corporation, Ltd., 27 Regent Street, London, S.W.1.

EXPERIMENTAL OFFICERS IN THE RADIO DIVISION, Royal Aircraft Establishment, Farnborough, on development of electronic equipment, for radio frequency measurements, especially at centimetric wave-lengths, and for other detailed technical investigations—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.1/53A.

EXPERIMENTAL OFFICERS or ASSISTANT EXPERIMENTAL OFFICERS at the National Physical Laboratory, Teddington, for experimental work in the Ship Division—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.14/53A.

GEOLOGISTS (with a university degree in geology with first- or good second-class honours) in the Colonial Geological Survey Service—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.104/04.

LECTURER (with a good honours degree with some teaching or industrial experience, and preferably with a special interest in electronics or electroacoustics) IN THE PHYSICS DEPARTMENT—The Principal, Northampton Polytechnic, St. John Street, London, E.C.1.

METEOROLOGICAL OFFICER (with a first- or second-class honours degree in mathematics or physics, preferably with experience as a meteorologist) in Nyasaland—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.96/4/01.

METEOROLOGISTS in the British Caribbean Meteorological Service—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.57/26/01.

ORGANIC CHEMIST (Ph.D. preferred) in the Chemical Research Laboratory, Rheumatism Research Unit, to work with a team in the steroid field—W. Stansfield, Lyndhurst, Nether Edge Hospital, Sheffield 11.

PETROLOGIST (with an honours degree in geology with a specialist qualification in petrology, and one year's postgraduate study or experience) in the Gold Coast, for petrological investigations in field and laboratory, with chemical analysis of rocks and minerals—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.105/13/02.

PHYSICIST (with a good honours degree; an interest in statistical methods is desirable) for work concerned initially with the processing of textile fibres both from a practical and theoretical point of view—The Secretary, British Jute Trade Research Association, Kinnoull Road, Kingsway West, Dundee.

PHYSICIST (with a first- or second-class honours degree or equivalent in physics, and interested mainly in electromagnetic theory) in a Ministry of Supply establishment at Malvern, as theoretician on problems connected with design of high energy accelerators, with personal charge of a full-time computer—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.23/53A.

PHYSICISTS or ENGINEERS at the Royal Aircraft Establishment, Farnborough, to work on problems connected with either generation and distribution of electric power in aircraft, or on problems of electro-technology arising in design and development of aeronautical equipment (Ref. D.6/53A); ENGINEER with extensive electronic or electrical experience for development work on the application of electronic and electrical equipment to flight vibration testing of aircraft (Ref. D.7/53A)—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No

PHYSICS GRADUATE for research in the strength of paper and board—The Printing, Packaging and Allied Trades Research Association, Randalls Road, Leatherhead, Surrey.

POSTGRADUATE STUDENTSHIP IN PLANT BREEDING, ENTOMOLOGY AND PLANT PATHOLOGY—The Secretary, Empire Cotton Growing Corporation, 12 Chantrey House, Eccleston Street, London, S.W.1

PROFESSIONAL ENGINEERS in various Government Departments, in a wide variety of engineering duties—The Secretary, Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No. S.86/53.

SCIENCE or ENGINEERING GRADUATES for research in the CHEMICAL ENGINEERING DEPARTMENT on some aspects of flow of liquids through porous materials—The Registrar, Imperial College of Science and Technology, South Kensington, London, S.W.7.

SENIOR LECTURER IN CHARGE OF THE ELECTRONICS WORK OF THE DEPARTMENT OF ELECTRICAL ENGINEERING—The Secretary, Royal Technical College, George Street, Glasgow.

SENIOR SCIENTIFIC OFFICERS at Capenhurst, Chester, for analytical and vacuum technique development and work involving mass transfer in polyphase systems—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting Ref. 410.

SENIOR TECHNICAL OFFICER (with a degree in horticulture or botany or equivalent qualification, with suitable practical experience in postgraduate training in research) for Seed Production of Vegetable and Root Crops—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

SURVEYORS in the Gold Coast Local Civil Service for geodetic, topographical and cadastral surveys and the supervision of junior staff—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting DE.103/13/01.

# AUTONOMY OF UNIVERSITIES IN GREAT BRITAIN

THREE memoranda, dealing with the universities and government in Great Britain, with the University Grants Committee, and with Government grants-in-aid to universities in Great Britain, respectively, have been submitted to the Commission on Financing Higher Education, a private agency sponsored by the Association of American Universities. These memoranda have now been published*, with a foreword by J. D. Millett, the executive director of the Commission. The broad conclusion reached is that the British system is unlikely to be suitable for American conditions. On the Federal level, as Prof. Lindsay Rogers points out, the United States is so large and the number of institutions is so great that a single university grants committee would confront an impossible task. Apart from this, both Prof. Rogers and President Dodds are doubtful whether either the Washington atmosphere or local public opinion would be as favourable to the freedom and independence of the universities as both that of Whitehall and public opinion in general are in Great Britain. The risks of State interference are greater in the United States, primarily because of the financial control of the universities and colleges by boards of trustees which are not predominantly academic, and which may be less resistant to external pressure than academic staff would be.

Nevertheless, if this survey of the British system by three independent trained minds yields little by which the United States can profit directly, it is of real value for Great Britain. It is of the greater interest in that the surveys were made prior to the examination of the system conducted by the Select Committee on Estimates during February–March 1952. Its findings thus make an interesting counterpart to those of the Select Committee in its Fifth Report for the Session 1951–52 and also to Mr. H. B. Chubb's scholarly book, "The Control of Public Expenditure". Its importance lies principally in the independent analysis it provides of the conditions responsible for the past success of the system and the factors which may limit its functioning in future. It is accepted that the universities of the United Kingdom will continue to depend chiefly on the Government for financial support. All three authors agree that even with the greatest goodwill toward the universities and with the greatest respect for the tradition of academic freedom, the predominance of government financial support involves, at least indirectly, government guidance of academic policy. The system is one of compromise, the natural method by which toleration works. Toleration and compromise, as Sir Ernest Barker points out in his "Reflections on Government", are the basis of democratic government; and the continuance and the effectiveness of the University Grants Committee system depends accordingly on the continuance of that liberal tradition or spirit of accommodation.

---

* Government Assistance to Universities in Great Britain. Memoranda submitted to the Commission on Financing Higher Education by Harold W. Dodds, Louis M. Hacker and Lindsay Rogers. (Published for the Commission on Financing Higher Education.) Pp. xiii+133. (New York: Columbia University Press; London: Oxford University Press, 1952.) 16s. net.

The implications of this situation are well brought out in these memoranda, particularly in those of Prof. Rogers and President Dodds. The system works well in Great Britain because of social and political customs and institutions which are peculiar to the country and may even be peculiar to the institutions concerned; they are not reproduced or reproducible in the United States. Nor can it be assumed that they exist in other institutions for which the adoption of a like device has been suggested. In brief, the independence of the British universities cannot be secured by administrative devices alone. It will last just so long as public opinion is willing that the universities should be autonomous, and how long that will be depends on the good sense and moderation shown by the universities themselves.

The potentialities of conflict between government and universities are recognized, and the memoranda give frank expression to some of the fears and misgivings entertained by the universities. Equally there are comments they would do well to note; particularly, for example, the query whether the agreements reached in private between the University Grants Committee and individual universities in regard to non-recurrent grants take sufficient account of the interests of the whole community, or again whether the amount of such grants may not be influenced too much by the skill or experience of one university rather than another in negotiating or presenting its case. That such a position could arise, particularly in regard to the newer departments, has already been adduced as a reason for continuing earmarked grants in the social sciences until such departments are able to present their case on equal terms with older established departments.

The memoranda support the argument already advanced by the Select Committee on Estimates and accepted by the Treasury in a Memorandum on the Select Committee's report that more information should be supplied to Parliament regarding the spending of these large sums of money. The practical problem is to determine what information is to be supplied, in what form and when. So far as Parliament is concerned, there is the question of supplying this at a stage when control can be effective without infringing the autonomy of the universities, and here President Dodds is inclined to suggest that the principle of greater accountability to Parliament will ultimately prevail.

Whether, in fact, such accountability will infringe the independence of the universities depends, however, on the extent to which the value of academic autonomy is understood and appreciated by Parliament and by the community as a whole. There is an aspect of political education involved here to which the universities might well give more attention. The wider and freer assumption of their regional responsibilities, as urged by Prof. B. Dobrée and 'Bruce Truscot', for example, could help; but so could alumni associations of the type which so impressed the Anglo-American Council on Productivity's team on universities and industry. The recommendation in the report of the latter that the desirability of extending graduate contacts in this way should be explored by British universities may well be even more important, from the point of view of maintaining and extending public understanding and support of the universities, than from that of obtaining financial support from sources independent of the Government.

If the broad conclusion of these studies is accepted, that the success of the University Grants Committee rests fundamentally upon unwritten conventions and the personal and social relations of a homogeneous community of university men, in and out of government, sharing common tastes and a common outlook, the importance of a more strenuous effort to extend the area of public understanding both inside and outside Parliament is obvious. President Dodds is on less certain ground in his remarks as to the effect of developments in secondary education on the universities. His suggestion that the British universities are more specialized than American universities is a little surprising.

University autonomy may be less fortuitous, however, in Great Britain than President Dodds inclines to think; but there can be no doubt that the general climate of opinion is scarcely as favourable to an extension of the device as it was to the initiation and early development of the University Grants Committee. Some of the weaknesses of the existing system emphasized in these studies, notably the staffing of its secretariat, are already receiving attention in consequence of the report of the Select Committee on Estimates; but it is clear that full weight should be given to the factors here emphasized as essential to the working of the system before any detailed proposals are formulated for its extension to other bodies.

The existence of a great reservoir of goodwill in public opinion is perhaps the most important factor, and with the comments in these studies as to the supply of further information about the working of the universities and the expenditure of the Parliamentary grant, the universities, individually and through the University Grants Committee, can scarcely fail to give closer attention to this question of publicity. In fairness, however, it should be pointed out that newsprint is one factor which renders such publicity difficult: full accounts of the development and activities of particular universities in national or local newspapers are likely to reach a much wider public than the most attractive accounts which the University Grants Committee could issue officially.

Such reports could not, of course, replace the official accounts for the purpose of informed discussion in Parliament, for example; but they could assist the growth of public understanding, particularly if well supported by broadcast discussions or talks. For it is a main weakness of the proposals for extending the device which has proved so successful in dealing with the universities to other institutions that, by and large, the necessary public understanding of the situation does not exist. Paradoxically, of course, the existence of such public understanding would minimize or even eliminate the need for some of these proposals.

# CAN ECONOMICS BECOME AN EXACT SCIENCE?

Econometrics

By Prof. Gerhard Tintner. (A Wiley Publication in Economics.) Pp. xiii+370. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1952.) 46s. net.

A STUDENT of economics is told, early in his theoretical courses, that his subject is distinguished from the natural sciences by the fact that economic experiments are virtually impossible. The lecturer heaves a sigh of regret and passes on with evident satisfaction to a domain wherein economic concepts are defined and their consequences developed with exquisite acuteness and skill, untrammelled by the awkward necessity of comparing theory with fact except in the end-product.

This is one reason why economics has difficulty in obtaining recognition as a branch of science; but there are several others. Economists almost universally prefer a literary method of exposition, and even the most mathematically minded of them write down an equation in their main text with evident reluctance, preferring to relegate the mathematics to the decent obscurity of an appendix. This not only encourages a degree of prolixity which would not be tolerated in any natural science; it also enables them, by the use of phrases like 'other things being equal', 'in the long run' and 'marginal increments', to avoid writing down their boundary conditions or to count the relations between their variables, and hence to make only the vaguest intuitive approach to questions of the uniqueness and stability of their solutions.

Now it has to be admitted that major experiments in economics are indeed impossible and that mathematical economics has not yet succeeded in telling economists much that they did not already know. There is, nevertheless, a growing feeling that if real progress is to be made the literary method is insufficient. One sees many signs of dissatisfaction with the present state of theoretical economics among economists themselves, as well as among those natural scientists who are drawn into an interest in the subject. There has, for example, been a movement away from the rather indefinite and unmeasurable quantity 'utility' towards the observable 'indifference', and a further movement towards the measurement of consumers' preferences through experimental studies of family budgets. Attempts are being made to measure the flow of production factors around the economic system by studies of national accountancy. Experiments in micro-economics are now possible; and although macro-economics experiments remain a dim dream, the methods of statistics, which are particularly appropriate to situations involving a complex of causation, are increasingly being tried out. The economic air is full of model-building, studies of stochastic equations, problems of identifiability and the like, all of them requiring a mathematical technique for their formulation and a statistical technique for their verification; and at last it is being appreciated that dynamic movements are an essential part of even the elements of the subject and that many apparently static properties, such as stable equilibrium, must be studied in the light of velocities. accelerations or time-lags.

The stage seems to be set for the emergence of a quantitative science of economics. (Whether we call it econometrics or not is a matter of taste.) But the actors seem rather reluctant to appear, and when they do they are not very successful. One reason is that they try to do too much; another is that there are not enough of them with a training in natural science; and a third is that they are apt to trail off on abstract mathematical arguments without holding themselves firmly in sight of the main objective. One cannot altogether blame them. A man with a career to make and a reputation to establish has to publish something, and it is easier to obtain positive results in pure mathematics than in the detection of economic patterns among the very imperfect statistical material which exists to-day.

The purpose of this preamble is to put Prof. Gerhard Tintner's book in a correct setting. It is entitled "Econometrics"; but it is not a text-book of econometrics, simply because in the present state of knowledge there cannot be such a thing; by this I mean that there cannot be a smooth development of a theory of quantitative economics from a set of postulates leading to experimentally verifiable conclusions. What Prof. Tintner has done is bring together a great many of the attempts made by econometricians to quantify parts of their subject and to expound the statistical techniques which are required. The book is in three parts: Part 1 (79 pages) is a non-technical introduction to econometrics; Part 2 (107 pages) is an introduction to multivariate analysis; and Part 3 (146 pages) is entitled "Some Topics in Time-Series Analysis". The relative lengths of these parts are themselves an illustration of the greater emphasis placed on statistical techniques than on the development of a quantified economic theory.

The main substance of Part 1 is contained in the third chapter (there are four altogether) on "Some Illustrations of Econometric Research", in which Prof. Tintner exhibits the type of problem which has been tackled econometrically: for example, Schultz's work on demand and supply analysis, Dean's on cost functions, Douglas's on production functions, Waugh's on utility functions, Leontieff's development of the *tableau économique*, and various models by Haavelmo, Tinbergen and Klein. They are all gallant attempts, and it is unfair to scrutinize the work of pioneers with too critical an eye; but it has to be admitted that they are subject to very severe limitations.

Part 2 consists of three chapters, on multiple regression and correlation, on some applications thereof to multivariate analysis and on stochastic models with errors in the equations. Wherever possible, Prof. Tintner quotes examples of econometric applications, and the chapter on errors-in-equations will be a useful introduction to the abstract treatments which have so far appeared in book form.

Part 3 is a review of developments in the theory of stochastic time-series which has taken place during the past twenty years—trend, Fourier analysis, autocorrelation analysis, stochastic difference equations, correlogram analysis and variate differences. There is an appendix on the elements of matrices and determinants and numerical computation.

One of the most useful features of the book is that Prof. Tintner, who has a very extensive acquaintance with the literature of statistics and econometrics, has given full references to original sources, so that his book is a useful introduction for anyone who wants to take his studies deeper. Personally, I would have preferred to see those references assembled in an appendix and not given in footnotes. There are so many of them that at times a layer of text seems to float on a heavy substratum of reference, leading to that heckling of the text by footnotes against which protests have been lodged in other spheres. But the references are given, which is the main thing.

Prof. Tintner would, I am sure, be the first to acknowledge the shortcomings of this book, some of which are due to the imperfections of the subject and some to the difficulty of expressing advanced statistical methods in terms which economists can assimilate, and a few of which are his own responsibility. But all students of econometrics will want to read it, and it should do much to widen interest in a frustrating but extremely important field awaiting scientific exploration. M. G. Kendall

# PRINCIPLES OF QUANTUM THEORY

**Quantum Theory**

By David Bohm. (Prentice-Hall Physics Series.) Pp. ix+646. (New York: Prentice-Hall, Inc.; London: Constable and Co., Ltd., 1952.) 45s. net.

Dr. David Bohm has written a highly individual account of the non-relativistic quantum theory, his aim being to express the known results in terms of comparatively qualitative and imaginative concepts at an elementary level. The emphasis is mainly on the physical interpretation and logical structure of the theory, and the explanations given are unusually thorough. This is not to say that the mathematical development is neglected; the text contains neat derivations of most of the standard results. Altogether the book will be very valuable to the thoughtful student.

The first seven chapters develop the physical formulation of the quantum theory, which is built up rather inductively from the hypotheses of Planck and Einstein, the Bohr orbit theory and de Broglie's wave theory. This involves a careful discussion of the correspondence and uncertainty principles and of the changes produced by the process of observation. Dr. Bohm is successful in conveying the physical picture behind the quantum assumptions.

Chapter 8 is concerned with rather abstract matters. There are a discussion of the concepts of motion and of causes and an exposition of the difficult concept of complementarity. Dr. Bohm develops the interesting parallel between the uncertainties of quantum mechanics and the erratic nature of our thought processes; throughout the book are many biological analogies.

The second part of the book develops the mathematical formalism of wave functions, expectation values and probabilities, and the third part gives the usual solutions of standard problems. Proper importance is given to the classical limit, which is established by the W. K. B. approximation. There is a useful chapter on matrix methods, which are used effectively in various parts of the book, but the Dirac notation is not introduced. Three chapters are devoted to perturbation theory, both stationary and time-dependent. There is also an excellent chapter on scattering theory, which, in keeping with the rest of the book, contains an adequate discussion of the validity of the various approximation methods and of the equivalence of the time-dependent and stationary methods of solution. It is perhaps surprising, in a book of 640 pages, to find no account of relativistic electron theory or of second quantization; even the treatment of the symmetry properties of many-particle wave-functions is sketchy.

That the text is discursive may be judged from the fact that the theory of the hydrogen atom does not appear until p. 345. Wave mechanics is at best a queer business; some readers might be more willing to accept the concept that "the properties of matter are opposing potentialities which become precisely defined only at each other's expense and in interaction with an appropriate environment" if preceded, rather than followed, by the evidence that this point of view does at least lead to agreement with the very precise spectroscopic experiments.

The concluding chapters contain an account of the quantum theory of measurement and include a discussion of the famous paradox of Einstein, Rosen and Podolski which has played such an important part in clarifying our ideas on this subject. This leads on to Dr. Bohm's argument for the orthodox view, which he stresses in many earlier chapters, that the peculiarities of quantum mechanical behaviour cannot be attributed to the effects of hidden parameters acting classically. The argument gains greater interest as later papers show that Dr. Bohm now regards this view as open to question.

# ADVANCES IN PROTEIN CHEMISTRY

**Advances in Protein Chemistry**

Edited by M. L. Anson, Kenneth Bailey and John T. Edsall. Vol. 7. Pp. viii+411. (New York: Academic Press, Inc., 1952.) 8.50 dollars.

This latest volume of "Advances in Protein Chemistry" is a feast for the physical chemist, for five of the six articles deal with physical methods applicable to the study of proteins, or the results of such studies. This is inevitable, as three of the articles, comprising well over half the volume, deal with various aspects of the fibrous proteins (the structure of collagen fibrils; muscle contraction and fibrous muscle proteins; and the proteins of the mammalian epidermis), and these protein systems have been studied mainly by physical methods. Perhaps the volume is rather overweighted by these related topics.

The articles vary widely in their treatment and complexity. The review entitled "Infra-Red Analysis of the Structure of Amino-acids, Polypeptides, and Proteins", by G. B. B. M. Sutherland writing from Ann Arbor, should be compulsory reading for every honours student studying chemistry, biochemistry or physics; it gives an excellent survey of fundamental principles, methods, results and difficulties. On the other hand, the article on "Muscle Contraction and Fibrous Muscle Proteins" (H. H. Weber and H. Portzehl, of Tübingen) starts simply enough, "Muscle works by alternating between contraction and relaxation", and ends honestly, "Neither the study of the individual purified proteins of the myofibril, nor the brilliant investigations on the fine structure of the fibril, has led to any well-founded theory as to the nature and mechanism of the structural changes which take place in the contractile particles"; but most of the rest is for the expert only.

A splendid review on "The Arrangement of Amino-Acids in Proteins" is contributed by F. Sanger (Cambridge), who himself has devised and applied many of the methods he describes; the section on methods for the degradation of proteins and their inherent pitfalls is especially welcome. A discussion of nomenclature and symbolism for peptide chains and terminal residues is included. A new structure for vertebrate collagen fibrils, based on parallel, coiled, polypeptide chains (protofibrils) with transverse matching of corresponding chemical structures, is put forward by R. S. Bear (Massachusetts Institute of Technology). Work on the comparative structure and organization of mammalian epidermal cell proteins is discussed by K. M. Rudall (Leeds). Complementary to the article on infra-red spectroscopy, G. H. Beaven and E. R. Holiday (London Hospital) consider the "Ultraviolet Absorption Spectra of Proteins and Amino-Acids", especially the vibrational fine structures revealed by Holiday's 'moving-plate' spectrographic method, and the advantages and problems associated with analytical methods for proteins in terms of their aromatic amino-acid content.

It is a pleasure to see so many British authors featured in this volume—a welcome recognition of British contributions to protein chemistry. One suggestion may be made: the publishers should consider providing, in each subsequent volume, a cumulative list of titles in the whole series.

# DESCARTES: THE FATHER OF MODERNITY

## Descartes and the Modern Mind

By Prof. Albert G. A. Balz. Pp. xiv+492. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1952.) 63s. net.

MOST students of the seventeenth century will know the name of Prof. A. G. A. Balz. During the past twenty years, articles in learned reviews and a recent volume of essays, "Cartesian Studies", on the successors, both friendly and hostile, of Descartes have given us a foretaste of the scholarship and power of analysis which mark this distinguished volume, confessedly the fruit of many years of reflexion and study. Whether one agrees or disagrees with Prof. Balz's interpretation of Descartes, one cannot help being impressed by the sincerity and depth of his analysis, and it is refreshing to read a commentator who has meditated the texts of his philosopher and pondered them until he has wrought for himself and his reader a consistent meaning and interpretation. Prof. Balz does not close his eyes to the many difficulties and inconsistencies in the thought of Descartes, but the gaps he sees are not of his own making; they are, in one sense, inherent in the nature of the problems themselves. Towards the end of his book, he points out how fortunate the pursuers of inquiries concerning physical Nature are, in so far as their undertakings are relatively simple and they can avail themselves of the aid of the mathematicians. "They cannot quite conceal a certain disdain for those who conduct inquiries concerning that lesser mystery, man, whose baffling unity of composition is the very ground of their good fortune." Yet even the man of science may turn upon himself and experience some of the doubt and perplexity of the philosopher. "Those who pursue the physical sciences would do well to look with charity and humility upon those who seek to penetrate the mystery we confront because man is man, and because the conductors of inquiry are men." It is probable, at the present moment, that Descartes would obtain a more sympathetic and intelligent understanding of his problems from men of science than from the majority of philosophers, who would reject, out of hand, both solutions and problems as linguistic fallacies.

The title of this work is a little misleading. Except for the last four chapters, the author is not directly concerned with Descartes and present problems of science and philosophy. It is rather the beginnings and growth of the 'modern mind' which form the main subject of this work, and the concern is with Descartes as the father of 'modernity', at least as a first among equals. Prof. Balz is careful to point out that the transition from medievalism to modernity does not merely mean revolt but also conservation, not only change and destruction but also revision and redirection. The first four chapters are accordingly devoted to a discussion of the Augustinian and Thomistic doctrines, especially the famous distinction of Scientia and Theologia, which set the conditions under which Descartes must seek to launch the search for truth in the sciences. The next section describes this quest for certainty and is, in fact, together with the following section, a detailed analysis and exposition of the epistemological and metaphysical doctrines of the "Meditations". It is impossible, in the limits of a short review, to enter into the many points raised in these closely argued chapters. One original point of exposition may perhaps be mentioned. The name *Cartesius* is used to signify reason itself, and *René Descartes* used to describe the conductor of the inquiry who proposes to report what he has learned from Cartesius. This rhetorical device is used to avoid possible misconceptions which may arise from faults in Descartes's own method and devices of expression being confused with the logical structure and articulation of his philosophy. Given the patience requested by Prof. Balz, I was able to follow the elaborate discussion of the methodical doubt and the *Cogito* with comparative ease. Some readers may become slightly irritated.

The second part of the book is devoted to a discussion of the scientific doctrines of Descartes. It is as though the text commented upon was changed to the "Principia", but the emphasis is still upon the philosophical aspects. The mind–matter or soul–body problem is discussed in great detail, and this is one of the most rewarding sections of the whole work. The texts quoted are well known, but an original thinker throws new light on them without forcing or distorting their meaning.

The volume is magnificently produced, although it is somewhat expensive. Personally, I do not see the need for quoting the French texts in their old spelling, which may puzzle a few readers. Descartes himself was a careless speller and often expressed his complete indifference to orthography. Nothing is lost by modernizing the text. L. J. BECK

## Natural Gas and Natural Gasoline

By Prof. R. L. Huntington. (McGraw-Hill Chemical Engineering Series.) Pp. vii+598. (London: McGraw-Hill Publishing Co., Ltd., 1950.) 68*s*.

ONE of the earlier books on natural gas (Lichty, 1924) is still a favourite to consult on this subject. It is none the less instructive to read a new and up-to-date treatise, in this case extending to natural gasoline, for so much has happened in the evolution of this technology in the intervening time. The author is professor of chemical engineering in the University of Oklahoma where, incidentally, the other book was written. Naturally, appeal is to engineering students taking courses in the production of natural gas from crude oil, condensate, dry-gas fields, and the manufacture of various products from such new materials.

A wide range of cognate subjects is considered. The approach is to some extent academic; but practical field applications are by no means neglected. The course of instruction includes the estimation of gas and gasoline reserves; elements of plant location and design; gathering of raw gas and residue gas; a useful account of cycling efficiencies in the Cotton Valley (La.) gas-condensate reservoir; elements of natural-gas processing; and absorption, distillation, fractionation, dehydration, storage and transportation. That difficult subject, high-pressure pipe-line research, is treated with all the mathematical background necessarily entailed, and then the book concludes with a number of useful and practical appendixes, ranging from current specifications to methods of test.

This is a text-book which can be confidently recommended to oil technologists, both in the making and of ripe experience.

## Statistics for Medical and other Biological Students

By L. Bernstein and M. Weatherall. Pp. xii+180. (Edinburgh and London: E. and S. Livingstone, Ltd., 1952.) 18*s*. net.

THE introduction of statistical methods in medicine has to some extent been uphill work, so many practitioners by occupation, tradition and inclination being more concerned with the individual case-study than with the broad survey. It is now generally recognized, however, that the medical curriculum should include some elements of statistics. Drs. L. Bernstein and M. Weatherall have written this text-book on the basis of lectures and practical classes given by them to medical students in the first year of preclinical studies.

The development of the book follows fairly standard lines. Two chapters on scientific method and probability precede a set on frequency distributions and measures of location and dispersion. There follow three chapters on sampling, two on regression and correlation, and introductory chapters on transformations, the analysis of variance, experimental design, therapeutic experiments and the interpretation of observations. Much has had to be omitted, and a great deal more dealt with by passing reference, but these limitations are presumably imposed by the size of the book.

The authors have rightly concentrated on the logic of statistical methods and their use in medicine. The mathematics involved in the derivation of these methods have either been omitted or reduced to the point where they can be mastered by the use of elementary algebra. The result is very readable, and if the book does not carry the medical student as far along the path as a statistician would like to see him go—or as he must go if he needs to use statistical methods himself—it at least points his feet in the right direction and gives him a useful introduction to the statistical problems he will have to face.

## Practical Pharmacology

By Prof. J. H. Burn. Pp. viii+72. (Oxford: Blackwell Scientific Publications, 1952.) 12*s*. 6*d*. net.

IT would not be easy to invent at short notice a course of practical work for medical students. The experiments must arouse interest and have some relation to practical medicine; but they must also be fairly simple to perform and not take too long. Such courses grow gradually as the years go by; active teachers try out new methods and add the best of them to their repertoire in the place of older methods which have lost their original importance. The result of this process of evolution is an elaborate set of instructions which is issued to the students and contains the results of the accumulated experience of many years. These courses evolve on parallel lines in different places; but those who are responsible for them are always anxious to profit by the experience of others, and every teacher of pharmacology will be glad to have the chance of learning exactly what is done in the pharmacological laboratory in the University of Oxford, which is justly famous for its technical skill and the variety of its experiments.

Prof. J. H. Burn has written a clear account of eleven experiments on isolated organs, seven experiments on mammals with their circulations (but not their brains) intact, two on frogs and one on man. These experiments are all described in full detail, with clear drawings by Dr. E. M. Vaughan Williams, and a number of beautiful figures showing the results. A few of these experiments have been in all practical courses for a long time; but many of them are quite new, and it is clear that the Oxford pharmacologists have not been resting on their laurels. The book is so beautifully printed on glossy paper that it is a little sad to think that many copies of it will soon be exposed to all the dangers of the laboratory.

## Technical Publications, 1947

Pp. xi+499. (New York: Standard Oil Development Co.; London: Esso Development Co., Ltd., 1950.) n.p.

THIS second annual volume of papers, by members of the Standard Oil Co. (New Jersey) and five affiliated organizations in the United States, which were contributed to technical magazines during 1947, bears testimony to the talent and diligence, and also to what the president of the Company in his foreword picturesquely describes as the "aggressive research" of the scientific workers and engineers concerned. The volume is divided into papers on geology and production research, manufacturing research, production quality research, and analysis. The subjects range over the determination of oil in place and connate water; oil in Florida; ambiguity in gravity interpretation; palæogeography of South America; consolidation of sands in oil wells; retorting oil shale by fluidized solids; testing cracking-catalysts; liquid—and vapour—liquid extraction; naphthas from fluid catalyst cracking; butadiene resinous polymers; polymers and viscosity index; pour-depressant treated oils; butyl inner pneumatic tubes and tyre life; heat conduction in rubber-like polymers; synthetic elastomers as plasticizers for polyvinyl resins; infra-red spectroscopy in analysis of liquid hydrocarbons; determination of aromatics and naphthenes in complex mixtures containing olefins; Deniges reagent test for *tert*butyl and *iso*propyl alcohols; short-cut methods of infra-red analysis; and determination of antioxidants in gasoline. The book includes a challenging essay on the stake of business in American education, and closes with the mention of ninety-five other publications published in 1947 by members of the group.

## Journal of the Institute of Metals

Vol. 76, 1949–50. Editor: N. B. Vaughan. Pp. xxvi+796+113 plates. 30*s*. Vol. 77, 1950. Editor: N. B. Vaughan. Pp. xxiv+676+83 plates. 30*s*. (London: Institute of Metals, 1950.)

THESE two volumes contain fifty papers and (Vol. 76) a symposium of eight papers on metallurgical aspects of the hot working of non-ferrous metals and alloys, together with the presidential address, and the Autumn and May Lectures of the Institute of Metals. The range of subjects is wide, and all those connected with the science of metals will find much of interest.

It is instructive to examine the sources of the papers, which may be summarized as follows: British Non-Ferrous Metals Research Association, fourteen; universities of Great Britain, ten; Commonwealth Dominions, six; industrial, six; National Physical Laboratory, four; other British government laboratories, three; and research institutions, two. The symposium contains six papers from industrial sources, and one from the British Non-Ferrous Metals Research Association. When compared with the volumes of pre-war years, the increased output of this last-named Association is remarkable. The growth of the Dominion schools is encouraging, but the relatively small number of papers from British government laboratories is regrettable and may well affect the recruiting of first-class men for these institutions. The universities have maintained their position in difficult circumstances; but I feel that the Institute is failing to secure its proper share of papers dealing with the real fundamentals of the science of metals.

W. HUME-ROTHERY

## Smithsonian Logarithmic Tables to Base e and Base 10

Prepared by George Wellington Spenceley, Rheba Murray Spenceley and Eugene Rhodes Epperson. (Smithsonian Miscellaneous Collections, Vol. 118: Publication 4054.) Pp. xiii+402. (Washington, D.C.: Smithsonian Institution, 1952.) n.p.

THIS volume is divided into two equal parts, each consisting of two hundred pages. Every page is divided into three parallel columns containing, respectively, the logarithms of $n$, $1 + n.10^{-7}$ and $1 + n.10^{-11}$, where $n$ ranges through all integers from 1 to 10,000. Those to base $e$ (denoted by ln) appear in the first part, and those to base 10 (denoted by log) in the second part, all entries being given to twenty-three decimal places. In the tables of common logarithms the characteristics are omitted.

A four-page introduction exemplifies the methods of factorization which are most convenient for use in looking up the logarithm or antilogarithm of any given number. To quote a typical example, in which it is assumed that the computer has access to a calculating machine, one can express $\pi$, correct to twenty-three decimal places, as

$$3141 \times 1.0^{3}1886 \times 1.0^{7}8307 \times 1.0^{11}5638,\ 28195,\ 88209 \times 10^{-3}.$$

The first three factors can be converted into logarithms immediately, and the fourth factor is dealt with by replacing $\ln(1 + x)$ by $x - x^{2}/2$, and converting, if necessary, to a common logarithm in the usual way. By this method a result for $\ln \pi$ or $\log \pi$ is obtained which contains an error of one unit only in the twenty-third decimal place. In computing antilogarithms, it is, broadly speaking, only necessary to reverse the above procedure.

Finally, it may be said that the book is well bound and that the printing, though sometimes a little irregular, is always legible; there seems little doubt that, in the words of the preface, "the tables should be a welcome addition to those already in existence".

J. H. PEARCE

## Tensor Analysis

Theory and Applications. By Prof. I. S. Sokolnikoff. (Applied Mathematics Series.) Pp. ix+335. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1951.) 48*s*. net.

IN the first two chapters of this book, Prof. I. S. Sokolnikoff proceeds by way of vectors, linear transformations and matrices to the theory of tensors. The third chapter fulfils a dual purpose: it applies tensor methods to differential geometry, thus enabling the reader to assimilate the technique by applying it in a familiar field, and also collecting geometrical results which will be needed in the last three chapters. These deal with general dynamics, relativity and the mechanics of continuous media. The general dynamics is treated fully; the relativity is intentionally merely a sketch, since so many good accounts are already available. The author's deep interest in the theory of elasticity makes the final chapter exceptionally valuable. First he gives an analysis of deformation, based on the work of Brillouin and Murnaghan; but then, instead of assuming a linear stress–strain relation, he uses thermodynamical ideas to infer a general theory in which the classical linearized theory appears simply as a special case. A very brief note on fluid mechanics ends the chapter.

The exposition is clear and readable, and some exercises for the reader to work on are included.

## A New School Biology

By Dr. F. J. Wyeth. Part 1. Pp. viii+310+xvii. 9*s*. Part 2. Pp. viii+311–587. 8*s*. 6*d*. (London: G. Bell and Sons, Ltd., 1952.)

THESE two volumes are stated to be for pupils taking the Ordinary level of the General Certificate of Education; but it is to be regretted that the author has not considered the content nor the spirit of the syllabus, the time allocation nor the age of the pupils.

A book full of heavy type and italics is to be deprecated, since it indicates what must be learnt without reference to understanding. Facts abound, from the mechanism of the jaws of a snake to the minute structure of a diatom; digestion in some detail (with formulæ of proteins) but not a word about diet; everywhere there are details of structure and function, but little attempt to link any of it up with human affairs or make it stimulating.

On the whole, this book provides too much and too strong meat for children.

D. M. REID

# STRUCTURE OF ALGAL FLAGELLA

By Prof. W. T. ASTBURY, F.R.S., and Dr. N. N. SAHA

Department of Biomolecular Structure, University of Leeds

As a natural development of our work on the molecular structure of bacterial flagella, we have for some time now been engaged also in a similar study of algal flagella. Since this is likely to be long and involved, we believe it will be of value to set down without further postponement some of the findings, which have turned out to be so different from what was rather hoped from the relatively clear-cut results of the bacterial investigation. It will be recalled that the latter placed the essential substance of bacterial flagella (*Proteus vulgaris* and *B. subtilis*) in the keratin – myosin – epidermin – fibrinogen group of fibrous proteins and correlated the motility mechanism with the well-known folding and unfolding of polypeptide chains which is the basis of the long-range elastic properties of the group[1]. It was suggested, in fact, that bacterial flagella can be described as monomolecular hairs or muscles, a conclusion that has since been refined by the deduction from detailed analysis of the X-ray data that a more apt description still would be monomolecular *muscles*[2]. There is a large gap in size and apparent level of complexity between bacterial and algal flagella, as is at once evident from Fig. 1, an electron micrograph of a flagellum of *Euglena gracilis* showing also (inside the loop) a short length of a typically wavy bacterial flagellum about 120 A. thick; but even so, considering the much greater jump between bacterial flagella and hairs and muscles, it seemed not unreasonable to expect that algal flagella too might be found to fit just as readily into the scheme. However, present indications, while not of course ruling out the common broader molecular principles of biological elasticity and movement, are against the idea of any direct conformity with hairs and muscles, as will appear in what follows.

The algal flagella we have examined so far are of *Polytoma*, *Polytoma* 13, *Polytoma 2a*, *Polytomella magna*, *Chlorogonium elongatum*, *Euglena gracilis* and *Chlamydomonas*, pure strains of which, together with much valuable advice for which we are greatly indebted, were supplied by Dr. E. G. Pringsheim, of the Botany School, Cambridge. The flagella were detached, purified and collected by a combination of Gard's[3] shaking technique and centrifugation, and yields were obtained of about 5 mgm. per litre. These have been sufficient for our exploratory purposes; but a total of some 200 mgm. proved a severe limitation in the end, and it becomes necessary to work on a larger scale, as indeed we are now doing.

There are wide structural differences among the various kinds of algal flagella as seen in the electron microscope; but in spite of these differences, their X-ray diagrams are all more or less of the same type, revealing a main component common to them all. It was not found possible to make thin coherent films like those given by sols of bacterial flagella; the films obtained by deposition and drying of algal flagella, though hygroscopic, are brittle and only slightly oriented. Fig. 2, of *Chlorogonium* flagella, is an example of the best we have been able so far to accomplish in this respect—it is unfortunately little better than a powder diagram, albeit a surprisingly good one from such material.

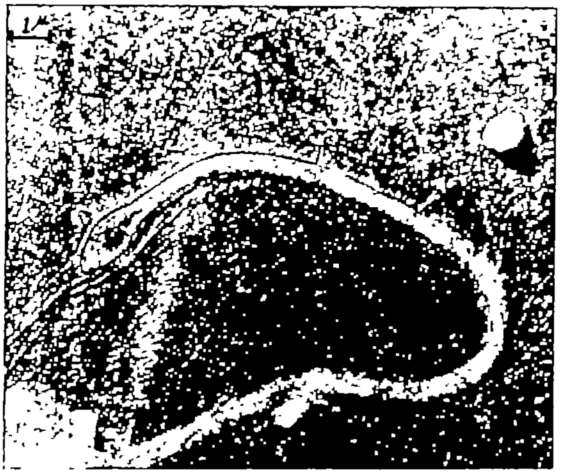

Fig. 1. Electron micrograph of a flagellum of *Euglena gracilis*, showing also, for comparison, a short length of a wavy bacterial flagellum

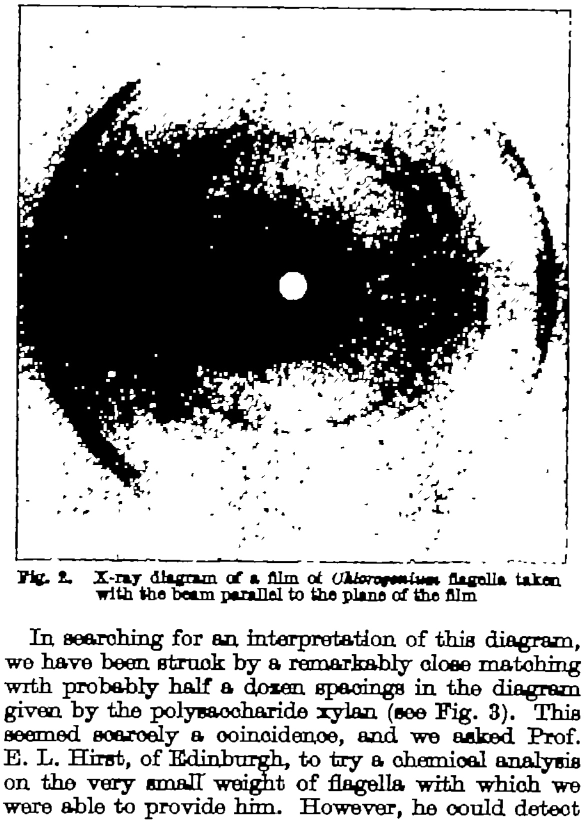

Fig. 2. X-ray diagram of a film of *Chlorogonium* flagella taken with the beam parallel to the plane of the film

In searching for an interpretation of this diagram, we have been struck by a remarkably close matching with probably half a dozen spacings in the diagram given by the polysaccharide xylan (see Fig. 3). This seemed scarcely a coincidence, and we asked Prof. E. L. Hirst, of Edinburgh, to try a chemical analysis on the very small weight of flagella with which we were able to provide him. However, he could detect no xylose nor any other carbohydrate in appreciable amount; but on the other hand, he reported that paper chromatography disclosed the presence of plenty of amino-acids. Dr. W. R. Middlebrook of this Department then repeated the analyses for protein and confirmed the presence of aspartic acid, X-RAY REFLEXIONS FROM ALGAL FLAGELLA

| Spacing (A.) Obs. | Spacing (A.) Calc. | Intensity | Proposed indices |

glutamic acid, lysine, arginine, glycine, alanine, valine, leucines, phenylalanine, methionine, serine and threonine; the acidic amino-acids predominating over the basic. He too was unable to demonstrate any carbohydrate, though it is felt that this is not a final verdict because of difficulties associated with the simultaneous presence of protein breakdown products. Dr. Middlebrook made also a couple of preliminary estimations of the nitrogen content, but he found only about 8 per cent; so very probably it requires something in addition to simple protein to account for the whole of the flagellar mass.

Our best X-ray diagrams (from *Polytoma* and *Chlorogonium*) show reflexions at the spacings given in the first column of the accompanying table.

These do not appear to correspond particularly closely with anything already familiar in either the protein or polysaccharide field, but in view of the largely protein nature of the flagella and present doubts about polysaccharide, we should like to suggest that the X-ray data accord best with a β-protein structure in a rectangular unit cell of dimensions: $a = 9\cdot3$ A., $b = 7$ A. (fibre axis), and $c = 14\cdot3$ A. It will be seen from the table that the agreement is quite good. The proposed structure diverges from that of β-keratin and denatured proteins in having (like silk fibroin) an amino-acid spacing of 3·5 A. instead of 3·33 A., and an unusually large side-chain spacing of 14·3 A. instead of 9·8 A. We have, of course, tried to substantiate this choice of axes by repeated efforts to produce sufficient orientation in the flagellar films, but so far with little greater success than to concentrate the 14·3-A. reflexion on the equator of photographs taken with the X-ray beam parallel to the plane of the film—a result which is by no means conclusive on its own, but which is distinctly favourable in combination with another observation made on a thin film that had been dried at 105° in the course of intramolecular swelling tests (see below). When this film was photographed with the beam first perpendicular and then parallel to its plane, it was noticed that the reflexion at 4·65 A. was a little stronger, and that at 14·3 A. a little weaker, in the former diagram, suggesting that the 4·65-A. spacing tended to lie parallel to the film, whereas the 14·3-A. spacing tended to stand perpendicular to it.

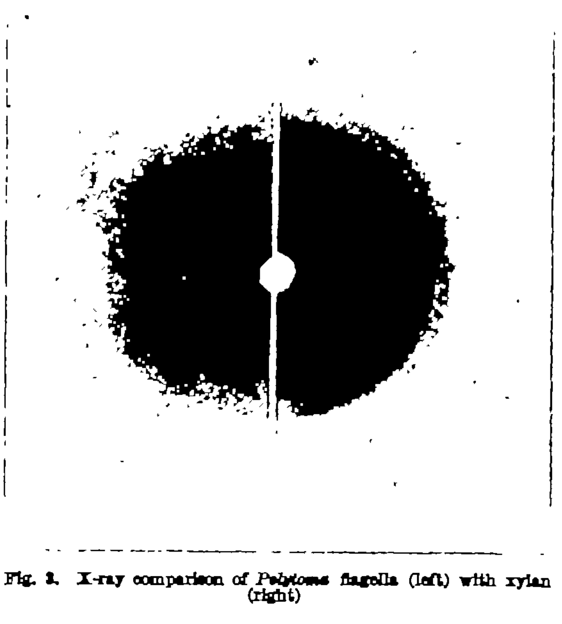

Fig. 1. X-ray comparison of *Polytoma* flagella (left) with xylan (right)

As just mentioned, we have also tried to demonstrate differential intramolecular swelling of the postulated side-chain spacing, but again without success. Contrary to expectation, no change at all could be detected in this respect between dry and wet flagella.

A considerable part of the flagellar substance is soluble in aqueous ammonia (0·1 *M* was used), and it was found then, after centrifuging, that preparations made from the supernatant gave once more practically all the original reflexions; while the insoluble residue gave a much poorer diagram, still similar though, but with greatly weakened side-chain and backbone reflexions and a moderate new reflexion at about 9·6 A.

Complementary experiments to those with ammonia were carried out by adding a few drops of *N* hydrochloric acid to a small amount of flagella on a glass slide and leaving to dry. The X-ray photograph of this sample now showed two kinds of reflexions, one very 'spotty' such as may be obtained from salts and other substances of low molecular weight, and the other continuous rings which proved on closer examination to be strengthened counterparts of certain extremely weak reflexions in the original flagellar diagram. On adding ammonia, this change brought about by acidification tends to be reversed, the 'spotty' rings gradually disappearing and those of the ammonia-soluble structure coming back again.

Another curious result was obtained after heating a sample of wet flagella to about 95° to see whether the orthodox β-diagram of heat-denatured proteins would be produced. What happened was that certain 'spotty' rings appeared quite close to the positions of some of the original continuous rings, as if there were being generated a product of small molecular weight structurally related to the β-protein.

From the above tests (all performed on quantities of material too small for anything like completeness) we have gained the impression, first, that the full diffraction diagram possibly arises from more than one component, and secondly, that the protein side-chains are probably combined with, and perhaps cross-linked through, accessory atoms or groupings. Actually, the 'spotty' (low molecular-weight) lines found after the action of hydrochloric acid show a fair correspondence with the strongest lines in the powder diagram of $CaCl_2,2H_2O$, so it may be that the acid liberates carboxyl groups cross-linked through calcium or other divalent ions. An alternative explanation that the acid hydrolyses the protein seems excluded by the reversibility of the effect when ammonia is added.

We are indebted to Mr. K. D. Parker of this Department for a number of helpful observations made by infra-red spectroscopy. The absorption spectrum of a thin film of *Chlorogonium* flagella shows the expected general resemblance with that of dried stretched horse-hair (β-keratin); but it is at once apparent that additional factors have to be invoked to account for the former in detail (see Fig. 4). For example, in the region where β-keratin gives the bands at 1,625 cm.$^{-1}$ and 1,650 cm.$^{-1}$ associated with the C=O stretching mode, and the bands at 1,520 cm.$^{-1}$ and 1,550 cm.$^{-1}$ probably due to the NH deformation mode, the flagella give a relatively smooth hump together with a strong band at about 1,400 cm.$^{-1}$. On acidification with hydrochloric acid the latter is eliminated, a depression appears round about 1,600 cm.$^{-1}$ with the result that the CO and NH bands are now unmasked, and a strong band appears at about 1,730 cm.$^{-1}$ together with increased absorption in the region 1,250 cm.$^{-1}$. Strong absorptions at 1,740 cm.$^{-1}$ and 1,250 cm.$^{-1}$ are known to be associated with un-ionized COOH groups, in contradistinction to bands at 1,600 cm.$^{-1}$ and 1,400 cm.$^{-1}$ associated with ionized COO$^-$ groups; so one difference at least between the flagellar protein complex and β-keratin would seem to lie in a relative abundance of carboxyl groups in the former (cf. the predominance of acid amino-acids in the chromatogram after hydrolysis). This inference was further strengthened by comparisons with sodium alginate and alginic acid, which showed very strikingly the change-over just mentioned from ionized COO$^-$ groups to un-ionized COOH groups[4]. A small effect of a similar kind was also observed on treating horse-

Fig. 6. Electron micrograph of a coiled-up flagellum of *Polytomella magna*

hair with hydrochloric acid. Incidentally, the flagellar spectrum was found to have little in common with that of xylan except for absorption in the region 950–1,200 cm.$^{-1}$, where xylan has strong bands characteristic of carbohydrates. This might be an additional suggestion of the presence of sugar rings of some kind in the flagella. Another noteworthy observation in what looks like the same connexion was made in a comparison of the ammonia-soluble component with the insoluble residue: as with the X-ray comparison described above, the infra-red spectrum of the soluble product was similar to that of the original material, but the insoluble residue showed an increased absorption from about 950 cm.$^{-1}$ to 1,200 cm.$^{-1}$ relative to the absorption from about 1,500 cm.$^{-1}$ to 1,700 cm.$^{-1}$.

Several workers have reported already on electron microscope studies of various flagellates[5], and we ourselves, with the help of Mr. A. Millard, have been content so far with a limited number of micrographs largely for purposes of guidance in the preparative techniques and in relation to the deeper molecular aspects. As noted near the beginning of this article, there are seen in the electron microscope differences in gross morphology that must be secondary to the essential molecular unity indicated by X-rays. An important feature frequently observed is, of course, the longitudinal splitting characteristic of fibre structure. Fig. 5, for example, shows the disintegration of *Polytomella magna* into nine principal fibrils (the original flagellum being about 2,500 A. thick and each fibril about 350–375 A. thick), though this is soon accompanied also by transverse breakage. In some pictures of *Polytoma* the longitudinal splitting is seen to be proceeding to finer threads still; and another common observation is of the tight bending, illustrated in Fig. 6, that appears to be brought about particularly on washing with distilled water. Altogether, what with this coiling-up and eventual longitudinal splitting and transverse disintegration too, it is not surprising that films of such flagella should be so brittle and unresponsive to orientation techniques.

It is tempting to speculate on the molecular basis of the motility mechanism; but the data are not enough yet for any really convincing argument, especially in view of the seeming wide dissimilarity from bacterial flagella. There is nothing in the available evidence in favour of a quasi-rigid flagellum beating about a hinge near its insertion, and we have to find some counterpart to the transition between the α- and super-contracted states to which we have ascribed the bending movements of bacterial flagella. Probably the best guess for the present is that there is a β-structure normally stabilized by cross-linkage of carboxyl groups through calcium or other divalent ions, and that the cross-linkage is periodically broken down, for example, by exchange with monovalent ions. This would give the chains a freedom of movement that could result in an entropic shortening, as in the experiments described by Mongar, Wassermann and MacArthur[6]. These authors observed contractions of up to 20 per cent when calcium alginate fibres were treated with solutions of sodium or other monovalent metal salts. To cause a flagellum to bend into the required form, the interchange between extended and shortened chains would, of course, have to be suitably distributed, in both time and place, among sub-units of the structure; but there is no obvious difficulty about that, considering the way each flagellum is built up from finer fibrils. Sufficient of the latter are recognizable in some kinds of flagella to provide a framework not merely for a side-to-side beating movement but also, if necessary, for a continuous spiral wave.

The idea of chain-molecules normally held straight by cross-linkages is supported by the sharpness of the supposed side-chain reflexion, its unusually high spacing, its unchanged character on wetting, and the chemical evidence for something in addition to simple protein; while the X-ray suggestions of calcium already mentioned are strengthened by spectrochemical tests kindly carried out for us by Dr. R. L. Mitchell, of the Macaulay Institute for Soil Research, Aberdeen. He found, among traces of other metals, a fair amount of sodium, calcium and magnesium, with a relatively small amount of copper, though unfortunately the sample of flagella we were able to send him was too tiny for reliable quantitative estimations.

We are now proceeding to remedy this trouble of having too minute quantities of material, and we hope to be in a position shortly to re-investigate with much more thoroughness all the points and possibilities raised in this preliminary article. At the least, however, it will be granted that we have caught a glimpse of a most fascinating new field in molecular biology that invites exploration with all the intensity and resources at our command.

# CHINESE SCIENCE REVISITED (2)

By DR. JOSEPH NEEDHAM, F.R.S.

IN the second of these two articles, the attempt will be made to indicate some of the particular emphases which exist in the Chinese scientific world of to-day. There is, in the first place, an emphasis on practical tasks. In a country where so much modernization has been needed, this is inevitable; but it does not mean that theoretical studies are being neglected, for they are fed by practical experience, and the latter alone, it is felt, can keep them along the right lines. Secondly, there is an emphasis on teaching, since the need for properly qualified specialists (or 'cadres' as they are called) is so pressing. Thirdly, there is an emphasis on popular enlightenment, and the bringing of science and the scientific outlook to the vast masses of the people. Lastly, something should be said about the philosophy of science and the kind of researches which have been noteworthy in the past three years.

At the end of the last article there was mention of geological survey parties—eighty-three of these were in the field during 1951. But the geologists have also given essential service in the physio-topographical surveys of areas where railway construction and river conservancy work are progressing. Without them the Lunghai railhead would not have reached Lanchow ten months ahead of schedule, as it did; without them the astonishing progress could not have been made with the Huai River Project. In this scheme, which will solve the problem of a great river (between the Yangtze and the Huang Ho) for generations to come, sixteen large retention-basin dams are being constructed on the upper tributaries in the provinces of Honan and Anhui. Some are already finished, and the whole project will be at least on the scale of the famed Tennessee Valley Authority.

In other cases, parties of scientific men of very varied specialities have taken the field. For example, a party of no less than fifty experts proceeded to Lhasa to see what could be done to assist the Tibetans in improving their conditions of life. This group included agronomists, soil scientists, geologists, geographers, meteorologists, sanitary engineers and medical men, ethnologists (for example, Li An-Chê) and historians. Another large party, including gynæcologists and child welfare experts, visited the minority peoples of Sinkiang.

The current emphasis on practical tasks can be seen in all fields. In some, the results produced can be spectacular. The cotton aphid (*Aphis gossypii* Glover) has long been a great pest in the cotton-growing regions of southern Hopei and the newly-formed province of P'ing-Yuan. But its life-cycle was not well understood. After several months of travel and research in the regions concerned, Chu Hung-Fu and his colleagues of Academia Sinica were able to ascertain that this aphid passes the winter attached underground to the roots of a common weed *Lactuca* or *Ixeris chinensis versicolor*. It is now possible, therefore, to eradicate it almost completely; this is all the more important a discovery because the pest is rather resistant to known insecticides. While I was visiting the Academy's Entomological Laboratory, reports came in of the first successful large-scale use (1951) of gamma benzene hexachloride against locusts, spread from aeroplanes in southern Hopei and Anhui. Many of the new substances for insect control, such as *E*-605,666, 'Gammexane', etc., are now made in China.

As for the emphasis on teaching, it can be seen in all fields. For the time being, research is concentrated rather in the institutes and laboratories of the Academy, though it goes on to a minor extent in university laboratories; this is regarded as a passing phase, for the general principle that the latter should also be active research schools is fully admitted. Planned expansion in geology, for example, is remarkable—where there were 35 students in 1951, there were 120 last year, and for this year 1,000 are being planned for. The Medical College of Peking University, and the National Medical College at Shenyang (Mukden), formed by the additional absorption of the former Scottish and Japanese schools, are indeed impressive in their size and vitality. According to Dr. Hu Chuan-Kuei, principal of the Peking University Medical College, which has forty years of history, the student numbers rose from 400 in Kuomintang times to 1,400 at the present day. This includes 260 students in pharmacy, 160 in dentistry, 140 in public health, 40 in nursing and 40 in midwifery. The total number of qualified medical men in China is of the order of 50,000; but ten times this number are urgently needed to give one per thousand of the population. Of the 2,300 hsien cities in China, however, already more than 1,800 have their own State clinic or hospital. Besides the mobilization of old-style practitioners as auxiliaries, already mentioned, there has been a cutting down of the total time needed to qualify. The full qualification will still take five years; but medical assistants are being turned out after a two-year course, and technicians of various kinds need even less. The compression of the curriculum has been done by omission of matters which are unlikely to be met with by the Chinese medical man, for example, the tropical diseases of South America. All teaching is now done in the Chinese language. I saw, as evidence of recent developments, a finely produced new text-book of general pathology based mainly on Chinese material, and in Chinese, by Hu Chêng-Hsiang and others. Of course, the Peking University Medical College is not the only one in the capital; the Peking (now the Chinese) Union Medical College is also functioning intensively.

Both for research and teaching, Chinese scientific workers now have facilities incomparably greater than those which used to be available during the confusion and blockade of the Second World War. A great many instruments are now being made in the big cities such as Shanghai. In Academia Sinica laboratories, I saw excellent incubators and refrigerators, a variable-temperature insect-behaviour chamber, vacuum pumps, mechanical stirrers, shaking machines, ball mills and glassware, all made in China. A kind of 'Pyrex' ware is also locally available. Microtomes have been constructed by the Chinese Union Medical College workshops. At the Shenyang Medical School a consignment of two hundred teaching microscopes from East Germany had just come in during one of my visits, and my friends in the National Academy were making much use of East German catalogues. If normal conditions of trade can be restored, as all must hope, China would doubtless be glad to receive British scientific instruments. Heavier kinds of equipment are often Soviet in origin, and the Chinese are making excellent use of them.

Another emphasis which must be mentioned is that on popular education. There is a touching and genuine thirst for scientific knowledge among the Chinese people. Shops which sell anatomical models and geological charts have a crowd around the windows all day. If the visitor from the West wanders into one of the modern bookshops on a Sunday, he will almost have to step over rows of children and boys and girls of various ages sitting on the floor and against the bookcases reading popular science, and not paying the slightest attention to him. The assistants never insist on readers buying books, though they usually do, as they are relatively extremely cheap. I visited a popular exhibition of astronomy in the beautiful Pei Hai Park in Peking. It was packed with ordinary people, to say nothing of the usual large proportion of school-children, who were delighted with a simple form of planetarium. Most justifiably there were special panels accurately relating the ancient and medieval contributions of the Chinese to astronomy, such as the invention of the equatorial mounting by Kuo Shou-Ching in A.D. 1279; and the young man who was demonstrating these was delighted that a Western visitor was already familiar with these contributions and could even elaborate on them. Of great interest also was an exhibition of army education set up in the buildings surrounding the exquisite Temple of Heaven; here there were many pieces of simply constructed apparatus for demonstrating fundamental principles of physics, optics and the like; or, to take another example, out-patients passing through the corridors at China Union Medical College would pause to look at illuminated model scenes inset into the walls, which explain the cycles of transmission of the chief helminthic infections known in the Chinese countryside. Will it not make some difference to the world that five hundred million people are awakening to the significance of natural science and all that that implies ?

Next, something may be said of a few of the researches which have been proceeding during the past three years. Stimulated by the importance of ethyl mercury chloride as a fungicide, the Institute of Physical Chemistry of the Academy has been studying the role of catalysts in the formation of this and similar compounds. The Institute of Organic Chemistry has been working on plant hormones and possible new antibiotics derived from certain plants traditionally used in Chinese medicine. From the point of view of economy it would obviously be of advantage to use as many of these as possible, and they are now undergoing more extensive study by modern methods than ever before ; the China University Medical College, for example, has a special department for the investigation of Chinese materia medica. In physiology there has been work on micro-analysis of potassium, sodium and phosphorus in nerve tissue during activity. The Laboratory of Developmental Physiology has completed researches on the structure and mode of action of the eye-stalk hormone of Crustacea, and has isolated an active substance in the form of its cadmium complex. Systematic botany and zoology are being actively pursued by many workers ; often in connexion with important practical problems, such as forestry, fisheries, and the epidemiology of rodent-borne plague. The palæontologists have been studying fossils of dinosaurs and their eggs at Laiyang in Shantung Province. They have also conducted large-scale excavations in the Choukoutien area near Peking in connexion with *Sinanthropus pekinensis*, the precious specimens of which were lost during the confusion of the Second World War, and are widely believed to be still in American hands. Palæobotanists have been concentrating on the mesozoic fossils of the Szechuan basin, and the redwood fossils in the coal beds of Fushun in southern Manchuria. Important work has been done by the Metallurgical Institute on new kinds of nodular graphite cast iron with superior strength and properties favourable to mechanical treatment. Its Kunming branch laboratory has been occupied with problems relating to the bauxite deposits of Yunnan province, and similar local needs. In so short a review as this it is, of course, impossible to do more than allude to a few of the subjects on which research is proceeding.

In conclusion, a few words may be said regarding the philosophical point of view of Chinese science to-day. In accordance with the world-outlook which has triumphed in China, Chinese scientists are greatly interested in dialectical materialism. The fact that there is very little opposition to it is noteworthy, and arises from several causes. There was never any strong strain of metaphysical idealism, such as that represented by Eddingtonian views, in Chinese thought. On the contrary, its finest formulation by the school of Chu Hsi in the Sung dynasty (twelfth century A.D.) was remarkably congruent with dialectical materialism, for this school worked with but two concepts : *ch'i*, matter, including its most tenuous forms, and *li*, the pattern or organization of things. These patterns were explicitly recognized to be arranged in levels of organization. For this world-picture dialectical materialism may readily be considered a continuation. In other words, the age-old and refined conceptions of Chinese humanism are fusing with dialectical materialism without that stress and strain felt in a Europe which has so long been the battlefield of irreconcilable opposites—either theological spiritualism, or atoms and the void.

# OBITUARIES

## Prof. F. E. Weiss, F.R.S.

The death of Frederick Ernest Weiss on January 7 at the age of eighty-seven severs one of our last direct links with the great men who, in late Victorian times, created the science of biology in Britain. The son of parents who were outstanding for their strength of character and high principles, he was born in Huddersfield on November 2, 1865. When he was seven years old his father died, and his mother with five young children moved, first to Heidelberg and later to Neuchâtel, to obtain a good education for her family.

Returning to England, Weiss entered University College, London, in 1884, with the object of taking a degree in botany ; but in his first year he came under the spell of Ray Lancaster and devoted much of his time to zoology. He learned his botany from Prof. Daniel Oliver, D. H. Scott and, in his third year, from Prof. Frank Oliver, who had just come from Cambridge to succeed his father in the chair. After graduation, Weiss spent some time at Naples in research on *Amphioxus*, but returned to the study of botany as Quain student and lecturer in botany at University College. Three years later he was appointed professor of botany in Owens College, Manchester—now the University of Manchester—in succession to W. C. Williamson, the famous palæobotanist. Weiss held this chair until his retirement in 1930, and was responsible for the erection of new laboratories, and for the creation of a notable school of botanical study and research from which many well-known botanists originated.

Weiss followed his predecessor at Manchester in carrying on research on the structure of Carboniferous plants, especially on their root systems ; but he also carried out investigations on pollination, seed dispersal, genetics and on graft hybrids. He took a keen interest in the study of vegetation, assisting in the work of the British Vegetation Committee and later in the foundation of the British Ecological Society, of which he was president during 1924–25. He devoted much of his time to the development of the botanical department of the Manchester Museum, and for many years gave a course of popular lectures in connexion with the Museum. His services to his University were considerable. Besides long periods of membership of its Council, he often acted as pro-vice-chancellor and served as vice-chancellor during two critical years, 1913–15. The appreciation of his work was shown by the award of the honorary degree of LL.D. He was a faithful supporter of the British Association, and was president of Section K (Botany) in 1911. He became a Fellow of the Royal Society in 1917, and served on its council.

After retiring from his chair at Manchester, Weiss moved to the neighbourhood of Guildford and spent much of his time at the garden of the Royal Horticultural Society at Wisley, where he was chairman of the Scientific Committee. He was a member of the Council of the Society for two periods between 1935 and 1946 and served on its Library and its Scientific Committees, as well as on its Examinations Board. His service to horticulture was recognized by the award of the Victoria Medal of Honour in 1947. He also devoted much time to the Linnean Society, serving as its president during 1931–34. In 1937 he was president of the South Eastern Union of Scientific Societies.

Weiss was a man of exceptional charm and kindness, combining wisdom and experience with modesty and tact; he was loved and respected by all who had the privilege of knowing him. He had wide interests, not only in science and education, but also in social betterment and in the improvement of Manchester and its surroundings. He took and maintained an unfailing interest in the welfare of his students and younger colleagues; he was always ready to give them help and advice. In all his many interests and projects he was helped by his wife Evelyn, third daughter of the Right Hon. Dr. Robert Spence Watson, whom he married in 1898, and who, with their three daughters, survives him.

H. Hamshaw Thomas

## Sir James French

We regret to record the death of Sir James Weir French, which occurred at his residence in Glasgow on January 14, at the age of seventy-six. James Weir French was born in Glasgow in April 1876 and was educated at Bearsden Academy and the University of Glasgow, where he graduated as B.Sc. in 1898; the degree of doctor of science was conferred on him some years later. While still at the University he entered the firm of Barr and Stroud and was appointed a director when the firm became a limited company in 1913. He was chairman of the firm from 1938 until he retired in 1949.

Sir James French had travelled widely and had gained considerable technical experience abroad. After the First World War, he was attached as an expert to the Inter-Allied Control Commission in Germany. He was knighted in 1941 in recognition of his contribution to the equipment of the Fighting Services.

Among important offices held by Sir James French in academic and scientific institutions and societies, he had been chairman of the governors of the Royal Technical College, Glasgow, president of the Royal Philosophical Society of Glasgow and lay chairman of the Glasgow Art Club.

Sir James's main energy was devoted to the design and development not only of the scientific instruments manufactured by Barr and Stroud, but also to the special optical machinery and materials necessary for their manufacture. During the First World War, when supplies of optical glass became critical, he was associated with the late Prof. Barr in the development and production of optical glass suitable for the highest standard of optical instruments. The subsequent large-scale production for the firm's instruments was largely due to his energy and initiative in devising the manufacturing processes and designing and constructing the necessary plant and equipment.

Sir James French published many scientific papers, chiefly on optical subjects; but his wide and detailed knowledge of the history of glass and porcelain, including those of ancient Egypt, made his papers on this subject of particularly wide interest.

## Prof. J. S. S. Brame, C.B.E.

John Samuel Stafford Brame, who died on December 10 at the age of eight-one years, was an authority on fuels and lubricating oils. He was educated at St. Thomas Rich's School, Gloucester, and commenced his scientific studies and training at the Royal College of Science. In 1897 he joined the staff of the Royal Naval College, Greenwich, as an assistant to Prof. V. B. Lewis, who held the chair of chemistry. The latter so greatly influenced Brame that under his guidance he specialized in oil technology and combustion, especially that of oils in furnaces; Brame here laid the foundation for his life's work. This association with Prof. Lewis, a founder member of the Institute of Petroleum Technology, finally brought him to the highest position in this field, namely, president of the Institute.

When Prof. Lewis resigned from the chair of chemistry in the Royal Naval College in 1914, Brame was appointed as the first professor of chemistry and metallurgy, a position which he held until his retirement from the College in 1932. During the whole of this period he lectured upon petroleum in all its aspects, and carried out investigations connected with lubrication, combustion, etc. When it was proposed to use oil as a fuel for the Royal Navy, Prof. Brame took a keen interest in this proposition; he carried out experiments on the numerous oil-burning locomotives of the (then) Great Eastern Railway, and from this experience was able to indicate certain conditions for the burning of oil on ships.

On leaving the Royal Naval College, he was appointed a director of Messrs. Alexander Duckham and Co., Ltd., lubrication oil specialists, and held the position of technical adviser until 1939.

For many years Prof. Brame lectured at the Sir John Cass College, London, on oil technology. These lectures were considered a very important part of the educational system devised and financed by various oil companies for the training of their staffs.

During his activities at the Royal Naval College and at the Sir John Cass College, Prof. Brame held many important posts, including the chairmanship of the Standardization Committee of the Institute of Petroleum Technologists, a subject in which he was always interested. He was a Fellow of the Royal Institute of Chemistry, and of the Chemical Society. He was made a Commander of the Order of the British Empire in the New Year's Honours, 1930.

F. A. Ruddock

We regret to announce the following deaths:

Prof. Paul Niggli, professor of mineralogy and petrology in the University of Zurich and in the Swiss Federal Institute of Technology, Zurich, and also *correspondant* for the Mineralogical Section of the Paris Academy of Sciences, aged sixty-four.

Lieut.-Colonel J. S. Vorley, C.B.E., director of national parks, Southern Rhodesia, and formerly of the Indian Forest Service, on January 2, aged fifty-four.

# NEWS and VIEWS

## Institution of Electrical Engineers : Awards

Sir Harry Railing has been elected to honorary membership of the Institution of Electrical Engineers for his services to the electrical engineering profession and to the science, and for his services to the Institution. The Faraday Medal of the Institution has been awarded to Sir A. Stanley Angwin for his outstanding contributions to the development of telecommunications in Great Britain and in the international and inter-continental fields.

### Sir Harry Railing

Born in 1878 and educated at the University of Munich, Sir Harry Railing received his early training and practical experience on the Continent of Europe and in the United States. In 1905 he went to the Witton Engineering Works of the General Electric Co., Ltd., to take charge of the test department and laboratories, and in 1911 he was made a director and placed in charge at Witton, where he remained for twenty years, a period of rapid expansion and development. In 1933 he left Witton for London, although he continued to control the organization of the Witton Works, and in 1941 was appointed joint general manager of the Company, becoming successively vice-chairman and then chairman and joint managing director. He was knighted in 1944. Sir Harry became a member of the Institution in 1912 and has held numerous offices, including the presidency (1944). He was also chairman of the Council of the British Electrical and Allied Manufacturers' Association during 1944–45 and was elected president last year.

### Sir Stanley Angwin, K.B.E.

Sir Stanley Angwin was born at Penzance in 1883 and was educated at Queen Mary College, London. After being a pupil of Messrs. Yarrow and Co., engineers and shipbuilders, he joined the Post Office Engineering Department in 1906. During the First World War he served in the Middle East and France in the 52nd (Lowland) Divisional Signals and was awarded the M.C. and D.S.O. He then returned to the Post Office Engineering Department, joining the wireless section, which at that time was being expanded, and played a major part in the design and construction of the Leafield, Cairo and Rugby radio stations and in the inauguration of the trans-Atlantic telephone service. Sir Stanley became assistant engineer-in-chief of the Post Office in 1932, deputy engineer-in-chief three years later, and then engineer-in-chief during 1939–46. During the tenure of this last-named post, for the most part held during the stress of war, many significant technical developments took place, including the introduction and expansion of the short-wave overseas radio-telephone services which have given Great Britain so important a position in world telephony, and the adoption of the coaxial cable system as a normal method of providing trunk-line communications. Sir Stanley was knighted in 1941 and received the K.B.E. in 1945. He was president of the Institution of Electrical Engineers in 1943.

## Experimental Physics in University College, Dublin: Prof. T. E. Nevin

Dr. T. E. Nevin, who has succeeded the late Prof. J. J. Nolan in the chair of experimental physics in University College, Dublin, graduated in the National University of Ireland in 1927. His first research was done on atmospheric electricity, under Prof. Nolan. In 1929, however, he was awarded an 1851 Exhibition, and during the tenure of this, under Prof. A. Fowler at the Imperial College of Science and Technology in London, and afterwards in Dublin, he has made many important analyses of band spectra. University College possesses a 21-ft. Rowland grating which has been used by him to unravel some very complex spectra, including negative bands of oxygen and bands of manganese hydride and deuteride. Prof. Nevin has also constructed a very large vacuum spectrograph, which is likely to come into use shortly. In recent years he has made experimental investigations of cosmic rays, in association with Prof. C. B. E. McCusker, of the Dublin Institute for Advanced Studies. Prof. Nevin has been a member of staff of the Physics Department of University College since 1931. He was elected to membership of the Royal Irish Academy in 1942, and has twice been a member of its Council. Since 1943, he has been a member of the governing board of various schools of the Institute for Advanced Studies, Dublin, and has delivered lectures on special topics under the auspices of the Institute.

## Mathematics at the Royal Technical College, Glasgow : Dr. D. C. Pack

The governors of the Royal Technical College, Glasgow, have appointed Dr. Donald Cecil Pack, lecturer in mathematics in the University of Manchester, to the chair of mathematics in the College. Dr. Pack won an open scholarship in mathematics to New College, Oxford, and took his B.A. with first-class honours in mathematics in 1941. The degree of D.Sc., for a thesis on a subject in the field of compressible flow and shock waves, was conferred on him by the University of St. Andrews in 1951. In the Second World War he served with the Ordnance Board during 1941–43, working on ballistics and the trajectories of shells. Later, as a scientific officer with the Ministry of Supply, he was engaged in research on gas dynamics with particular reference to supersonic flow and the effect of shock waves. He was also concerned with researches on problems relating to the penetration of armour. When the War ended Dr. Pack spent some time on supersonic research at the German supersonic station at Volkenrode. He is the author of numerous publications in the field of gas dynamics, supersonic flow, propagation of shock waves and related problems. During 1947–51 he was a lecturer in mathematics in the University of St. Andrews, and during 1951–52 was a visiting research associate professor at the University of Maryland.

## Atomic Energy for Industrial Power and other Uses

In reply to a question from Mr. Hector Hughes in the House of Commons on January 26, as to what progress had been made in British national research stations towards solving the problem of using atomic energy for industrial, travel and other peaceful purposes, the Minister of Supply, Mr. Duncan Sandys, said that the novel problems raised in the production of electrical power from atomic energy have been studied in the light of experience gained with the graphite piles at Harwell and at Windscale. Valuable discussions have also been had with Canadian experts about the results obtained in the operation of their heavy-water reactor at Chalk River, Ontario. The most certain method of generating power from atomic energy would be to build an improved type of natural uranium reactor enclosed in a pressure shell, the heat produced being transferred by a gas under pressure through a heat-exchanger to a conventional electric-power generator. As a by-product, this would yield plutonium, which could be used as fuel for further reactors. The potentialities of such a reactor are being studied, and, if the prospects prove favourable, the construction of an experimental atomic-power station of this kind would be considered. At the same time, continued Mr. Sandys, it is hoped to develop reactors of a more advanced type, known as 'breeder-reactors' by reason of the fact that they are designed to produce more fissile material than they consume. To facilitate the study of these methods, a small experimental reactor of this kind is being built at Harwell. This should be completed in a few months time, and work is proceeding meanwhile at Harwell and Risley on the design and development of a full-scale breeder reactor, capable of producing substantial amounts of electricity. A suitable site for the construction of this plant is being sought.

A natural-uranium reactor moderated with heavy water is also being built, which will produce a much more intense flow of neutrons than is possible with the present equipment. This reactor is for research work and will not be used to generate power. It will, however, greatly expand the quantities and variety of radioactive isotopes which can be produced for industrial, scientific and medical purposes. This project will take about four years to complete. It is not proposed to undertake work on the application of nuclear energy to propulsion until more experience has been gained in the development of stationary nuclear power plants. Mr. Sandys pointed out that it is too early to say with any precision how soon electricity generated from atomic energy will be available on a significant scale for industrial purposes. Nuclear reactors will certainly not supersede existing methods of producing electric power in the near future; but if the technical problems are solved and the new methods prove to be economical, there is no reason why nuclear reactors should not, before very long, provide a useful additional source of industrial power.

## Increased Expenditure for Research and Development by the Ministry of Supply

IN presenting a Supplementary Estimate for the Ministry of Supply in the House of Commons on January 26, the Minister, Mr. Duncan Sandys, said that the need for the Estimate arises mainly from the increased rate of expenditure on research and development: expenditure for that purpose is expected to exceed by about £21 million the £128 million originally provided. Some of the increased expenditure is due to rises in prices and wages, but in the main it provides evidence that the progress of the technical and scientific establishments of the Ministry, and of the industries working with it, has been more rapid than was expected. A special effort has been made to accelerate the development of new types of air-frames, aero-engines, electronic equipment and improved methods of jet propulsion. Further encouraging progress has been achieved in work on guided rockets, and Mr. Sandys added that there is no doubt that the guided rocket is one of the decisive instruments and will come to dominate the military scene. To hold back our scientific workers or technicians in this vital field would, he said, be false and dangerous economy. The successful atom-bomb test at Monte Bello, continued Mr. Sandys, completed an important phase in our programme of atomic research and opens a wider horizon for further scientific activity. With the progress made in studying the peaceful applications of atomic energy, it justifies an expansion of our development programme in this field, and the unexpectedly rapid progress with processes of extracting uranium as a by-product from gold-mining in South Africa and the encouraging developments in uranium production in Australia have also increased expenditure on atomic energy. About £5 million out of a Supplementary Vote of £5·85 million under "Works Services" relates to research and development establishments and arises out of this programme.

In the debate on the Supplementary Estimate, numerous questions were pressed for further information, more particularly in regard to the expenditure on research. In his reply on the debate, the Parliamentary Secretary to the Ministry of Supply, Mr. A. R. W. Low, while declining to break down further the figures for the expenditure on research, particularly the £9·9 million under Subhead *B*3 for research and development work by industry, extra-mural research at universities and the like, agreed that the Vote would include some research work for civil purposes as well as some on atomic energy. He said that he is satisfied that, where there are overlapping problems, there is consultation with all those concerned. No answer was given to Mr. Emrys Hughes's request for a clearer indication as to what is understood by research, or to Mr. F. Lee's inquiries as to the steps taken to facilitate the application to industry of the results of research at the earliest possible moment or as to the numbers of scientific workers and technologists engaged in research and the capacity of the universities to supply them.

## National Institute of Sciences of India: Presidential Address, 1952

IN his presidential address to the National Institute of Sciences of India, given on October 4, 1952, at the Museum House, Calcutta 13, Dr. Sunder Lal Hora dwelt on a number of topics pertaining to science in India. He first mentioned his pleasure that the three scientific Surveys of India—Geological, Zoological and Botanical—should recently have been grouped under one Ministry, that of National Resources and Scientific Research; also to this Ministry there now falls the care of the seven administrative units of the Indian Museum. Turning to the Institute itself, Dr. Hora discussed the publishing of original papers in the Institute's *Proceedings*, forty-four of the fifty-six submitted during 1951 having been published. The delay at present is seven to nine months, but by various means, including the printing of routine business in a new regular journal, the *Bulletin*, and in the Institute's "Year Book", it is hoped to find more space in the *Proceedings* for original work and at the same time to reduce the delay to not more than six months. As regards the quality of the English in the papers submitted, Dr. Hora pointed out that the standard is noticeably deteriorating, and he suggested that this fact should be borne in mind by the Government when formulating any plans about the place of the English language in its educational curricula. Dr. Hora did not flinch from making other critical comments. Thus, he said that he was disturbed at the apathy shown towards the activities of the Institute, even by its Fellows, and he went on to indicate that this is but one facet of a general failure by Indians to appreciate the merits of their country's scientists, as shown by the relatively poor salaries paid to those working in academic circles and also by the tendency to employ foreign scientific advisers in preference to local talent. In conclusion, Dr. Hora discussed the stepping-up of the biological sciences in India, and in this connexion the Institute has decided to recommend that departments for the special study of certain subjects should be established as follows: a marine biological station at Bombay; a central freshwater biological station at Mettur, Madras State; animal genetics at a cancer research centre in Bombay, a cytogenetics research wing at the University of Calcutta and a cytochemistry research wing at the University of Mysore; and plant genetics at the Indian Agricultural Research Institute, Delhi.

## Electron Microscopy of Plant Cilia

Further observations on the structure of plant cilia, by a combination of visual and electron microscopy, are given by I. Manton, B. Clarke, A. D. Greenwood and E. A. Flint in the current issue of the *Journal of Experimental Botany* (3, No. 8, 204; 1952). The cilia of zoospores of *Saprolegnia ferax, Chlorosaccus ulvaceus, Allomyces arbuscula* and *Olpidium brassicæ* are illustrated by some excellent photographs at magnifications ranging from × 2,000 (visual light under an oil immersion objective) to × 20,000 (electron micrograph). The flagella of these micro-organisms (three fungi and a yellow-green alga) showed eleven component strands, these usually being clearly differentiated into a central pair and nine others. These strands are observable in specimens which are undergoing fibrillar disintegration. Similar strand numbers have also been observed in ferns and in green and brown algæ. Stained and unstained specimens of *Saprolegnia* and *Chlorosaccus* have been closely compared in the electron microscope and the nature of the artefacts produced by staining investigated. Visual and electron micrograph records of one and the same stained cell have also been compared. Observation of the very distinctive but closely comparable flagellar character in brown algæ, yellow-green algæ and certain fungal and flagellate groups has led the authors to the conclusion that these groups are phyletically more nearly related to each other than they are to other groups, for example, green algæ (see also p. 280 of this issue of *Nature*).

## General Principles of University Research

In *Research for Industry* (4, No. 5; July 1952), the news bulletin of Stanford Research Institute, Dean Ernest R. Hilgard, of the Graduate Division of Stanford University, writing on "Fundamental and Applied Research in relation to the University", lays down three criteria for the choice of possible research projects by a university, including research grants or contracts offered by industry or government. First, the project should be in line with the professor's special interest and training; second, it should preferably be of a kind to make good use of the students and to provide them with a rounded training in research; third, it should normally lead to scholarly publication. These criteria do not exclude applied research, since it can meet these standards provided the inquiries are conducted in the true scientific spirit. Examining the kinds of research which normally should be less favoured by a university, Dean Hilgard lays down four further criteria. First, projects serving the immediate aims of industry or government but lying outside the scholarly interests of the staff and not in the direction of intended development; second, those requiring a pace of development best served by non-teaching scientists and full-time technicians; third, specialized projects requiring a staff so large as to disturb the equilibrium of the university; and fourth, research which requires excessive travel away from the university.

## Latin-American Course in São Paulo on Radio-isotope Methodology

A course on radioisotope methodology, the first of its kind ever to be held in Latin America, has been organized by the Faculty of Medicine of the University of São Paulo, Brazil, under the direction of Prof. A. Wormall, who has been temporarily seconded from the Department of Biochemistry and Chemistry, St. Bartholomew's Hospital Medical College, London, assisted by Dr. Tede Eston, Dr. Veronica Rapp de Eston, Prof. P. B. Smith and Miss Constancia Pagano, of São Paulo. The course, which started on January 14 and is a full-time one, lasting for six weeks, consists of two whole days of practical work each week together with theoretical lectures on the experiments to be made; in addition, four theoretical lectures are being given weekly and seminars held in connexion with the laboratory work. Those taking the course are graduates in science or medicine, and thirty men and women are at present participating, nineteen being from Brazil and eleven being holders of Unesco fellowships from other Latin-American countries; the limitation in numbers is due to the difficulties of accommodating the practical work, but there is no restriction on the numbers who may attend the lectures, and, in fact, four others are doing so. Most of the participants hold responsible positions in universities, research institutions or hospitals, and it is hoped that the course will enable them to make profitable use of radioactive isotopes for research and for clinical medicine. Further details can be obtained from the Laboratório de Isótopos, Faculdade de Medicina, Caixa Postal 2921, São Paulo, or the Divisão de Difusão Cultural, Reitoria da Universidade de São Paulo, rua Helvetia 49 a 55, São Paulo.

## Physical Society's Annual Exhibition

The thirty-seventh annual exhibition of scientific instruments and apparatus arranged by the Physical Society will be held during April 13–17 in the Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7. A return has been made to the practice of former years of placing the whole of the exhibition in the main buildings of the College (except for one heavy exhibit housed in the Mathematics Department of the Huxley Building, Exhibition Road, for which tickets of entry will not be required. Three discourses, each lasting approximately forty-five minutes, will be given at 6.45 p.m. in the Large Chemistry Lecture Theatre as follows: April 14, Dr. E. C. Bullard (National Physical Laboratory), "Seismic Study of Ocean Basins"; April 15, Dr. L. A. Jordan (Paint Research Station), "Particles, Pellicles; Pigments, Paints and Physics"; April 16, Prof. W. V. Mayneord (Department of Physics, Royal Cancer Hospital), "Scintillation Counting and its Medical Applications". A handbook giving details of the exhibits will be published early in March and will be available at the exhibition or ordered from the Physical Society (price 6*s*., or

7*s.* 3*d.* by post). The exhibition will be open at the following times: April 13, 10.30 a.m.–8 p.m. (Fellows and Press only, 10.30 a.m.–2 p.m.); April 14–16, 10 a.m.–8 p.m.; April 17, 10 a.m.–5 p.m. Application for tickets, which are of various types, available for part or all of these times, should be made as soon as possible to the Exhibition Secretary, Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7, from whom all further particulars can be obtained.

### Electronic Instruments in Atomic Energy: Course at Harwell

A specialized course on the design, use and maintenance of electronic instruments used in nuclear physics, radiochemistry and in work with radioisotopes will be held at the Isotope School of the Atomic Energy Research Establishment, Harwell, during March 16–20. The course will be limited to twelve people who are physicists or electronic engineers holding a degree or equivalent qualification, and will include lectures and practical work on counters, D.C. and pulse amplifiers, coincidence units, scalers and rate-meters. The instructional staff will be drawn from the Atomic Energy Research Establishment, but the Isotope School is outside the security fence and the subject-matter will be entirely unclassified. The fee for the course is 12 guineas, and living accommodation (at Buckland House, near Faringdon, which is one of the senior staff hostels of the Establishment), transport and morning and evening meals will be provided at a charge of 7 guineas. Application forms can be obtained from the Electronics Division, A.E.R.E., Harwell, near Didcot, Berks.

### Royal Society Lectures for 1953

Royal Society Lectures for 1953 will be delivered as follows: Croonian Lecture, on June 11, by Sir Ronald Fisher, professor of genetics, University of Cambridge; Bakerian Lecture, on May 7, by Prof. N. F. Mott, professor of physics and director of H. H. Wills Physics Laboratory, University of Bristol; Ferrier Lecture, on December 10, by Dr. F. M. R. Walshe, consulting physician to University College Hospital and to the National Hospital for Nervous Diseases; Wilkins Lecture, on March 5, by Sir Harold Hartley; Leeuwenhoek Lecture, on November 5, by Dr. K. M. Smith, director of the Plant Virus Research Unit (Agricultural Research Council), Molteno Institute, University of Cambridge.

### Announcements

The Council of the Royal Society has appointed Sir James Chadwick as the Rutherford Lecturer for 1953; he will deliver the Lecture at McGill University, Montreal, in the autumn. This is the second Rutherford Lecture to be given under the terms of the Rutherford Memorial Fund, the first having been delivered last year in New Zealand by Sir John Cockcroft.

The Guthrie Lecture of the Physical Society, which is given annually in memory of the founder of the Society, will be delivered on March 13 in the Lecture Theatre of the Science Museum, Exhibition Road, London, S.W.7, at 5 p.m., by Prof. M. Born, who will speak on "The Conceptual Situation in Physics and its Prospects of Development".

A Centenary Lecture of the Chemical Society will be given by Prof. A. Tiselius, of Uppsala University, at 7.30 p.m. on February 26 in the Lecture Theatre of the Royal Institution, Albemarle Street, London, W.1. The subject of the Lecture will be "Some Applications of the Separation of Large Molecules and Colloidal Particles".

A Centenary Exhibition of prints from the Royal Photographic Society's Permanent Collection and photographic apparatus collected by the Society and the Science Museum has been arranged at the Science Museum, Exhibition Road, London, S.W.7, and in the Society's House, at 16 Princes Gate, London, S.W.7. The Exhibition will be open from February 17 until March 28.

At the general monthly meeting of the members of the Royal Institution, held on February 2, Mr. Stanley Robson was elected secretary to fill the vacancy caused by the resignation of Prof. A. O. Rankine.

Mr. A. B. Duncan, chairman of the finance committee and a member of the Scottish committee of the Nature Conservancy, has been appointed chairman of the Conservancy in succession to Sir Arthur Tansley.

Mr. M. W. Thring has been appointed an assistant director of research of the British Iron and Steel Research Association. He will continue as head of the Physics Department of the Association.

Mr. F. E. Bruce has been appointed to the University readership in public health engineering tenable at the Imperial College of Science and Technology, London. The degree of *D.Sc.* (Engineering) of the University of London has been conferred on Mr. Stanley Whitehead.

The third annual conference of the Ergonomics Research Society will be held in the Department of Human Anatomy, University of Oxford, during April 13–16, and will take the form of a symposium on "Human Performance: its Measurements and Limitations". The conference will be under the chairmanship of Prof. W. E. Le Gros Clark. A fee of 30*s.* is charged for those who are not members of the Society. Limited accommodation is available in Brasenose College. Enrolment forms (to be completed at the latest by March 31) and further information can be obtained from H. Murrell, Spinneys, Marlpit Lane, Headless Cross, near Redditch, Worcs.

A conference marking the twenty-fifth anniversary of the Sub-Committee on Dust Technology of the Verein Deutscher Ingenieure will be held in Essen during March 26–27. After an introduction by the chairman, Robert Meldau, a number of papers will be read, including one by Prof. P. Jordan (University of Hamburg) on the distribution of fine dust in new theories on world creation, another by Prof. Correns (University of Gottingen) on dust in the formation of sedimentary rocks, and seven other papers dealing with various aspects of dust technology.

The first Marjory Stephenson Memorial Lecture will be given by Dr. D. D. Woods at the Royal Institution, Albemarle Street, London, at 6 p.m. on April 13, his subject being "The Integration of Research on the Nutrition and Metabolism of Micro-organisms". The Lecture is open to the public. The Marjory Stephenson Memorial Fund is administered by the Society for General Microbiology, and the Lecture will be given during the sixteenth general meeting of the Society. Further details can be obtained from the general secretary of the Society, Dr. J. G. Davis, 52 London Road, Reading, Berks.

# HYDROBIOLOGY AND INLAND FISHERIES OF AFRICA

THE principle of the symposium as a means of taking stock and stimulating new work in science may be said to have a value which is in direct proportion to the isolation of the workers concerned. Thus symposia have special value in the more remote parts of the world where many workers are to-day striving towards common objectives in small institutes or organizations hundreds or even thousands of miles apart. A good example was the symposium on African hydrobiology and inland fisheries which was held during October 14–17, 1952, under the ægis of the Scientific Council for Africa South of the Sahara. It brought together more than forty workers in these subjects from sixteen different territories in Africa, including Belgian, French, Portuguese and British Colonies, the Union of South Africa and Southern Rhodesia. The site was Entebbe in Uganda, appropriate in that it is near the centre of Africa and is lapped on three sides by Africa's largest lake.

The symposium was opened by Sir Andrew Cohen, Governor of Uganda, in an erudite speech in French and English. He mentioned the progress in African scientific co-operation which is being achieved by the Commission for Technical Co-operation in Africa and by the Scientific Council for Africa South of the Sahara, and pointed to the importance of the development of fisheries in solving a major nutritional problem of Africa, particularly in a country like Uganda, which has more than its fair share of lakes and swamps. He referred particularly to the need for scientific background: "It is a commonplace," he said, "so great that it need not be repeated publicly, that one of the main keys to agricultural development lies in the knowledge of soils. In the development of fisheries the water is the soil, and yet we know too little about our waters".

The contributions and discussions inevitably covered a wide range, including comparison of the organizations in the various territories, information services, fish and fisheries of natural waters, fish farming, trout fisheries, hydrobiology in relation to disease, legislation, and the co-ordination of fishery interests with those of agriculture and other subjects in the use of Africa's meagre water supplies. From the Belgian Congo, C. Halain described the successful results of the campaign for establishing numerous fish farms in native areas, and Dr. A. F. de Bont described scientific results achieved in that connexion, these being compared with experience in fish farming contributed by Dr. D. Hey and Dr. S. S. du Plessis from South Africa, J. L. Lemasson and others from the French territories, H. C. Copley and Dr. V. van Someren from Kenya, O. E. Symes from Nigeria, and others. The fish farming industry of Africa is being built mainly on the numerous local species of *Tilapia*, and this led to discussion on the transportation of fish from one drainage basin or fish region to another. It was generally agreed that, while economic development cannot be held up, it is more important during the next few years to learn more about the local endemic species in their natural waters and under conditions of culture, than to distribute widely those few species which have already proved themselves useful under domestication.

Sessions devoted to natural waters included some important contributions on production biology from the East African Fishery Research Organization's laboratory at Jinja, which has now been in existence for several years. R. S. A. Beauchamp and G. R. Fish, for example, threw considerable light on the highly complex hydrology of Lake Victoria. Dr. J. Rzoska, from the University College of the Sudan, described hydrobiological researches on the White Nile, particularly the influence of the reservoir contained by the Gebel Aulyia barrage near Khartoum.

An academic note was sounded in discussions of the ecology of tropical swamps introduced by Prof. L. C. Beadle, of Makerere College, and on the biology of speciation in African lakes introduced by Dr. E. B. Worthington. This turned around the debatable problem of sympatric and allopatric speciation, which was argued particularly, by P. H. Greenwood from his studies of *Haplochromis* flocks in Lake Victoria, Miss R. Lowe on the associations of *Tilapia* species from Lake Nyasa and elsewhere, and Dr. G. S. Carter, who is spending a year at the Jinja Laboratory on sabbatical leave from Cambridge.

Much new information was brought to light on a variety of African fishes in relation to their environments, particularly those of economic importance and including the introduced species of trout in the highland areas. A feature of the meeting was an account of research on fish-eating birds and on the ecology and economic status of the crocodile by another visiting worker from Cambridge, Dr. H. B. Cott. His results promoted discussion on the policy which should be adopted by Governments in applying some control to the industry in crocodile skins, which in some waters may threaten the very existence of crocodiles. Whereas views were expressed that the crocodile is an animal which could well be dispensed with in areas of economic fisheries, particularly on account of the destruction which it causes to fishing nets, it was generally admitted that its influence on food chains is yet inadequately known and might sometimes be beneficial. For example, an experience was recounted from Madagascar that the destruction of crocodiles had been associated with an increase in the incidence of rabies: crocodiles no longer eliminated rabid dogs which were drinking.

Prof. J. Millot (of the Muséum d'Histoire Naturelle, Paris, and of Madagascar), who was chairman of the symposium, remarked in his concluding speech that the meeting as a whole had provided the opportunity for a thoroughly useful exchange of experience and views from a very wide region, and the contributions and discussions had achieved a high scientific standard. The fact that the hydrobiology of Africa is achieving a considerable importance and is less isolated than formerly is illustrated by the fact that no less than ten of the participants at this symposium expect to attend the Twelfth International Limnological Congress, to be opened during August at Cambridge. The language problem, which is so apt to impede international meetings, was solved by simultaneous interpretation at the symposium. A full record will appear as an official publication in due course. E. B. WORTHINGTON

# SIGNIFICANCE OF RACIAL DIFFERENCES

DR. G. M. MORANT'S informed and clearly reasoned pamphlet on "The Significance of Racial Differences"* makes an important contribution to the series of publications on the question of race published by the United Nations Educational, Scientific and Cultural Organization. Racial differences, their extent and their significance, are burning questions to-day when racial stresses are rampant. What has been established by a century of scientific inquiry should be more widely known, and the methods of approach to such questions more widely understood. "Popular views of the matter are still nebulous enough to be swayed by anyone who chooses, for his own ends, to spread 'racial' dogmas which cannot readily be proved true or false."

Racial differences, physical and mental, have indeed been a subject for literary discussion for two thousand years and more. But a fundamental weakness is that it has no agreed systematic method of considering such questions of group difference. The classes of evidence chosen for emphasis and the choice and interpretation of items in those classes are usually such as best fit some general theory of the writer's; they offer a wide field for bias and produce many contradictory conclusions. But certain tendencies are general: to regard as 'racial' many differences that are environmental or cultural; to reduce, for simpler thinking, the variety that every group exhibits to the uniformity of a single type; to endow that type with the more extreme and striking attributes of a few, rather than with those of the group as a whole; and to assume that groups which are markedly different in regard to some obvious physical attribute must have certain marked differences in mental make-up.

Scientific inquiry, on the other hand, whether into the physical, physiological or mental constitution of human groups, has the same agreed basic method of approach, which the author describes. By techniques of analysis which compare groups as a whole, it has established for many attributes (or 'characters'), especially physical, the actual extent of racial differences. "The ways in which men differ are of small account compared with the ways in which they are alike, but the former make up the class defining individual and group distinctions."

Though the physical differences between groups may often have little practical importance—apart from the influence on attitudes and intercourse of any that make very obvious distinctions between peoples—the results of the study of the physical characters have this advantage: that most characters of form, size or colour are mainly (and blood groups are believed to be entirely) determined by hereditary factors; whereas the outward manifestations of mental characters are determined to a considerable extent by experience and social environment. In both cases it is the hereditary, the racial, factors that are in question, and the ampler findings in regard to physical characters can throw light on the more complex question of the mental differences between racial groups.

Within all racial groups for which there are adequate records over the past seven thousand years, physical variation as recorded is of much the same order: rather less, as a rule, in the earlier series than the later, but not much; rather more in modern Europe than elsewhere, but with exceptions. There is considerable variation in group averages; but for very few 'continuous variables', apart from characters of colour and hair form, can groups be found the distributions of which do not overlap. Even in stature, and taking groups at opposite ends of the range, the tallest Congo pygmy is about as tall as the shortest Dinka; and in pairs of racial series selected at random about one in three would differ in average height by less than 4 cm. Dr. Morant, by a slip, says "about one in 130" (p. 32), a figure contradicted by the evidence of his distributions; also, in stating (p. 41) that no other measurement is known to differentiate racial populations as effectively as stature and cephalic index, he overlooks nose-breadth, which differentiates more effectively than either—hand-breadth probably too (*Man*, 50, No. 14). These errors do nothing to weaken his argument. For almost all metric characters, inter-racial variation is less than intra-racial, and the distributions for even the most divergent groups overlap widely, so that a large proportion of the individuals belonging to one could belong to either.

Valid comparisons between group averages for innate, hereditary, mental ability and disposition are difficult to make for racial groups whose mental experience is very different; but mental tests have at least shown a wide range of variation in any group tested, and—allowing for differences of background—wide overlap in group distributions. A rule found to apply to all forms of life is that variation within inter-breeding groups is associated with variation between such groups; and it is improbable that man's mental characters, unlike his physical, are an exception. "The general inference is that there are racial differences in mentality, although clear demonstration of them—regarding particular characters and particular pairs of populations—is not available yet". The differences are not likely to be all in favour of the same groups. Nor does it necessarily follow that a wide average difference in some physical trait is associated with a wide average difference in some mental trait. Also, the average mental differences may be small: existing evidence suggests "that group diversity tends to be less in degree for mental tests than for body measurements"—if less, not less significant.

Dr. Morant points out an aspect of group difference that, for mental characters, may make a distinction of importance. Two overlapping distributions of which the mean values are not far apart are yet likely to differ considerably in their relative frequencies of individuals having extreme values of the character. "There may be almost equal proportions of stupid, mediocre and able people in two populations; even so, exceptional ability may be found with a frequency of 1 in 1,000 in one group and with a frequency of 1 in 10,000 in the other. Having a larger proportion of exceptionally able members may be a factor which tells decisively in favour of a population in the course of centuries or milleniums." One might go further than does Dr. Morant in this informative and thoughtful pamphlet: at turning points in a nation's history it may tell decisively, though briefly, on its whole future course.

# NEW ZEALAND FOREST SERVICE

## REPORT FOR THE YEAR 1950–51

THERE is a breezy directness about the annual forestry reports of New Zealand* which should invite public attention. Yet under the heading "Purpose of Annual Report", the Director of Forestry writes: "Practically without exception the annual reports of the Director of Forestry have been used consistently since 1934 to review forest policy. There have been few if any facets of policy that have not been reviewed on numerous occasions. Primarily, these reviews have been intended to inform Parliament on the Department's discharge of its responsibilities under the various Forest Acts and their amendments. Equally, they have been directed at the public in the expectation that, the annual reports being public documents freely available both to the press and to interested bodies, the public would be adequately informed of the evolution of forest policy. That expectation has proved illusory. A month seldom passes without there being some definite evidence that policy reviews are either not consulted or completely ignored. Clearly, annual reports are insufficient in themselves to promulgate forest policy". In forestry matters the Director is not alone in this discovery.

One of the chief troubles in New Zealand, as elsewhere in both the Old and New Worlds, is fire damage. The Director contrasts New Zealand with Scandinavia where, he says, fire protection work is much less costly because the people have become forest-minded. This is true of the peoples of other parts of Western Europe, and we have yet to acquire this attribute in Great Britain. In New Zealand, on the other hand, says the report, there is a tradition of land-clearing to make farms, and most of the people of the cities are out of touch with forests and forestry. In order to improve fire publicity, the campaign against fire is now to be merged in public relations affairs.

In the annual report for 1948–49, under forest policy, it was announced that the decision had been taken by the Government to establish a saw mill and a pulp and paper mill at Murupara on the Rangitaiki River in the Rotorua Forest Conservancy —the first of its type in the Dominion (see *Nature*, 165, 966; 1950). There was afterwards considerable hesitancy in embarking on this great scheme to exploit the extensive forest in question. The proposed development is of high interest in its novel departure. Later in the year the Government finally took the momentous decision to proceed with the project, and in order that the resources of this great forest may be exploited without further delay, the Government effected, during the 1950 session, the passage of legislation empowering the construction of the Edgecombe–Murupara Railway and granted financial authority for the work.

On the subject of soil conservation, about which so much is talked and written nowadays, the report correctly says: "The joining of soil conservation with river control has served to cloud the fundamental issue that in the final analysis both soil and water problems are essentially land and not engineering problems". The example is given of the failure of the British groundnuts scheme, and allusion is made to serious fears that all is not well with the much-advertised Tennessee Valley Authority scheme. As is well known, the necessary protection of the head-waters of the various waters upon which the scheme is based was ignored.

It is estimated that 80 per cent of the erosion and flooding troubles of New Zealand would ultimately disappear if land and forest fires could be entirely eliminated; a further 15 per cent would be rectified if overgrazing by wild life and by farm animals could be stopped, and other better farming practices universally instituted. E. P. STEBBING

# METEOROLOGICAL OFFICE

## REPORT FOR THE YEAR 1951–52

THE principal feature of the report of the Director of the Meteorological Office for the year ending March 31, 1952*, is the attention which is being devoted to the study of the atmosphere in the region between about 30,000 and 50,000 ft. in height—roughly the top of the troposphere and the lowest part of the stratosphere. This region is particularly important because jet aircraft fly in it at a fuel consumption which for the distance covered is less than at lower levels. The winds there are sometimes very strong, having been known to exceed 150 knots (about 280 km./hr.), and the air is sometimes bumpy for no visible cause (such as thunderclouds) which would give warning to pilots. The forecasting of wind-speed and -direction and turbulence in this region is an important meteorological problem. The increased attention given to the upper atmosphere is partly shown by the formation during the year of a new Branch of the Office for detailed study of the Climatology of the Upper Air; previously, this work had been the function of a section of the Overseas Climatology Branch. Research into the forecasting of winds at high levels has continued during the year, and analysis of occasions of clear-air turbulence has confirmed earlier indications of an association between turbulence and the presence of marked variation in wind-speed in the vertical and horizontal directions. The work on turbulence included observations by the Meteorological Research Flight of the behaviour of smoke trails emitted by aircraft.

The forecasting of radiation fog is a major meteorological problem of importance to all forms of transport. A special organization was set up at Cardington (Bedford) to examine the development of fog. The work includes observations with the aid of instruments which can be carried by kite-balloon to more than 2,000 ft. Experimental forecasts for four days ahead were prepared twice weekly in the Forecast Research Division. A measure of success was attained; but the reliability of the forecasts was not sufficient to enable a decision to be made to devote additional staff to this work. Among other subjects of research described in the report are the study of cloud structure by radar, icing on aircraft, and the development of instruments, such as the radar theodolite, for measuring upper winds.

The meteorological services provided for the Royal Air Force and Army, civil aviation, the general public and industry continued to expand. A large meteorological exhibition was set up in the Dome of Discovery of the Festival of Britain Exhibition in

* Annual Report of the Director of the Meteorological Office presented by the Meteorological Committee to the Secretary of State for Air for the Year April 1, 1951, to March 31, 1952. (M.O. 562.) Pp. 56. (London: H.M.S.O., 1952.) 2s. net.

London. The exhibition included a weather-forecasting unit at which a special souvenir weather report and forecast was compiled, and more than 150,000 copies were sold to visitors. The overall strength of the Office staff decreased from 2,601 to 2,589 during the year; but the scientific officer class increased from 160 to 165. A number of university students, mainly of physics and mathematics, worked in the research centres of the Office during vacations.

## DRYING OF HIDES AND SKINS

It is twenty years since experimental work in Kenya yielded results which established principles for the correct drying of hides; the experience gained since that time has now been described by J. R. Furlong, principal of the Colonial Products Advisory Bureau (Plant and Animal) (*Colonial Plant and Animal Products*, 2, No. 4; 1951).

To obtain the best possible leather from a hide, it is desirable to proceed to the tanning operations without reducing the hide to a dry state. Many countries, however, have insufficient native hides for their needs, and it is necessary to bring supplies from overseas or long distances to the tanneries. The distance which green or lightly salted hides can safely travel without damage caused by putrefaction is very limited, and it is essential to submit the hides to some process of curing in order that they may be transported and stored without deterioration. The curing may consist of salting the hide and transporting it in a wet-salted condition—an expensive method applicable to the best qualities of hides, or the material, after salting, may be dried out and sent to the market in a dry-salted condition. In many countries, however, salt is scarce and the use of the imported material would be too costly. Recourse is therefore made to the procedure of air-drying as a method of preservation. This is practised in many hot countries, particularly in the African continent. Dry hides represent a large proportion of the production of the entire output of such countries as Nigeria, East Africa, South Africa, the Sudan and Abyssinia, while India and South America are also large producers of dry hides.

Dry hides are an important class of raw material for the tanneries of the world to-day. In the decade before the War many tanners had developed a technique for producing leather of the highest quality from this class of hides, and during the War a still larger number of tanners in the United Kingdom were forced to use Colonial dry hides for the first time. While Continental tanneries had always handled Colonial hides, it is the great advance which has been made in this connexion in the United Kingdom, as a result of war-time experience, that is of significance. Tanners have learnt how to obtain good results, and it is to Colonial sources that English tanneries now look for increasing supplies of their raw materials.

The article describes methods which are now being used in the suspension-drying of cattle, goat and sheep skins, and emphasizes that the old method of drying hides and skins on the ground is liable to cause serious damage, and should never be employed. Drying hides and skins on the ground should be prohibited in areas where the improved processes of suspension-drying are practicable.

---

## HANDLING OF RADIOACTIVE AND TOXIC SUBSTANCES

An edited report of the proceedings of the symposium on the handling of radioactive and toxic substances, which was organized by the Chemistry Division of the Atomic Energy Research Establishment, Harwell, and which was held in two sessions on September 10–11 and 13–14, 1951, at Buckland House, near Faringdon, Berks, has recently been issued*. Sixty-four representatives from the chemical industry, universities, hospitals, government research establishments and the atomic energy projects of Western European countries attended. A list of the various representatives and their respective organizations is included in the report. The chairman, Dr. R. Hurst, welcomed the representatives, and mentioned that the original suggestion to hold such a symposium came from Dr. R. Spence, the head of the Chemistry Division at Harwell.

The contributed papers and subsequent discussion centred around three topics: the use of glove boxes, remote control of chemical operations and laboratory housekeeping and decontamination. Dr. Hurst, who spoke first, described the various improvements and requirements in the design of glove boxes which experience of their use at Harwell has indicated. He stated that glove boxes provide the simplest means of confining a chemical operation so as to prevent the spread of radioactivity, or to exclude oxygen, dust or harmful organisms. Suitable gloves developed for use in these boxes were described and shown. The use of heat-sealed polyvinylchloride bags for the transfer of active material or apparatus into or out of glove boxes was recommended. Mr. J. G. Bell then gave details of a glove box design with double-wall protection for work on alpha-active materials which require a protective atmosphere, and Mr. W. G. Busbridge discussed the requirements of filters for use with glove boxes. The disadvantages of wool-resin filters were pointed out, and a new type of filter employing a mechanical filter of wool and asbestos was briefly described.

On the subject of remote control of chemical operations, the discussion centred on two general methods: systems of tongs, manipulators and periscopes, by which conventional apparatus can be used by an extension of the hands; and systems by which liquids can be transferred, precipitates removed and similar operations conducted by vacuum-lifting or by pumping from vessel to vessel. In this section papers were read by J. Dean and A. B. Ritchie, G. B. Cook, G. N. Walton, G. Wortley, and Dr. W. J. Arrol. Finally, Dr. G. L. Miles reviewed the general problem of laboratory management in radiochemical work, the housekeeping techniques which are essential to prevent and restrict the spread of radioactivity and to keep the working-space clean and free from contamination. It was emphasized that hoods, glove boxes and apparatus should have hard smooth surfaces, that detergents are generally satisfactory as decontaminants and that certain radioisotopes may need special treatment. Recommendations on the disposal of active waste were also made.

The report makes interesting reading and is amply illustrated by photographs and diagrams.

# HISTOCHEMISTRY OF SUCCINIC DEHYDROGENASE

By Dr. H. A. MALATY and Dr. G. H. BOURNE
Department of Histology, London Hospital Medical College, London, E.1

KUHN and Jerchel[1] synthesized various substituted tetrazolium salts and showed that their aqueous solutions stained living tissues (for example, yeast and bacteria). Various other workers confirmed this (see Smith, ref. 2). Tetrazolium is a compound which becomes coloured when it is reduced, and this suggested that the effect of its solutions in colouring living tissues may be due to the effect of reducing substances or to dehydrogenases present in them. Jerchel and Kohle[3] showed that it was possible for these tetrazolium compounds to act as hydrogen acceptors for some pyridine-nucleotide dehydrogenases. Tynen and Underhill[4] first used tetrazolium (triphenyl tetrazolium chloride) as a histological reagent, demonstrating subcutaneous fat with it. They found that injection of a 1 per cent aqueous solution of triphenyl tetrazolium chloride into mice stained neutral fat a bright orange-red in 5–10 min. They suggested that the fatty tissue caused reduction of the tetrazolium to a formazan pigment. Black and Kleiner[5] also used the same compound for measuring the respiration of tissue slices, and Kun and Abood[6] appear to have been the first to use it specifically for the estimation of succinic dehydrogenase activity.

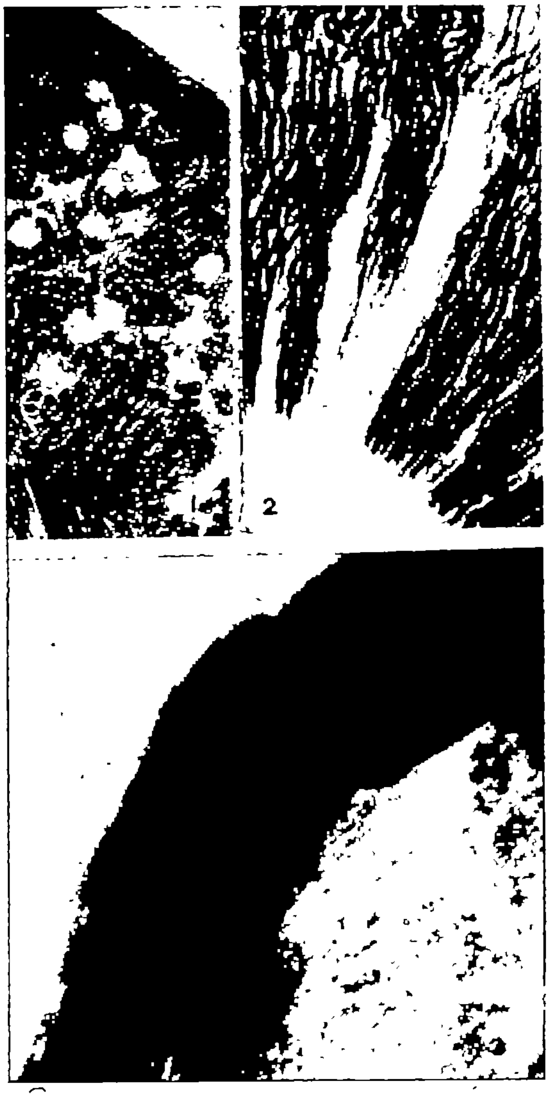
Rutenberg, Gofstein and Seligman[7] described the synthesis of blue tetrazolium and its use for estimating succinic dehydrogenase activity in tissue homogenates. Afterwards, Seligman and Rutenberg[8] showed that this enzyme could be demonstrated histochemically using blue tetrazolium. An analysis of the specificity of tetrazolium compounds for the histochemical detection of succinic dehydrogenase has been given recently by Shelton and Schneider[9].

The rationale of the technique is as follows. Blue tetrazolium is ditetrazolium chloride and is pale yellow in aqueous solution; it is a hydrogen acceptor and becomes reduced to a blue water-insoluble pigment (diformazan). Fresh-frozen sections are placed in a substrate[8] containing 1 part of water, 1 part of 0·2 *M* sodium succinate, 1 part of 0·1 *M* phosphate buffer (*p*H 7·6) and 1 mgm. of blue tetrazolium per ml. The reaction develops in about two hours. We have found that by this time the maximum colour has developed, and that even leaving the sections over-night does not intensify the colour further. The succinic dehydrogenase in the tissues is, of course, responsible for the splitting of hydrogen from the succinate, and this reduces the tetrazolium to diformazan which, being insoluble, is precipitated at the site of enzyme activity.

We have investigated this reaction in guinea pig, rabbit, mouse and rat tissues. Technical points which we have found affecting the reaction are as follows.

(1) *Method of killing the animal.* Some animals were killed by anaesthetizing with chloroform, some by ether, some by 'Nembutal' injection and some by a blow on the head. In animals killed by the use of anaesthetics, it was difficult to obtain a satisfactory reaction for the enzyme, particularly with the liver and cardiac muscle. The reaction in kidney, brain and nerve appeared to be unaffected by the method of killing the animal except in the case of the rabbit, when it was almost impossible to obtain a result from any of the tissues after anaesthesia. A blow on the head appeared to be the most satisfactory way of killing the animal.

(2) *Thickness of sections.* Seligman and Rutenberg found that sections of 8 μ or less gave no reaction, and that sections 20 μ thick gave optimum results even though about one section in five gave no result. Presumably these negatives are due to oxidation of the diformazan, since a greater number of positive sections is obtained if oxygen is excluded from the system. Seligman and Rutenberg found that thicker sections than this were unsatisfactory. Shelton and Schneider agree with Seligman and Rutenberg in this respect. We have, however, obtained poor results with 20-μ sections, but have been able to obtain excellent and consistent results with sections of 50–100 μ.



Succinic dehy rogenase preparations
(1) Kidney (rabbit); note positive reaction in convoluted tubules; negative reaction in glomeruli. × 35
(2) Kidney (rabbit); note positive reaction in Henle's loops; negative reaction in lower collecting tubules. × 35
(3) Striated muscle (rabbit); note positive reaction given by rows of sarcosomes between muscle fibrils. × 1,000

(3) *Fixation.* We obtained our best results from sections which were not treated with any fixative—even acetone proved unsatisfactory. Seligman and Rutenberg hardened their sections after incubation by treatment with 10 per cent formalin for 30 min. The sections should be mounted in glycerine jelly or in Apathy's medium.

(4) *Freshness of buffer.* We found that it was essential to use freshly prepared buffer.

(5) *Sectioning the tissue.* We found that freezing the tissue in a drop of water for sectioning was less satisfactory than freezing it on its own and dropping the sections directly into the substrate solution.

Shelton and Schneider tested four tetrazolium compounds as indicators of dehydrogenase activity. These were neo-tetrazolium, blue tetrazolium, tetrazolium violet and 2,3,5-triphenyltetrazolium chloride. The first two of these were found to be satisfactory, the last two unsatisfactory. Neo-tetrazolium gave the most rapid reaction. These authors found that fresh tissues had some endogenous ability of reducing tetrazolium salts; but that this ability was for some unknown reason lost when the tissues were frozen. They found that crystalline lactic and alcohol dehydrogenases did not reduce tetrazolium salts in the presence of their substrates, but that purified xanthic oxidase and diphosphopyridine nucleotide–cytochrome c-reductase were able to reduce these salts. Nevertheless, under the conditions of the histochemical test when carried out on frozen sections, they consider the reaction reasonably specific for succinic dehydrogenase, although they do not deny that mediation by other enzymes may be involved. In our own experiments no reaction was obtained when the succinate in the reaction mixture was replaced by malate, fumarate, citrate or cysteine.

In the animals we have examined, we have investigated the distribution of the reaction in peripheral nerve, liver, heart muscle, skeletal muscle, kidney and cerebellum.

Like Seligman and Rutenberg, we found the kidney very rich in this enzyme, but we did not, as they did, find cardiac muscle to have greater activity: we found it to have less. We found kidney to have the highest activity, then cardiac muscle, skeletal muscle, cerebellum, liver and peripheral nerve. Our results with kidney agree with those of previous authors in that we found the cortex of the kidney very rich in activity but the medulla almost completely negative; in other words, as with alkaline phosphatase, the enzyme was localized in the metabolically active part of the kidney (the convoluted tubules and Henle's loops) and only in the beginning of the collecting tubules. Glomeruli were almost completely negative. Like Shelton and Schneider, we found little evidence of diffusion in our preparations, when the blue granular reaction was given. We were not able, however, to decide upon the significance of the diffuse purple reaction given by some tissues which Seligman and Rutenberg find accompanies regions of low activity.

In cerebellar tissue, the outer (molecular) layer of the cortex showed this diffuse coloration, which increased in intensity and reached its maximum colour at the junction with the inner (granular) layer. The Purkinje cells were of the same intensity as the surrounding tissue. In the granule layer the cells and processes stained a diffuse purple colour (the white matter of the cerebellum was completely negative), but in addition the cells contained blue granules. In some cases these were evenly distributed in the cytoplasm and in some cells there was a juxta-nuclear or peri-nuclear aggregation of granules which linked together to give a network-like appearance resembling the Golgi apparatus.

The liver, in addition to a diffuse purple background, showed blue granules in the cells and in some cells bright blue rods and filaments.

Peripheral nerve also gave a diffuse purple reaction, and faint blue granules could be seen in places; but it was not possible to be certain whether these granules were between or within the nerve fibres. The cells of the perineurium showed blue granules in many places.

The intra-cellular distribution of succinic dehydrogenase is of considerable interest since differential centrifugation studies have shown that the large-granule fraction (presumably composed chiefly of mitochondria) contains practically all the succinic dehydrogenase activity of the tissue. Shelton and Schneider found that the large-granule fraction reduced tetrazolium salts when incubated with them. They found that the mitochondria and masses of reduced tetrazolium (formazan) crystals formed a *matte*, but they were not able to see whether individual mitochondria were stained. These results support the view that considerable succinic dehydrogenase is localized in the mitochondrial fraction; and it suggests that a good deal of activity is localized in, or possibly adsorbed on, the surface of the mitochondria, but gives no information whether any further activity is present inside the mitochondria.

Our preparations of kidney and liver showed a granular formation in many of the cells which was identical with mitochondria; but much more striking were our preparations of skeletal muscle. Here we found closely packed chains of granules between the muscle fibrils which gave an intense positive reaction. There is no doubt that these granules, from their form and localization, are sarcosomes—elements which are known to be mitochondrial in origin and to contain enzymes identical with those present in the mitochondria of liver cells. We have found a similar localization of activity in the sarcosomes of heart muscle. Seligman and Rutenberg publish a photograph of heart muscle which also shows this; but they simply refer to it as granular and homogeneous deposits in the myocardial cells. Parts of our preparations (liver, kidney and muscle) show large amorphous granules and some show structures which are strikingly mitochondrial in shape and form. High-power observation of the amorphous granules suggests that these may represent mitochondria, on the surface of which a mass of formazan crystals has accumulated. The same thing occurs in a few of the sarcosomes of muscle. On the other hand, some mitochondrial-like bodies and most sarcosomes seem to be stained an intense dark blue with no obvious signs of formazan crystals on the surface. This appears to suggest that the enzyme causing this reduction is present within the mitochondria, although it may, of course, be associated with the mitochondrial membrane.

One of the criticisms of the work on the localization of respiratory enzymes in mitochondria as demonstrated by the technique of differential centrifugation is that the enzymes may be adsorbed on to the mitochondria from the homogenate; however, the papers of Seligman and Rutenberg and of Shelton and Schneider, together with the results of the present study, present strong evidence that succinic dehydrogenase activity is closely associated with the mitochondria in the intact cell.

Since this paper was written, an extensive study of the histochemical reaction for succinic dehydrogenase has been published by Padykula[10]. In general, we agree with her results. She found also that, if sections were incubated in an atmosphere of nitrogen, much more consistent results were obtained.

We are indebted to Prof. E. W. Dempsey, of Washington University, St. Louis, for a supply of blue tetrazolium which was used in this work; also to Drs. Schneider and Shelton, of the National Institutes of Health, for a supply of neo-tetrazolium with which some of this work was confirmed.

# TRAVELLING-WAVE LINEAR ACCELERATOR FOR X-RAY THERAPY

By C. W. MILLER

Research Department, Metropolitan-Vickers Electrical Co., Ltd., Manchester 17

DURING the past three years a linear accelerator having a design energy of 10 MeV. has been undergoing development for the Medical Research Council. The work has been performed by the Metropolitan-Vickers Electrical Co., Ltd., in conjunction with the Atomic Energy Research Establishment, Harwell, and the Medical Research Council. The machine, which is the first of its kind to be built specifically for X-ray therapy, has now completed its performance tests and has been installed at the Hammersmith Hospital, London.

Brief descriptions of the construction of this machine have already appeared[1,2], and the design of the accelerating tube itself follows closely the theory published by members of the linear accelerator team from Harwell[3,4], much of the computation being carried out by them. The corrugated waveguide is 3 m. in length, has $a/\lambda = 0{\cdot}168$ and operates at a free-space wave-length of 10·0 cm. The corrugation pitch is 1 cm. over the first 40 cm., and 2 cm. over the remaining length of guide. The ratio of phase velocity to that of light is approximately 0·4 at the input end, increasing to 0·992 at 1 m. along its length and thereafter remaining constant at 0·996. Electrons are injected into the accelerator from a gun operating at 45–50 kV. The electron dynamics require a power flux of some 3·6 MW., and, as the radio-frequency power source provides pulses of 2 μsec. duration and 2 MW. peak power, feedback as described by Harvie and Mullett[5] is used.

In much of the experimental work the machine was operated with a target mounted directly on the end of the accelerating tube. For clinical use an X-ray head is fitted in which the electron beam is deflected through a right-angle before hitting the target. This head can be rotated about the axis of the accelerator to change the direction of the X-ray beam.

The first length of corrugated waveguide was manufactured to dimensions calculated from the theory given by Walkinshaw[4]. Low-power measurements on this section of guide showed that the phase velocity at the design frequency was in error by some 5 per cent. Dimensions for a second length of guide were determined by scaling from the experimental results, and this new guide was found to have the required velocity characteristics. The discrepancy between theory and the experimental results has been found, and Walkinshaw and Bell have, in as yet unpublished work, derived an alternative method which not only avoids this error but also gives more rapid convergence.

The accelerator was operated for the first time in December 1950 and has from the first given a very large X-ray output. Measurements have been made of beam current and power, electron energy and X-ray output, and the variation of these quantities as functions of the operating conditions, such as radio-frequency power and frequency, focusing field and electron injection current, has been investigated. By modification of sections of the guide, the performance of the machine with several different phases of electron bunching was determined. The variations obtained in these tests were qualitatively in agreement with theory, and from the curves obtained it was possible to determine the best arrangement for installation. For clinical operation, not only is it desirable that high current and energy be provided but also that, owing to the change in direction of the electron beam in the X-ray head, a narrow spectrum of electron energy is required, and variation of energy with input power and frequency must be minimized. Typical performance curves are shown in Figs. 1 and 2. By running at a somewhat higher power-level and increasing the recurrence-rate beyond the nominal maximum of 500 pulses/sec., greater outputs can be obtained. At 600 pulses/sec. the X-ray output may be increased to 1,000 r./min. at 1 m., while at 700 pulses/sec. an output of 1,250 r./min. has been achieved. Short-term stability of the equipment is good, while long-term stability is ensured by means of a servo-operated phase shifter[6] in the waveguide feedback circuit, to correct for frequency drift and temperature changes of the corrugated waveguide. X-ray output stabilization at a preset value is obtained by variation of the gun-filament current. The width of the X-ray beam produced, using a thick gold target, has been found to be 24·5° at half intensity. A beam-flattening filter is incorporated to give uniform intensity at 1 m. over a circle 26 cm. in diameter. The treatment area, normally rectangular, can be adjusted by means of sliding diaphragms down to a minimum of 3 cm. square, and for circular fields special diaphragms may be inserted. The diameter of the electron beam is approximately 3 mm., and the consequent small spot-size and stability of its position ensures an adequately small penumbra. In clinical use it is intended to operate at dose-rates up to 200 r./min. at 1 m. from the target, a normal single treatment thus requiring an exposure of the order of two minutes. This output is considerably below the maximum shown in Fig. 2 and allows for stabilization and losses in the X-ray head, including the beam-flattening filter.

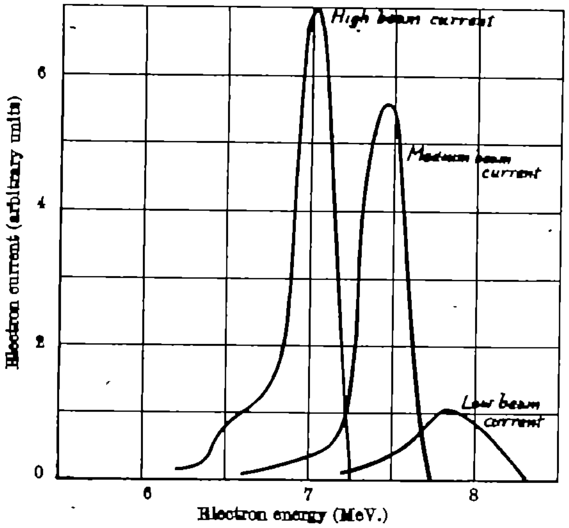

Fig. 1. Typical performance curves of linear accelerator, showing electron energy spectra

The conversion from electron current to X-ray output is 18·2 r./min./μA. at 1 m. for an energy of 8 MeV., while the exponent for the variation of this figure with energy is 2·87.

In general, the performance of the equipment has shown a close agreement with theory, with the exception that the electron energy is lower than was expected. An explanation which reconciles theory and measurement has been found as follows. In the design the relationship between accelerating field and power flux has been evaluated using the theory given by Walkinshaw[4]. In this the fields in the corrugated guide ($E_\rho$, $H_\varphi$ and $E_z$) are given as an expansion in Bessel functions with coefficients $A_0$, $A_1$, etc. It is only the term with coefficient $A_0$ in the expansion for $E_z$ which gives acceleration. Power flux is determined by the integration of the Poynting vector, $E_\rho \times H_\varphi$, and this, of course, leads to a further expansion. Following Walkinshaw, it had been assumed that only the term from the product of the two terms with coefficients $A_0$ was of significance, and from this assumption the relationship between the accelerating field and power flux was obtained. Further investigation shows that the assumption was not justified and that an appreciable part of the power flow is attributable to other terms in the expansion. The exact evaluation becomes difficult and has only been carried far enough to show that the effect can qualitatively explain the low energy. In order to obtain a quantitative relationship, measurements were made using a perturbation method based on the work of Maier[7] and Hansen and Post[8]. In these experiments the resonant frequency of a cavity constructed from a short length of corrugated guide is changed slightly by means of a metallic bead or piston. The fractional change in frequency together with the group velocity, determined by dispersion measurements, enables the relationship between the axial field and power flux to be calculated. Values obtained in this way confirm that the expected energy of the accelerator should have been approximately 8 MeV.

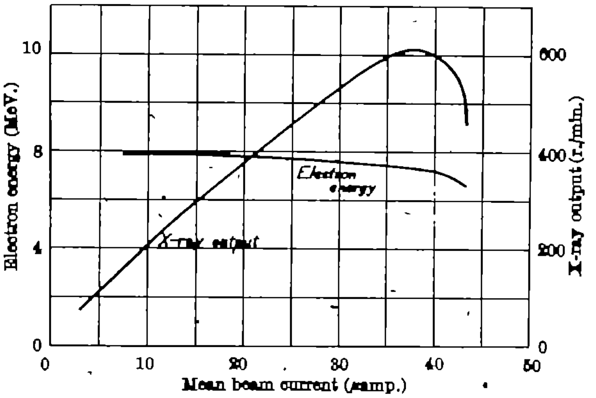

Fig. 2. Typical performance curves of linear accelerator at 500 pulses/sec. operation. Electron energy is that at the peak of the spectrum; X-ray output is measured without the clinical head

In the light of experience gained in this development, a 4-MeV. accelerator for clinical use has been designed, and several of these machines are at present being constructed. In this design the length of the corrugated guide is only 1 m., and the whole of the accelerator is mounted on a rotatable support. Considerable attention has been given to the simplification of the controls and of the facilities for the setting-up of the patient.

It is a pleasure to acknowledge the contributions of colleagues, and also the collaboration of the Atomic Energy Research Establishment and the Medical Research Council.

# HOMOLOGY OF THE LAYERS OF THE EPICUTICLE OF INSECTS

By Prof. R. DENNELL and Dr. S. R. A. MALEK
Department of Zoology, University of Manchester

THE insect epicuticle is known to be a complex structure, and the different views that have been put forward regarding its constitution have been difficult to reconcile. Wigglesworth has indicated the presence in *Rhodnius*[1], *Tenebrio*[2] and *Periplaneta*[3] of four epicuticular layers—the cuticulin, polyphenol, wax and cement layers. In contrast, Richards and Anderson had been able to demonstrate by different methods only two in *Periplaneta*[4], and later Dennell described a two-layered epicuticle in blowfly larvæ[5]. Neither of the two layers described by these authors appeared to have its obvious counterpart in the description given by Wigglesworth. Now, however, comparison is aided by more detailed information on the epicuticle of *Periplaneta* and of the larva of *Calliphora*.

The innermost layer of the epicuticle of *Periplaneta* is the chitin-free cuticulin layer readily recognizable by its mosaic appearance[3]. When fully hardened, it shows no affinity for stains, and takes up sudan black *B* only after treatment with 'Diaphanol'. It gives a strongly positive argentaffin reaction, and fuses into oily droplets on heating with chlorated nitric acid. On the other hand, the newly formed cuticulin layer stains red with Mallory's triple stain, and takes up sudan black without previous treatment due to the presence of lipoid now found to be of sterol type. The argentaffin reaction is positive but less intense than in the fully hardened cuticle. As Wigglesworth found in *Rhodnius*[6], hot concentrated solution of potassium hydroxide causes complete dissolution. The newly formed cuticulin layer therefore bears a striking resemblance to the inner layer of the epicuticle of blowfly larvæ. In *Sarcophaga* the 'inner epicuticle' or 'protein epicuticle' stains red with Mallory, dissolves in hot concentrated potassium hydroxide solution, and gives only a slight argentaffin reaction and sudan black staining[5]. In *Calliphora*, however, it is strongly argentaffin[5], and on re-examination has been found to contain a sterol. It seems, therefore, that the inner epicuticle must be regarded as homologous with the cuticulin layer of the cockroach, the differing properties that have been ascribed to this layer being due to the observation of differing degrees of impregnation of a basal protein matrix with steroid and further protein and their subsequent polymerization, and to tanning in the hard cuticle. A further indication of homology is that both the inner epicuticle of blowfly larvæ[7] and the cuticulin layer of the cockroach[9] contain a polyphenol oxidase at the time of hardening.

Overlying the inner epicuticle of blowfly larvæ is the very thin but resistant outer epicuticle or 'lipoid epicuticle'[5]. Its disruption into oily droplets on strong heating in chlorated nitric acid caused it to be wrongly regarded as cuticulin[10]. Like the inner epicuticle, it does not contain chitin. Isolated as already described[5], it has been further studied in *Calliphora*. It shows a strong X-ray diffraction pattern of paraffin-chain type and, in spite of the method of preparation, a weak diffuse protein pattern. The infra-red spectrum shows great C—H absorption with strong evidence of the presence of fatty acid esters. Micro-chemical analyses show that the nitrogen content amounts to only about 1 per cent. The outer epicuticle differs then from the cuticulin layer in containing not a steroid but a straight-chain paraffin.

Does such a thin layer of great stability occur also in hard cuticles? As is to be expected, it is found in puparia, and may be isolated by its persistence after treatment with 'Diaphanol' followed by hydrochloric acid. Richards and Anderson[4] found a resistant outer layer in the cockroach, and this observation has been amply confirmed in the present work. The soft cuticle of the newly moulted cockroach has been macerated and a very thin non-mosaic membrane lifted here and there from the underlying cuticulin layer. Where it remains in contact with the cuticulin layer, it is not histologically distinguishable, but a uniformly lifted cement layer is clearly seen. In the adult cuticle a thin stable membrane has been isolated by the treatments used for blowfly puparia. It is noteworthy that Wigglesworth[1] also has shown the presence in *Rhodnius*, before the secretion of the cement layer, of a superficial layer of greater resistance than the underlying cuticulin layer. Both cuticulin and the superficial layer, however, yielded oily droplets on dissolution in chlorated nitric acid, and Wigglesworth did not regard the two layers as chemically different. But the paraffin-containing outer epicuticle of *Calliphora* also yields oily droplets, and it is suggested here that the thin resistant layer of the cockroach cuticle is a paraffin-containing layer homologous with that of *Calliphora*. Unfortunately, sheets of this layer from the cockroach are not sufficiently robust to be examined by X-ray diffraction and infra-red absorption methods.

Turning now to the polyphenol layer of Wigglesworth's scheme, this is said to be formed as a discrete layer by the spreading and fusion of argentaffin droplets secreted at the tips of the pore canals[1,2]. But later the areas reducing ammoniacal silver nitrate are less prominent[3], and Wigglesworth's observations seem to permit the view that the argentaffin secretion may impregnate underlying layers in preparation for the hardening process. This is further suggested by the fact that these layers, when first laid down, do not give the argentaffin reaction[1,2], whereas at the time of moulting the test is positive before the general tanning of the cuticle begins. With regard to the nature of the argentaffin droplets it seems unlikely that a polyphenol is involved. The ferric chloride test is negative[9], and the argentaffin test is not specific for polyphenols. It has been shown in the cockroach cuticle[9] that, during preparation of the outer procuticle for tanning, a protein giving the argentaffin reaction is passed into a zone already occupied by a steroid, and it is suggested here that the 'polyphenol' secretion is a protein which similarly impregnates the sterol-containing cuticulin layer as a preliminary to the tanning process. Richards[8] admits the possibility that the polyphenol layer may be dispersed by, and modify, the underlying layers. In the view presented here, then, the polyphenol layer is not regarded as a constituent layer of the epicuticle.

To summarize, the insect epicuticle is regarded, in the light of our present knowledge, as basically comprising an innermost layer, the protein epicuticle, which during development of the cuticle is impregnated first by a steroid and then by an additional protein. It may then undergo quinone tanning to become the fully formed cuticulin layer described by Wigglesworth. The impregnating protein of the cuticulin layer may be secreted by the tips of the pore canals. Overlying the cuticulin layer is a very thin, chemically stable, paraffin-containing layer, the lipoid epicuticle. In some cuticles a cement layer may protect or be embedded in a wax or grease layer. In the accompanying table this view of the epicuticle is compared with that of Richards[8] and of Wigglesworth[1].

| Richards | Wigglesworth | Dennell and Malek |
|---|---|---|
| Tectocuticle | Cement layer | Cement layer |
| Lipoid epicuticle | Wax layer | Wax layer |
| Quertal | Polyphenol layer | Not recognized as a discrete layer |
| Lipoprotein layer | More resistant surface of cuticulin layer | Lipoid or paraffin epicuticle |
| Basal protein layer | Main mass of cuticulin layer | Protein epicuticle which may be impregnated with steroid and protein to form cuticulin layer |

We are indebted to Dr. K. M. Rudall for kindly making the X-ray diffraction and infra-red absorption observations for us. A more detailed account of the observations which form the basis of the views presented here will be given elsewhere.

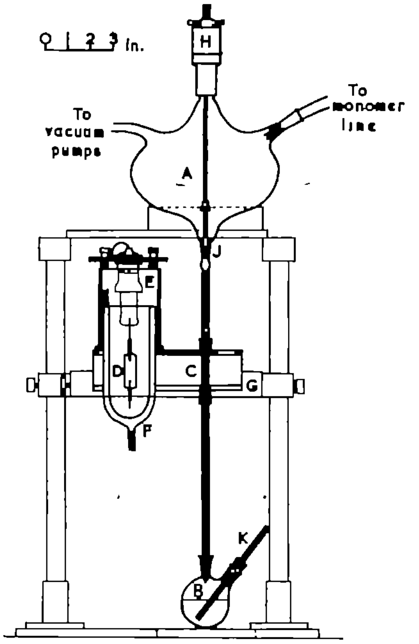
## A Flow Method for the Synthesis of 'Block' Copolymers

Two methods of synthesizing 'block' copolymers have been reported in a recent communication from these laboratories[1]. Whereas both these methods involve a static system, it has now proved possible to conduct a similar kind of synthesis using a flow technique. Polymer radicals derived from one monomer are introduced into a second monomer; their continued growth leads to the production of block polymer. The type of apparatus used for these experiments is shown in the diagram.



Monomer containing photo-sensitizer (1-azo-1-*bis*-*cyclo*hexanoic carbonitrile) flows down a vertical capillary (*C*) into a receiver (*B*). The rate of flow can be varied by means of a stainless steel valve (*J*) at the top of the capillary. Since oxygen is an inhibitor of vinyl-type polymerizations, all operations are carried out *in vacuo* and the valve is controlled externally from a vacuum-tight metal bellows attachment (*H*). Very high concentrations of free radicals (up to $10^{-4}$ mole/litre) are produced at any desired point inside the capillary by focusing into it a large proportion of the radiation from a 125-W. high-pressure mercury lamp (*D*). This is achieved by using an elliptical cylinder of stainless steel strip (*G*), highly polished on its interior surface to act as a reflector, the lamp being housed at one focus of the ellipse and the capillary at the other. The input rate, as determined by uranyl oxalate actinometry, is $2 \cdot 8 \times 10^{-7}$ Einsteins/sec. in the region of absorption by the sensitizer; the volume of liquid under illumination is only 0·03 ml.

In order to test the feasibility of introducing polymer radicals into the receiver, butyl acrylate was chosen as monomer since it has an unusually low rate coefficient for termination ($1 \cdot 8 \times 10^4$ litre mole$^{-1}$ sec.$^{-1}$ at 15° C.)[2]; at the rates of more than 100 per cent polymerization per hour inside the capillary, the life-time of the radicals is of the order of one second. The concentration of radicals attained inside the capillary depends on the length of the zone of illumination, the concentration of the sensitizer and the rate of flow of the monomer. It is essential in this method that the radicals emerging from the capillary should be dispersed immediately in the monomer contained in the receiver, thus increasing their life-time. Forced vibrations set up in a spring-steel strip (*K*) prove efficient for this purpose. Under these conditions the amount of polybutyl acrylate formed in the receiver is highly dependent on the number of radicals reaching it, namely, on the rate of flow and the distance of the mirror from the receiver. This may be seen from the accompanying table, in which $v$ is the velocity of the monomer, $P$ the concentration of polymer radicals at distance $d$ from the mirror, $F_1$, $F_2$ the calculated amounts of 'dead' polymer formed in the illumination zone and the capillary respectively, and $F$ the total amount of polymer formed.

| | | | | | |
|---|---|---|---|---|---|
| $v$ (cm./sec.) | 30 | 18·5 | 15·3 | 9·9 | 7·2 |
| $d$ (cm.) | 20 | 9 | 10 | 10 | 10 |
| $P \times 10^4$ (moles/lit.) | 0·42 | 1·0 | 1·4 | 2·2 | 2·5 |
| $F_1 + F_2$ (gm./lit.) | 0·04 | 0·07 | 0·15 | 0·48 | 0·83 |
| $F$ (calculated), gm./lit. | 0·75 | 1·29 | 1·91 | 2·45 | 3·25 |
| $F$ (obtained), gm./lit. | 0·9 | 1·12 | 1·95 | 2·5 | 3·4 |

The calculations are based on the theory of the non-stationary phase of chain reactions[3] and on general considerations of flow systems. It is possible to calculate $F_3$, the amount of polymer formed in the receiver; if a value of 40 sec. is assumed for the time required for polymerization in the system to cease, then the calculated values for $F$ are in agreement with those obtained from refractometric, measurements. The amounts of polymer formed in the system are given by:

$$F_1 = \frac{k_p}{k_t} . \ln \left( \cosh \frac{t_1}{\tau} \right), \quad F_2 = \frac{k_p}{k_t} . \ln \left(1 + k_t . P_M t_2\right)$$

$$\text{and } F_3 = k_p \int_0^{u} P . dt,$$

where $k_p$ and $k_t$ are the rate coefficients for propagation and termination, $t_1$ and $t_2$ are the times spent by the monomer in the zone of illumination and afterwards in the capillary, $\tau$ is the life-time of the radical in the stationary-state treatment, and $P_M$ is the maximum concentration of radicals attained in the system. The table also shows that $(F_1 + F_2)$ is much less than $F$, that is, most of the polymer radicals are terminated in the receiver and not inside the capillary. It should be possible to control the chain-lengths of the polymer radicals before they react with the second monomer, and the only restriction on the preparation of 'tailored' block polymers from a variety of monomer pairs is that the radicals from one monomer must react with the second monomer.

So far, two types of block polymer have been synthesized by this method. After running polybutyl acrylate radicals into styrene monomer, the polymer was isolated under such conditions that further thermal copolymerization was negligible. These runs were carried out at high rates of flow, so that the amounts of pure polybutyl acrylate formed and the percentage of this polymer in the block polymer were small. Ultra-violet analysis indicates a polystyrene content of approximately 72 per cent by weight.

The second type was made by running polyacrylonitrile radicals into styrene monomer, analysis indicating 76 per cent polystyrene in the product. It was soluble in chloroform only with difficulty. None of the turbidity usually associated with the heterogeneous polymerization of acrylonitrile was observed in the capillary. Since it has been demonstrated in a blank experiment that the polymer formed cannot be due to sensitizer radicals reaching the styrene, it appears that the initial stages of acrylonitrile polymerization may be homogeneous.

## Effects of Alkyl Groups in Nucleophilic Substitution

This communication refers mainly to the polar effects of alkyl groups in $S_N2$ reactions, in structural circumstances in which steric factors are absent. Rate comparisons showing the effects of methyl and *tert.*-butyl substituents are summarized in the accompanying table. Reactions (1) to (7) and (9) are of the type

where $Cab—X$ is, for example, $CH_2$—hal., $CH_2—\overset{+}{N}$, CO—OEt, or CO—hal., and $:Y = \bar{I}$, $\bar{O}H$ or $\bar{O}R$ (the dots represent electrons). Reactions (1)–(6) are of the second order, being of the first order with respect to each of the reactants specified. In the solvolytic process (7), the reagent (ethanol) is in large excess and the reaction is of the first order. It is probable, however, that this change is also substantially bimolecular[1]. Reaction (9) is a first-order replacement at a saturated carbon atom under conditions especially conducive to a unimolecular mechanism[2]. It was included in order to obtain a comparison of the effects relating to the two main substitution mechanisms, $S_N2$ and $S_N1$. Reaction (8) is a second-order nucleophilic replacement; but it should be noted that, in contrast to the other changes, it occurs at an aromatic carbon atom.

The polar requirements of the unimolecular mechanism (reaction 9) are clear. The rate-determining process consists of the separation of the expelled group with the electrons of the $C—X$ bond, and it should be facilitated unconditionally by electron release to the reaction centre. Consistently, it is observed that the *p*-alkyl substituents in reaction (9) give rise to a large increase of rate. The results show that *p*-Me has a greater capacity for electron-release than *p*-Bu$^t$, and they thus confirm a previous demonstration of C—H hyperconjugation influences in suitably situated alkyl groups[3].

In the bimolecular mechanism, the polar requirements are not so clear-cut. In this single-stage process, bond formation occurs simultaneously with bond fission; and, while bond fission should, as before, be facilitated by electron-releasing alkyl groups, the approach of the nucleophilic reagent, which is necessary for bond formation, should be hindered by these substituents. The net result is a difference effect; and, while it is not possible in general terms to make a simple prediction of its direction, the magnitude of the effect of a given substituent in $S_N2$ reactions may be expected to be smaller than the corresponding influence in $S_N1$ replacements. In reactions (1)–(4), alkyl groups increase the rate of substitution; but in examples (5)–(8) these substituents decrease the rate. In all cases, the observed effects are considerably smaller than the corresponding influences in unimolecular substitution (reaction 9). In the first set of bimolecular processes, bond-fission requirements are dominant, and the facilitating electron-release effects from the methyl substituents are greater than those from the *tert.*-butyl groups. In the second set, bond-forming requirements are dominant and the (now inhibiting) electron-releasing power of Me is again greater than that of *t*-Bu. The rate sequence *p*-H > *p*-Bu$^t$ > *p*-Me has also been observed for the reaction of 2-nitrobromobenzenes with pyridine, and confirmatory results have been obtained for reaction (6)[4].

The results, as a whole, show that C—H hyperconjugation effects, which are available in the *p*-methyl derivatives but not in the *p*-Bu$^t$-compounds, are of importance in bimolecular nucleophilic substitution under the conditions used. It should be emphasized that, because of the marginal requirements of $S_N2$ reactions, coupled with the dual

Reaction Rates showing Polar Effects of Alkyl Groups

behaviour of alkyl substituents, changes in experimental conditions (for example, temperature, solvent) may produce different rate sequences. Our extensions of these investigations will include a study of the Arrhenius parameters of the reactions under various experimental conditions, and we postpone further discussion of the effects until additional observations are available.

*Note added in proof* (*cf. ref.* 4). See *J. Amer. Chem. Soc.*, 74, 4940 (1952); because of differences in experimental conditions the absolute rate coefficients, for identical esters in the parallel investigations, are appreciably different, but the rate ratios, $p$-$R$/$p$-H, are in closer agreement.

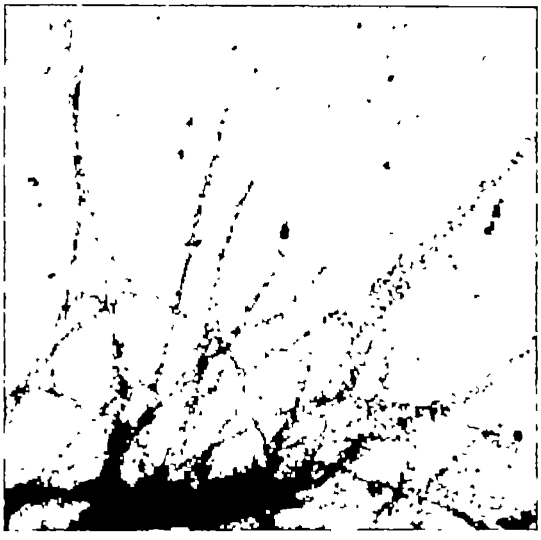
## Reticulin and Collagen

A RECENT letter by Little and Kramer[1] reporting some studies on reticulin prompts the submission of a preliminary account of some similar investigations now in progress. Attempts to determine the relation between collagen and reticular fibres using the electron microscope to examine teased-out or otherwise broken-down tissues are open to the criticism that the fibres observed are not histologically identifiable. Kramer and Little appear to have overcome this objection and to have reached the conclusion that the fibrils of reticulin have the same structure as collagen fibrils—a conclusion which the following experiments confirm.

The reticulin of adult rat and human spleens has been investigated using two different procedures. In the case of rat spleen, the method was to cut 10-μ frozen sections which were mounted on collodion films on fine stainless steel mesh, and then to digest these sections with pancreatin until only the fibrous elements of the connective tissue remained. After thoroughly washing and drying, suitable pieces of mesh were cut out, the specimens shadowed with palladium and examined in the electron microscope. Apart from the collapse of the material on to the film on drying, the fibrous network is very little disturbed, and reticulin could be identified as branching and anastomosing networks of fine fibres, quite distinct from the relatively massive bundles of collagen. In all cases the reticular fibres showed the same characteristic cross-banding as is shown, for example, by rat tail tendon, a true collagen.



Collagen fibres from human spleen capsule after silver impregnation. × 20,000

The human spleen material was treated differently. A fresh spleen was cut into slices of about 5 mm. thickness, well washed and then digested in pancreatin until only a fibrous network remained. A well-washed slice of this material was fixed in formalin, washed, dehydrated and finally embedded in a camphor-naphthalene medium. This was sectioned at 10 μ, the sections being mounted on collodion films on glass. The embedding material was removed by sublimation *in vacuo*—a process which minimizes disturbance of the fibres. Optical micrographs of these preparations were compared with those of ordinary histological preparations of spleen, silver-impregnated and stained with Van Gieson's fluid. From this comparison the reticular fibres in the collodion-mounted specimens were clearly identified, and these fields were examined in the electron microscope after palladium shadowing. Again the reticular fibres show precisely the same banded structure as does true collagen obtained by teasing the splenic capsule.

It seems, therefore, beyond doubt that the fibres of reticulin are morphologically identical with those of collagen. This does not necessarily imply that the two kinds of fibre are identical in all respects. Indeed, their responses to the Bielchowsky–Foot silver impregnation technique are markedly different and remain to be explained. This phenomenon of argyrophilia is at present under investigation. The accompanying photograph is of human spleen capsule fibres teased out after Foot silver impregnation, and shows that the metal is deposited as particles of colloidal dimensions on the fibres, and is not a chemical combination with them. It would appear that silver staining is an interface phenomenon occurring at the fibre – ground substance boundary, and may depend more upon variations of the latter than on differences in the fibres.

These studies are continuing and will be published fully elsewhere.

## Photo-Insolubilization of Dextran

THE insolubilization of many dichromate-sensitized protein dispersions, notably albumins, gelatins, etc. after exposure to light, is well known and is the basis of most photo-engraving procedures[1]. Polysaccharides, such as starch and gum acacia, and polysaccharide derivatives such as methyl cellulose and, more recently, surface-hydrolysed cellulose esters[2], similarly become insoluble when exposed to light in the form of thin, dry films.

It has been shown recently in these laboratories that dextran, a poly-glucose obtained by the fermentation of sucrose by a number of organisms, more particularly *Leuconostoc* species, also exhibits photo-insolubilization, a property which is very clearly demonstrable with the water-soluble dextran produced by the *L. mesenteroides* organism described by Stacey and Swift in 1948[3]. Degradation of the macromolecule[4] produces nitrogen-free fragments which can be separated into homologous polysaccharide fractions of differing molecular sizes. It has been shown that these degraded polysaccharides are also capable of being photo-insolubilized, and the interesting discovery has been made that there appears to be a relationship between molecular size (expressed in terms of viscosity) and light sensitivity.

In general, preparations with molecular weights in excess of one million show a greater speed of insolubilization as compared with preparations having molecular weights of less than 500,000. Preparations with mean molecular weights in the region of 300,000 show rates of insolubilization comparable with the proteins conventionally used in photo-mechanical processes. Variation of dichromate concentration does not appear to affect the rate of insolubilization, that is, the general sensitivity of these dextrans, to any marked degree.

After heating for two minutes at an optimum temperature of 250° C., the insoluble image has been found to be resistant to etching acids.

A more detailed account of this development will be published elsewhere.

## Effects of some Chelate Compounds upon the Formation *In vitro* of Melanin

It is said that cupric ions accelerate the autoxidation of 3,4-dihydroxyphenylalanine (dopa)[1] and, on the other hand, that they combine with pterins, riboflavin, amino-acids and other organic substances to form chelate complexes[2]. We have therefore carried out some experiments to investigate the behaviour of metal-bound pterins and riboflavin in relation to the rate of oxidation of dihydroxyphenylalanine.

Fig. 1 gives the results of manometric measurements indicating that the oxidation of dihydroxyphenylalanine is much more highly accelerated by the presence of both folic acid and cupric sulphate than by the presence of the latter alone, while folic acid itself appears to have no effect. The rate of blackening of the solution appears to be higher than that due to oxygen uptake, in the presence of both substances. Xanthopterin behaves similarly, and is more active than folic acid in the presence of cupric ions, whereas leucopterin does not accelerate the oxidation even if accompanied by cupric ions.

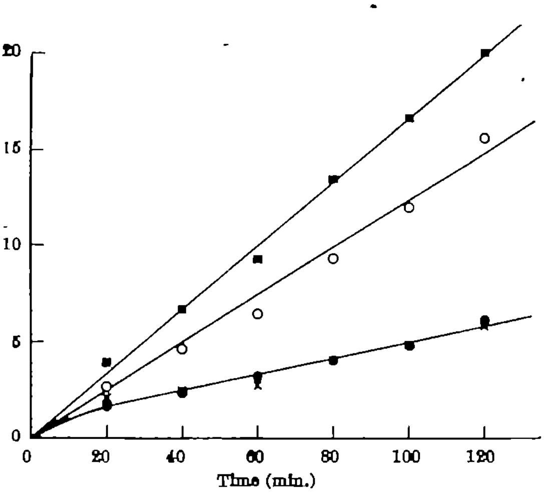

Fig. 1. Acceleration of oxygen uptake by dihydroxyphenylalanine due to the chelate compound of folic acid and cupric ions (pH 7·8, 37·5° C.).
—●—, 0·5 c.c. of $M/15$ phosphate buffer solution and 1·8 c.c. of distilled water in the main chamber.
—×—, 1 c.c. of distilled water in the first preparation replaced by 1 c.c. of 80 mgm. per cent folic acid suspension.
—○—, 0·5 c.c. of distilled water in the first preparation replaced by 0·5 c.c. of $10^{-3}$ $M$ cupric sulphate solution.
—■—, 1·5 c.c. of distilled water in the first preparation replaced by 0·5 c.c. of $10^{-3}$ $M$ cupric sulphate solution and 1 c.c. of 80 mgm. per cent folic acid suspension.
Each of the side arms of the manometric flasks contained 0·5 c.c. of 60 mgm. per cent solution of dihydroxyphenylalanine, which was transferred into the main chamber at 0 hr. Each of the wells contained 0·3 c.c. of 10 per cent solution of potassium hydroxide

These results suggest that pterins, when they form chelate compounds with certain metals, behave like enzymes in accelerating the autoxidation of dihydroxyphenylalanine, their activities being different according to structures of their rings. In this connexion, the investigations of E. L. Smith[3] were of much interest to us, for they interpret enzymic activities by rather simple principles which fundamentally are based upon the chelation of organic substances with metallic ions.

Riboflavin, the photodynamic accelerator of the autoxidation of dihydroxyphenylalanine[4], is also known to form larger complexes by capturing

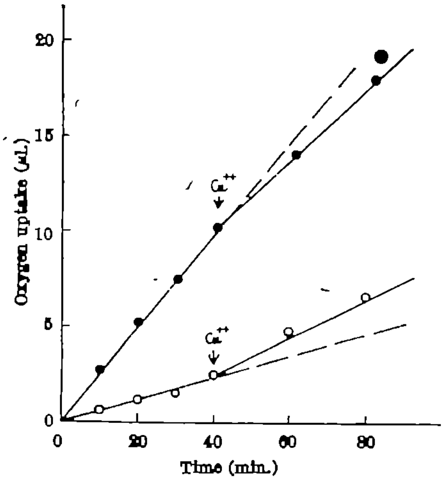

Fig. 2. Effect of riboflavin on oxygen uptake by dihydroxyphenylalanine, before and after the addition of cupric ions, under irradiation with a 200-W. tungsten lamp (pH 7·8, 37·5° C.).
—○—, 1 c.c. of 60 mgm. per cent solution of dihydroxyphenylalanine, 0·5 c.c. of $M/15$ phosphate buffer solution and 0·8 c.c. of distilled water in the main chamber.
—●—, 0·5 c.c. of distilled water in the first preparation replaced by 0·5 c.c. of $10^{-4}$ $M$ solution of riboflavin.
Each of the side arms of the manometric flasks contained 0·5 c.c. of $10^{-3}$ $M$ solution of cupric sulphate, which was transferred into the main chamber 40 min. after the beginning of measurement. Each of the wells contained 0·3 c.c. of 10 per cent potassium hydroxide

metallic ions[3]. We therefore examined this substance before and after it was mixed with cupric sulphate. Our results show a sharp contrast to those given by pterins. As Fig. 2 shows, the accelerating effect of riboflavin was much hindered by the addition of cupric ion which, if added independently, could accelerate the oxidation to a certain extent. A mixture of riboflavin and copper also showed less degree of acceleration than that of riboflavin alone. We believe that this may be due to the decrease of photodynamic activity of riboflavin, which was found previously to be proportional to the intensity of fluorescence[4], for we found that contact with the metal resulted in a considerable weakening of the fluorescence from riboflavin.

Another example of the effect of chelation may be mentioned. Zinc ion is the only metallic ion reported to accelerate the conversion of dopa-chrome (red substance) to leuco-substance—the second step in the formation of melanin[5]. This can be confirmed in Thunberg tubes. We prepared dopa-chrome by adding sodium hydroxide to dihydroxyphenylalanine. After neutralizing with hydrochloric acid, we put it into a Thunberg tube, de-aerated and mixed it with zinc sulphate at $p$H 6·8. The red colour disappeared gradually. Now, if xanthopterin was added to this system, the time of decolorization was prolonged somewhat. This again may be attributed to the capture of the metallic ion by xanthopterin, for the latter alone could have little effect upon this step.

Further details of our investigations will be published elsewhere.

## Stepwise Degradation of Polypeptides from the Carboxyl End

Many methods have already been described for the selective degradation of peptides from the carboxyl end[1]. However, the several chemical steps involved in those procedures do not allow their utilization on a micro-scale. Linstead, Shephard and Weedon[2] have recently published a study on the decarboxylation of α-N-acylamino-acids in alcoholic media by anodic oxidation into alkoxyalkylamides (acylaminoethers), with a 74–91 per cent yield.

We applied the same anodic oxidation on a micro-scale to N-acyl derivatives of polypeptides (1 cm.$^3$ of 0·1 per cent solution in methanol; platinum electrodes of 1 cm.$^2$ total surface area, 3 mm. apart; 200–250 volts, D.C.; 50–150 m.amp.; 10–30 min.; 0° C.). The initial amino-acid of the acylated peptide (I) is decarboxylated into (II):

$$\begin{tikzcd} \underset{\text{(I)}}{X\text{—NH.CH}R'\text{.CO—NH.CH}R\text{.CO}_2\text{H}} \arrow[r] & \underset{\text{(II)}}{X\text{—NH.CH}R'\text{.CO—NH.CH}R\text{.OCH}_3} + \text{CO}_2 \arrow[d, "\text{HCl}"] \\ \underset{\text{(IV)}}{X\text{—NH.CH}R'\text{.OCH}_3} + \text{CO}_2 & \underset{\text{(III)}}{X\text{—NH.CH}R'\text{.CO}_2\text{H}} + \text{NH}_3 + R\text{.CHO} + \text{CH}_3\text{OH} \arrow[l] \end{tikzcd}$$

The initial amino-acid no longer appears on a paper chromatogram of the hydrolysis products of (II). If (II) is heated for a short time with dilute aqueous hydrochloric acid, the methoxyalkylamide is hydrolysed into (III). After evaporation to dryness *in vacuo* and re-dissolution in dry methanol, (III) is decarboxylated by a new anodic oxidation into (IV). The spot of the second amino-acid is no longer detectable on a chromatogram of the hydrolysis products of (IV).

By this simple method, which involves only manipulations easily carried out on a micro-scale, polypeptides were degraded stepwise from the carboxyl end, and the sequence of amino-acids was determined by their successive disappearance on chromatograms after hydrolysis.

We found that Sanger's dinitrophenyl derivatives of peptides may also be submitted to carboxyl anodic oxidation. Thus, time and material are saved by combining Sanger's method for the determination of the amino terminal amino-acid with our new method for the determination of the carboxyl terminal amino-acid.

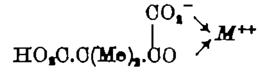
## Metal Ion Catalysis of the Decarboxylation of Oxalo-Acetic Acid

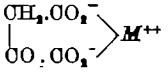
In order to explain the catalysis of oxalo-acetic acid decarboxylation by metal ions, intermediate complex formation between the metal ion and the acid anion has been postulated. In an attempt to determine the nature of this complex, Steinberger and Westheimer[1] studied the kinetics of the decarboxylation of the dimethyl substituted acid. In this way they showed that the catalysis did not proceed through an enolic form of the acid. From a further consideration of the general characteristics of decarboxylation reactions, they suggested that the metal complex involved in the catalysis had the formula, $MA$, which was formed from $MHA^+$, by the loss of a proton.

$MHA^+$



$$\text{HO}_2\text{C.C(Me)}_2\text{.CO—CO}_2^- \rightarrow M^{++}$$

$MB$



$$\text{CH}_2\text{.CO}_2^- \text{—CO.CO}_2^- > M^{++}$$

Pedersen[2] examined the catalytic decarboxylation of the parent acid in greater detail. He obtained, from kinetic data, a stability constant of $10^4$ for the formation of a cupric complex of the acid, and suggested that this complex was of the same kind as

*MA*. Now *MA* is a complex of an α-keto acid, and another complex, *MB*, could also have been formed. The latter is a complex of a dicarboxylic acid. The measurement of the stability constants for the formation of both types of complex together with the observation of Pedersen might then be used for describing in more detail the suggested mechanism of the catalysis. The data for the dicarboxylato-complexes are available from the literature, and we have measured the stability of the complexes of pyruvic acid in order to make this comparison (see table).

LOGARITHM OF THE STABILITY CONSTANTS OF CERTAIN METAL COMPLEXES

| Ligand | $pk_1$ | $pk_2$ | log $K_{Cu}$ | log $K_{Zn}$ | Ref. |
|---|---|---|---|---|---|
| Malonic acid | 2·86 | 5·70 | 4 80 | 3·68 | 7 |
| Succinic acid | 4·19 | 5·48 | 3·33 | 2·70 | 7 |
| Oxalo-acetic acid | 2·30 | 3·88 | 4·00 | — | 2 |
| Tartaric acid | 2·88 | 3 94 | — | 2·68 | 8* |
| Acetic acid | 4·75 | — | | 1·57 | 7 |
| Glycollic acid | 3·71 | — | — | 1·92 | 8* |
| Pyruvic acid | 2·35 | — | 2·50 | 2·10 | |

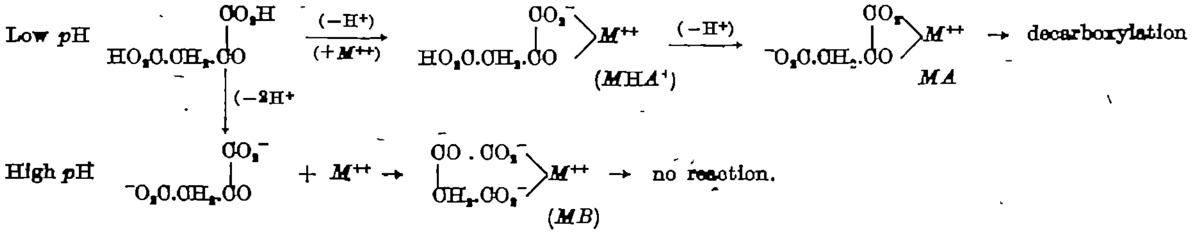
* Measured at ionic strength 0·2.

The data show that the stability constants of both the zinc and the cupric complexes of dicarboxylate anions have considerably larger values than those of the pyruvates. The value Pedersen[2] obtained is much nearer the former, and this might suggest that his complex constant referred to the formation of a complex of formula *MB*. However, the formation of the two complexes $MHA^+$ and *MB* is controlled by the *p*H such that the relative amounts of each are given by :

$$\frac{[MHA]}{[MB]} = \frac{K_1.[H]}{K_2.k_2}, \qquad (1)$$

where $K_1$ and $K_2$ are the stability constants for the formation of the complexes $MHA^+$ and *MB* respectively, and $k_2$ is the second acid dissociation constant of oxalo-acetic acid. From the data in the table and equation (1), the two different complexes might be expected in equal amounts at about *p*H 2·0–3·0. Below this *p*H the complex $MHA^+$ would predominate. It is to be expected that *MA* will only form in the *p*H range in which *MHA* is formed rather than *MB*. Now *MA* will have a different stability constant, $K_3$, from $MHA^+$ or *MB*, such that $K_3 = \frac{K_1.k_3}{k_2}$, where $k_3$ is the acid dissociation constant of $MHA^+$. As $k_3 < k_2$, Pedersen's constant, $K_3$, would be expected to be greater than $K_1$—as is found—and the determination of stability constants does not discriminate between *MA* and *MB*.

At higher *p*H values the formation of *MA* or *MB* need not proceed through $MHA^+$, and either one of the two complexes will be formed, depending only upon their relative stability. It is to be anticipated that *MB* will be the more stable, and the formation of this complex would account for the absence of catalysis at higher *p*H values[5]. The complete reaction scheme would then be :



The rate of some other catalysed hydrolyses have somewhat similar features to the above decarboxylation[4]; but it is of particular interest that the catalysis of many enzymatic reactions is similar to that described[5], and in particular that this catalysis also goes through a maximum with *p*H. The recent work of Albert[6] has illustrated further the importance of the formation of two different complexes from the same ligand and metal ion.

## Newton's Work on Geometrical Optical Aberrations

IN Newton's "Opticks" (editions of 1704, 1717 and 1721 and the subsequent editions and translations, so far as we have been able to ascertain) an erroneous condition is given for the proportion α of the radii of a symmetrical thin triplet (the inner lens being of water) in order to correct the system for spherical aberration for distant objects. Calling the curvature of the first and second surface $R_1$ and $R_2$ respectively, the formula gives $\alpha^3 = (R_1/R_2)^3 = (KK-KI)/(RK-RI)$, where $R/I = n_g$, the refractive index of the two outer (glass) lenses, and $R/K = n_w$, the refractive index of the inner (water) lens. The fraction can be simplified to $K/R$, and gives a large amount of under-correction.

No indication is left of the deduction of the condition. The correct and complete form is : $a\alpha^3 + b\alpha^2 + c\alpha + d = 0$, where $a$, $b$, $c$ and $d$ are functions of a high degree in $n_g$ and $n_w$. This form cannot by any reasoning be simplified to a cube root condition for α.

By means, however, of an unwarranted application of the formula for the spherical aberration of a single spherical surface for a parallel incident pencil, as given by Newton in "Lectiones Opticæ", I, Prop. 31, a curious result is obtained. When we transfer the angular aberration of the first surface to the image space by multiplication by $(n_g/n_w) . (n_w/n_g) . (n_g/1)$, doing the same for the aberration of the second surface with the factor $(n_w/n_g) . (n_g/1)$, for the third surface with the factor $n_g/1$, and adding the contributions of the four surfaces, we get the condition for the correction of spherical aberration :

$$\alpha^3 = (n_g - n_w)\,(n_g^4 + n_w^4)/(n_g - 1)\,(n_g^4 + 1)n_w^2.$$

Within the range of refractive indices for glass in Newton's time, it appears that the factor $(n_v^4 + n_w^4)/(n_v^4 + 1)n_w^2$ is practically constant and equal to $1/n_w$. Thus the condition for $\alpha$ can be written: $\alpha^2 = (n_v - n_w)/n_w(n_v - 1) = (\underline{KK} - \underline{KI})/(RK - KI)$. With the value of $\alpha$ following from it, the spherical aberration, indeed, is considerably reduced—to about 0·6 that of a single lens of best form (to reduce spherical aberration).

If this, indeed, was originally meant by Newton, only one letter in the formula had been erroneously printed; that the error is present in each edition can be explained by the fact that Newton had no interest in this condition on account of the chromatic aberration, which, according to him, was always present and larger, and which led him to the construction of a reflecting telescope.

Each of the letters of the original formula has been changed into one of the other possible letters; but the change as given above is the only one which leads to a better correction.

It was further ascertained that the correction outside of the axis for distant objects by means of a symmetrical thin ('cemented') triplet is always much worse than for a single lens of approximately convex-plane form, at least unless enormous amounts of spherical aberration are being introduced. This means that the Scholium to Prop. 98 of the first book of the "Principia" is either incorrect or refers to a non-symmetrical triplet.

It would be worth while, we think, to look into what is left of Newton's papers and letters to see if there is any indication that he had worked in this direction.

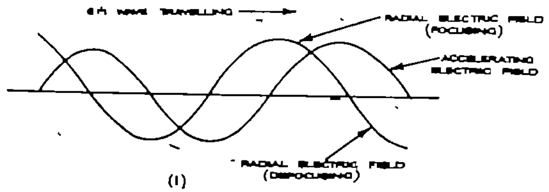
## A Heavy-Particle Accelerator

A method of overcoming the defocusing effect of the electromagnetic wave in the Walkinshaw heavy-particle accelerator[1] has been suggested by Chick and Petrie[2]; an alternative solution to the problem is here proposed.

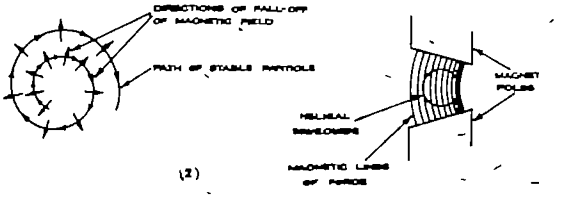
If the stable position for the particle bunch on the travelling wave could be made to lag in phase from the normal position by an angle between 90° and 180°, it would then be in a region of focusing instead of defocusing radial forces[3,4] (Fig. 1). For stability in this region, however, it is necessary that a particle which loses energy shall gain in phase on the electromagnetic wave, and vice versa. It is suggested that this can be achieved by introducing a constant magnetic field gradient across the helical guide, the axis of which should then be made to take the form of a spiral in the plane perpendicular to the magnetic field, the dimensions depending upon the magnetic field-strength and the rate of acceleration (Fig. 2).

A particle with an excess or deficit of energy will then leave the equilibrium orbit and pass into a region of lesser or greater magnetic field-strength. In the non-relativistic region, therefore, the angular velocity of a particle with an excess of energy can be made less than that corresponding to the stable orbit and vice versa (Fig. 3).



Wave travelling
Radial electric field (focusing)
Accelerating electric field
Radial electric field (defocusing)

(1)



(2)

The above mechanism will be modified by the presence of the radial electric focusing forces, which are the differential of the accelerating field. Phase stability will therefore be dependent upon both the magnetic field and the accelerating field.

It may be shown that phase stability exists if:

$$n > \frac{\pi r_s^2}{2\lambda_g E} F_s \cos\theta_1,$$

where $n = \frac{r_s}{H_s}\frac{dH}{dr}$; $r_s$ is radius of stable orbit; $\lambda_g$ is wave-length of accelerating field in the guide $\left(= \frac{v}{c}\lambda_a\right)$; $\lambda_a$ is wave-length of accelerating field in air; $v$ is velocity of particle; $c$ is velocity of light; $E$ is kinetic energy of the particle; $F_s$ is maximum value of electric accelerating field multiplied by charge on the particle; $\theta$ is phase angle defined as $\theta = 0$ for zero accelerating field. It may also be shown that radial-focusing exists if:

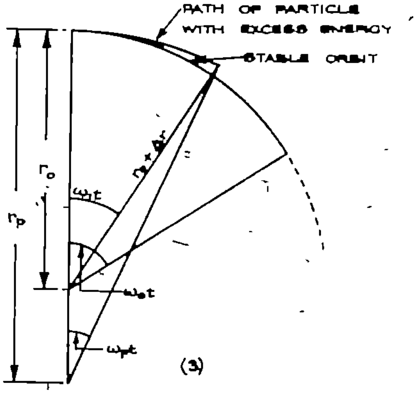
$$n - 1 < \frac{\pi r_s^2}{2\lambda_g E} F_s \cos\theta_2.$$

The phase angle over which particles will be captured will be $\theta_{1\max} - \theta_{1\min}$, where

$$\theta_{1\max} < \cos^{-1}\frac{2\lambda_g E}{\pi r_0^2 F_0}(n - 1);$$

$$\theta_{1\min} > \cos^{-1}\frac{2\lambda_g E}{\pi r_0^2 F_0}\, n.$$

From this it can be seen that $n$ may be made greater than 1 by reducing $\theta_{1\max}$.



(3)

$r_p\omega_p$ = velocity of particle.

Phase stability if, for $v_p/v_s > 1$, $d\omega_1/dt$ is negative, and $v_p/v_s < 1$, $d\omega_1/dt$ is positive

Since $\frac{\lambda_0 E}{r_0^2} \propto H_0^2$, we have $H_0^2 \propto \frac{1}{n-1}$,

and $H_0$ will therefore be smaller for larger values of $n$; from which it follows that the separation between successive revolutions will be greater for larger $n$. Advantage might have to be taken of this in a practical design to avoid the injector on the second revolution.

Using available figures[1,2] as typical operating conditions, we find for protons: injection energy, 2 MeV.; radio-frequency, 300 Mc./s.; $F_0$, 25 keV./cm.; $n$, 1; $r_0$, 20 cm.; $H_0$, 10 k.gauss; $\theta_{\text{max.}} - \theta_{1\text{min.}}$, 90°; energy gain in first revolution, 3 MeV. approximately; distance between first and second orbits, 12 cm. approximately. For $n = 1$, $\theta_{\text{max.}} = \pi/2$, so that the phase stability condition becomes dominant. Hence, for a constant value of $\theta_{1\text{min.}}$ and $n = 1$, $H_0$ will vary along the stable orbit as $E^{-1/4}$. Thus orbit separation may be increased as acceleration proceeds. Following the reasoning adopted by Thomas[5], the focusing and defocusing effects of so reducing the magnetic field along the stable orbit should cancel.

I wish to acknowledge the help I have received from discussions with members of the Radiotherapeutic Research Unit, in particular P. H. Flanders, during the preparation of this communication.

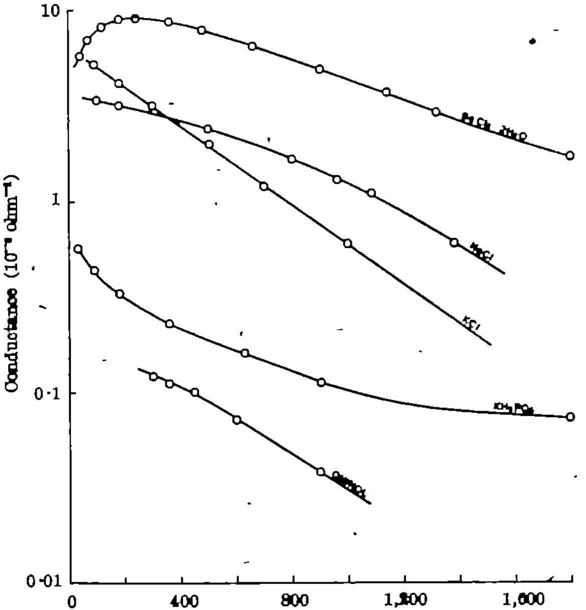
## Electrical Conductivity of Certain Crystalline Materials after Grinding

IT was recently reported[1] that quinol shows a large increase in low-frequency dielectric loss on grinding. The effect is temporary and decreases with time. It has now been found that this phenomenon is more general and occurs with many inorganic salts and some crystalline organic compounds.

In these materials the dielectric properties of the lightly pressed crystals before grinding are such that the loss factor increases with decreasing frequency and ultimately rises in proportion to $1/f$ (where $f$ is frequency); it is assumed that the loss factor in the latter region is entirely due to D.C. conduction. On grinding, the magnitude of the low-frequency dielectric loss factor increases at all frequencies, often by as much as a factor of 1,000.

The experiments were performed with electrodes in the form of bevelled brass pistons surrounded by a polystyrene cylinder, which enabled the grinding and measurement to be carried out in rapid sequence in a controlled atmosphere. The A.C. conductance at a particular frequency was measured as a function of time.

The results for four inorganic salts and for quinol, dried for several weeks over calcium chloride and then ground in air over calcium chloride, are given in the accompanying graph. Smaller effects were observed with urea, copper sulphate and resorcinol; and other compounds, such as sugar, paraffin wax and 4:4′-dihydroxy-diphenyl, gave no measurable effect.



Effect of grinding on the conductance of various crystalline materials at 16 kc./s.

Values of conductance before grinding ($10^{-8}$ ohm$^{-1}$): $BaCl_2.2H_2O$, 0·16; $KH_2PO_4$, 0·023; NaCl, 0·017; KCl, 0·005; quinol, 0·004

Several grinding experiments were performed with these electrodes in a vessel which could be evacuated or filled with any desired atmosphere. It was observed that the rate at which the A.C. conductance decreased, following the initial increase on grinding, was more rapid the lower the relative humidity of the surrounding atmosphere. Also, the equilibrium value of the A.C. conductance was less the lower the relative humidity. At pressures below about 5 mm. of mercury, no increase in A.C. conductance was observed on grinding. Moreover, if the increase had already been produced by grinding in a normal atmosphere, it was eliminated by evacuation.

The effect was not present in sodium or potassium chloride, or in quinol which had been thoroughly dried by heating and then ground in an atmosphere over phosphorus pentoxide. Even when such thoroughly dried materials were ground in the laboratory atmosphere, the increases in conductivity were small. On prolonged exposure to the laboratory atmosphere, the return to the state giving a large grinding effect was comparatively slow, particularly with sodium chloride.

The results of this work suggest that the low-frequency dielectric properties of these materials before grinding arise from the presence of highly conducting regions at the crystal surfaces due to adsorbed layers of water. Also, there is some water (or solution) held in the crystals, possibly in small cracks, which, on being released by grinding, distributes itself over the freshly created surfaces. The water present on these surfaces in excess of that in equilibrium with the surrounding atmosphere then evaporates, resulting in a decrease in the D.C. and A.C. conductances.

In connexion with these results, extensive experiments on the adsorption of gases on sodium chloride have been carried out by Durau[2], who found that prolonged heating was necessary to remove the last traces of water.

## Infra-Red Spectra of Coals and Coal Products

I WAS interested to read the comments of Gordon and his collaborators on the infra-red spectra of coal[1]. The spectral range of our earlier work[2] was limited to 1,000–10,000 cm.$^{-1}$, because our first thin sections were mounted on fluorite plates with a transmission limit of 1,000 cm.$^{-1}$. Later work, as yet unpublished[3], using the 'Nujol' dispersion technique[4], extended the spectra of coals to 650 cm.$^{-1}$, the limit of the rock-salt prism spectrometers used.

Spectra of eighteen samples of bright coals (that is, mainly vitrain) of varying rank from Warwickshire, Northumberland, Yorkshire and South Wales were recorded. Humic acids, and pyridine and aniline extracts from several of the coals, were also examined. Most of the strong absorption bands were assigned to specific chemical groups present in the coal structure. The results and major conclusions are briefly summarized here.

The general level of absorption intensity was constant for the lower-rank coals. The general absorption intensity was higher for a coking coal and very much higher for a low-volatile steam coal. Gordon's spectrum of an anthracite[1] is almost devoid of structure except at the low-frequency end. Graphite examined in 'Nujol' at the same path-length as used for the coals was completely opaque from 5,000 cm.$^{-1}$ to 650 cm.$^{-1}$. A 'Nujol' dispersion c. 2 μ thick showed a continuous structureless absorption of 70–80 per cent over this spectral range. This marked increase in general absorption for the high-rank coals can be correlated with the development of optical anisotropy[5], and with orientation and growth of crystalline regions found in X-ray diffraction studies[6]. It seems to mark the beginning of a transition from an aromatic structure (see below) towards a graphite-type structure.

The general similarity in the spectra of coals of all ranks examined (except anthracite[1]) suggests that the molecular skeleton remains practically unchanged. As one might expect from the decrease in oxygen content with increase in rank, bands which can be assigned to oxygen-containing groups (OH, C=O, C—O—, etc.) decrease in intensity with increase of rank. The main absorption assigned to the C—O— stretching-frequency occurs in the region of 1,250 cm.$^{-1}$, suggesting that the OH groups are mainly phenolic rather than aliphatic hydroxyl.

The molecular structure seems very complex, but the C—H and —C=C— stretching frequencies, and the CH out-of-plane deformation frequencies near 880, 820 and 750 cm.$^{-1}$, when correlated with the spectra of a large variety of aromatic compounds[7], indicate the presence of both single ring and condensed aromatic structures. Aliphatic CH$_2$- and CH$_3$-groups can be detected. Two carbonyl frequencies have been found; the stronger, near 1,690 cm.$^{-1}$, probably arises from aldehyde or keto-groups, while the second, near 1,730 cm.$^{-1}$, suggests the presence of a smaller proportion of ester groups.

For a low-rank coal, the spectrum of the material extracted by pyridine was practically identical with that of the parent coal.

A study of the hydroxyl frequencies in the spectra recorded suggests that hydrogen bonding between hydroxyl groups is one of the factors determining the physical structure of coals. Orchin and Storch[8] have postulated a hydrogen-bonded structure for coal, following their work on solvent extraction. Dryden[9] has briefly discussed the significance of the spectroscopic results and the part played by hydrogen bonding in the solvation of coals.

The humic acid spectra were clearly different from those of the parent coals, and had features in common with graphitic acid and mellitic acid (hexacarboxybenzene).

As Gordon *et al.* have noted[1], pitch extracts exhibit spectra bearing a remarkable resemblance to the coal spectra. Hadži[10] has studied the spectra of a variety of coal and tar extracts and has identified chemical groupings also found in the coal spectra.

The results summarized above, which were obtained several years ago, will be published in detail elsewhere.

I am indebted to Prof. G. B. B. M. Sutherland for his guidance during the course of this work, and to the late Dr. D. H. Bangham for his interest and encouragement. Thanks are also due to Prof. R. G. W. Norrish for facilities kindly provided in the Laboratory of Physical Chemistry, Cambridge. The research was sponsored by the British Coal Utilization Research Association and permission to publish this work is gratefully acknowledged.

## A Trigonometric Series used in Physical Problems

IN connexion with a boundary-value problem in room acoustics, we were led to consider the following trigonometric series. It has been noted further that certain other trigonometric series encountered by K. S. Krishnan[1,2] and L. S. Goddard[3] in different physical situations can be obtained as special cases of the above series.

The series concerned is:

$$\sum_{n=1}^{\infty} \frac{\sin(n+\theta)x}{n+\theta} \cdot \frac{\sin(n+\varphi)x}{n+\varphi} = A(\theta,\varphi;\ x), \text{ say,}$$

$$0 < x < \pi,$$

and $A(\theta,\varphi\,;\,x)$ can be expressed as

$$\frac{1}{2}\,\frac{\cos(\theta-\varphi)x}{\theta-\varphi}\,[\psi(1+\theta)-\psi(1+\varphi)]+$$
$$\frac{1}{2}\,\frac{\cos(\theta-\varphi)x}{\theta-\varphi}\,[c(\theta,2x)-c(\varphi,2x)]+$$
$$\frac{1}{2}\,\frac{\sin(\theta-\varphi)x}{\theta-\varphi}\,[s(\theta,2x)+s(\varphi,2x)],$$

where

$$\psi(x)=\frac{\Gamma'(x)}{\Gamma(x)},\quad c(\theta,x)=\sum_{n=1}^{\infty}\frac{\cos(n+\theta)x}{n+\theta},$$
$$s(\theta,x)=\sum_{n=1}^{\infty}\frac{\sin(n+\theta)x}{n+\theta}.$$

The transformations for $c(\theta,x)$ and $s(\theta,x)$ were obtained by G. H. Hardy[4].

Putting $\theta=\varphi$ and taking the sum of $A(\theta,\theta\,;\,x)$ and $A(-\theta,-\theta\,;\,x)$, one obtains the result (Krishnan, *loc. cit.*):

$$\sum_{n=-\infty}^{\infty}\frac{\sin^2(nx+\alpha)}{(nx+\alpha)^2}=\frac{\pi}{x}.$$

Putting $\theta=-\varphi=\alpha m$ ($\alpha>1$, $m=1,2,3\ldots$) and $x=\pi/\alpha$, one obtains (Goddard, *loc. cit.*):

$$\sum_{n=1}^{\infty}\frac{\sin^2(n\pi/\alpha)}{n^2-\alpha^2m^2}=0.$$

The corresponding series involving the cosines, namely,

$$\sum_{n=1}^{\infty}\frac{\cos(n+\theta)x}{n+\theta}\cdot\frac{\cos(n+\varphi)x}{n+\varphi}=B(\theta,\varphi\,;\,x),\text{ say,}$$

can also be treated in the same manner.

The last series can be used to obtain the result

$$\sum_{n=-\infty}^{\infty}\frac{\cos^2(nx+\alpha)}{(nx+\alpha)^2}=\left(\frac{\pi}{x}\right)^2\left[\operatorname{cosec}^2\left(\frac{\pi x}{\alpha}\right)-\frac{x}{\pi}\right].$$

The details of the calculations and certain other results will be published elsewhere.

## Multiple Meson Production

It has recently been reported by Daniel *et al.*[1] that in high-energy collisions between nucleons, besides π-mesons, some heavier mesons of about 1,300 $m_e$ mass are also created. The purpose of the present note is to estimate the theoretical probability of emission of a heavy meson in a collision process, using the statistical theory developed by Fermi[2]. The collision is studied in the centre-of-mass system of the particles and it is assumed that the total energy $W$ ($W$ is the energy in the centre-of-mass system) is suddenly released in a small volume,

$$\Omega=\frac{4\pi}{3}(\hbar/\mu c)^3\,2Mc^2/W,$$

surrounding the nucleons ($M$ = mass of the nucleon, $\mu$ = mass of π-meson). One then calculates statistically the probability that a certain number of mesons are created.

On a suitable modification of Fermi's results, we find that the probability, $P(s,n)$, of two nucleons, $s$ heavy mesons (of mass $K$) and $n$ π-mesons being present in the final state of collision, is given by:

$$P(s,n)=\frac{8\cdot5}{(2+s)^{s/2}}\,\frac{(29\cdot3/\omega)^{s/2}}{\{(6n+3s+1)/2\}!}\,.$$
$$\left\{\frac{6\cdot31}{\omega^{1/3}}\left(\omega-2-\frac{2}{3}s\right)\right\}^{3n+\frac{3}{2}s+\frac{1}{2}}\exp\left\{-\frac{6\cdot31}{\omega^{1/3}}(\omega-2)\right\}$$

where $\omega=W/Mc^2$ and we have taken $K/M=2/3$; $\mu/M=0\cdot15$. In deriving the above result the nucleons and the heavy mesons have been treated in the non-relativistic approximation, whereas π-mesons have been treated in the extreme-relativistic approximation. Further, the conservation of angular momentum has not been considered.

The table gives the results obtained from the above formula.

| $\omega$ | Energy of primary particle in laboratory system | Average number of π-mesons produced when no heavy meson is created | One heavy meson is created | | Ratio of the number of heavy mesons to π-mesons created in a collision |
|---|---|---|---|---|---|
| | | | Probability of the event* | Average number of π-mesons produced | |
| 3 | 3·5 $Mc^2$ | 1·2 | 7 | | ~ 1/17 |
| 4 | 7·0 | 2·5 | 9 | 1 | ~ 1/29 |
| 5 | 11·5 | 3·5 | 11 | 2·2 | ~ 1/34 |
| 6 | 16·9 | 4·4 | 12 | 2·3 | ~ 1/39 |

* The probability of the event when no heavy meson is produced is taken to be 100.

It will be noticed that, for collisions involving primary energies up to about 20 $Mc^2$, the possibility of a heavy meson being created is small. (The relative probability of two or more heavy mesons being created is very small and does not alter the conclusions drawn. For very high energies the above formula breaks down.) The slightly higher ratio of the number of heavy mesons to that of π-mesons, near the threshold energy for the creation of a heavy meson, will also be observed. This is due to the fact that, according to this theory, the probability of creation of a heavy meson varies more slowly with increasing energy than does the average number of π-mesons created.

In the extremely high energy region, where the heavy mesons and the nucleons have also to be treated in the extreme relativistic approximation, it follows from thermodynamic considerations[2] that the number of heavy mesons produced will be comparable to the average number of π-mesons, the ratio being governed mainly by the ratio of their respective statistical weight factors.

I am grateful to Mr. J. Hamilton for his interest in the work. I am also indebted to the Government of India for the award of a scholarship.

## Mean Square Radius of randomly coiled Molecular Chains

An expression for the mean square radius of a randomly coiled long-chain polymer, that is, for the mean square distance of its constituent groups from their centre of mass, was first derived by Debye[1]. Debye's formula applies only to very long chains; the following simple derivation is valid for any unbranched chain, provided the correlation between two atoms depends only on the number of links separating them (this implies neglect of the excluded volume effect).

According to a theorem by Lagrange[2], in a system of $n$ particles the mean square distance $R_n^2$ of the particles from their mass centre is given (in the case of equal masses) by:

$$R_n^2 = \sum_i r_{Gi}^2/n = \sum_{i,j} r_{ij}^2/n^2. \qquad (1)$$

Here the $r_{Gi}$ denote the distances of the individual particles from the mean centre and the $r_{ij}$ their mutual distances; the double sum has to be taken over all pairs of particles (once only). If the particles are arranged in the form of a chain and the average is taken over all possible configurations of the chain, equation (1) leads to:

$$n^2 < R_n^2 > = \Sigma < r_{ij}^2 > = (n-1) < r_{12}^2 > + (n-2) < r_{13}^2 > + \ldots + < r_{1n}^2 >, \qquad (2)$$

where the signs $< \; >$ denote statistical averages.

For links of constant length $l_0$ and mutually independent directions:

$$< r_{1j}^2 > = (j-1)\, l_0^2, \qquad (3)$$

which yields with the use of (2):

$$< R_n^2 > = \frac{1}{6}\, l_0^2\,(n - 1/n) = \frac{1}{6} < r_{1n}^2 > (1 + 1/n). \qquad (4)$$

For a constant valency angle $\pi - \omega$ and free rotation about bonds, it is known that[3]:

$$< r_{1j}^2 > = l_0^2 \left[ (j-1)\, \frac{1+\alpha}{1-\alpha} - 2\, \frac{\alpha - \alpha^j}{(1-\alpha)^2} \right], \qquad (5)$$

where $\alpha = \cos \omega$. Substitution of this into (2) yields

$$< R_n^2 > = \frac{l_0^2}{n^2} \left[ \frac{1}{6}\, \frac{1+\alpha}{1-\alpha}\,(n^3 - n) - \frac{(n-1)\alpha}{(1-\alpha)^2} \left( n - \frac{2\alpha}{1-\alpha} \right) - \frac{2\,(\alpha^3 - \alpha^{n+1})}{(1-\alpha)^4} \right]. \qquad (6)$$

More complicated correlations can be treated in an analogous way. In all cases in which there is no preferential tendency for the chain to develop in any specific direction in space, Debye's result[1] is obtained for large $n$, that is:

$$< R_n^2 > = < r_{1n}^2 > \left[ \frac{1}{6} + O\,(n^{-1}) \right]. \qquad (7)$$

The subject of this note formed part of the fundamental research programme of the British Rayon Research Association.

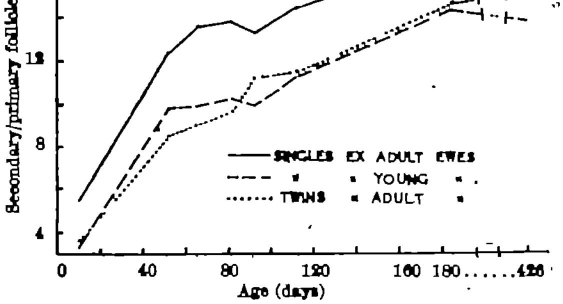
## Follicle Development in the Australian Merino

So far as we are aware, there is no published information of a quantitative nature on the post-natal development of the follicle population in the skin of the merino sheep, although Carter and Hardy[1] have presented quantitative data for the pre-natal period. In his classical description of the development of the follicle group, Carter[2] was concerned with descriptive morphology and ontogenic considerations rather than with quantitative aspects. His clear definition of the two follicle types (primary and secondary), their relative place in the developmental sequence, and their fundamental arrangement in group form lays the foundation on which quantitative considerations may be built. The most satisfactory measure of the progress of development of the follicle population is the ratio of secondary follicles to primary follicles ($S/P$). The validity of this unit rests on the observation (Carter[2]) that the primary population within any region is determined by approximately the eighty-sixth day of pre-natal life, and that only secondary follicles develop thereafter. While it has not been proved that no primary follicles develop after this time, the histological evidence is heavily in this direction.

Unpublished observations at this College on causes of variability in the skin and fleece of merino sheep have shown that, at fifteen months of age, the $S/P$ ratio of twins is frequently lower than that of singles, and those for the progeny of young ewes are also lower than those of mature ewes. It was decided, therefore, to study the development in these classes from early post-natal life. Skin sections were taken from the mid-side at 10, 52, 66, 82, 92, 113, 185 and 426 days of age, a single section of 1 cm. diameter being taken from each animal at each sampling period.

These sections were examined histologically by a method which was essentially the same as that described by Carter[2]. The accompanying graph shows the relationship between the $S/P$ ratio and age in three groups of lambs taken at random from a flock of South Australian (Bungaree) merino.

The consistently lower ratio in those groups subject to some nutritional penalty (twins and progeny of young ewes) is quite evident. Theoretically, it is not possible for the $S/P$ ratio to decline unless there is a loss of secondary follicles. Whether this is the cause of the three points showing a lower ratio than at the previous observation cannot be stated with certainty. Such a decline in ratio could also appear as a result of sampling variations, although this seems unlikely in view of the numbers involved. Of particular interest is the relatively large difference in the



$S/P$ ratio at ten days of age, when the first sections were taken. This difference appears to be too large to have developed since birth, and strongly suggests that the late pre-natal development of secondary follicles may be affected by the fœtal environment. In a further series of observations, a significant correlation ($r = 0 \cdot 56$) between birth-weight and $S/P$ ratio at birth has been noted, and seems to establish beyond doubt that the ratio at birth is influenced by the general pre-natal environment. Subsequent observations have also shown that the rate of development of secondary follicles during early post-natal life is closely associated with growth-rate in general and particularly with rate of expansion of skin.

These observations form part of a larger series being conducted at this College, and financed largely by the Commonwealth Scientific and Industrial Research Organization from the Wool Research Trust Account; grateful acknowledgment is made for this assistance. The detailed observations will be published elsewhere in due course.

## Inhibition of Populations of *Hæmonchus contortus* in Sheep fed on White Clover (*Trifolium repens*) High in Lotaustralin

Melville *et al.*[1] have shown that strains of New Zealand white clover (*Trifolium repens*) may contain up to 0·033 per cent hydrogen cyanide. It occurred to me that such a concentration might be lethal to internal parasites of sheep.

Preliminary *in vitro* experiments demonstrated that solutions of potassium cyanide, approximating to the concentration of hydrogen cyanide which could be expected in the rumen of sheep fed on white clover, killed some trichostrongylid infective larvæ. Further, some infective larvæ in water exposed over macerated clover also were killed.

A third step was to administer known populations of *Hæmonchus contortus* infective larvæ to lambs reared free from parasitism and fed on pure stands of the following plants: (1) New Zealand certified pedigree white clover, a strain selected and bred by the Grasslands Division of the Department of Scientific and Industrial Research, high in the cyanogenetic glucoside, lotaustralin; analysis at the initiation of the experiment revealed 0·023 per cent hydrogen cyanide. (2) Red clover (*T. pratense*) containing a doubtful trace of hydrogen cyanide (white clover of low cyanide content was not available at the time of the experiment). (3) Cocksfoot (*Dactylis glomerata*), a grass chosen because it was available and did not contain hydrogen cyanide.

Fourteen seven-month old Romney lambs were simultaneously placed in each of the three parasite-free experimental paddocks. The lambs were permitted four days to become accustomed to the diet, and then each was given 2,000 *H. contortus* infective larvæ. After fourteen more days in the paddocks, the lambs were killed and the *H. contortus* populations counted. Only fifth-instar parasites were found. The average *H. contortus* populations for the groups were: on white clover, 509·6 worms; on red clover, 613·9 worms; on cocksfoot, 698·6 worms. Thus the average populations of the white and the red clover groups were, respectively, 72·9 and 87·8 per cent of the cocksfoot group. The average differences required for significance between the groups at the 5 per cent and 1 per cent levels are, respectively, 121·9 and 163·1. Thus it is seen that there is a highly significant difference in worm populations between the white and the cocksfoot groups; but between these two groups and the red clover group, population differences do not reach the 5 per cent level of significance. There is doubt that cyanide content is the only factor involved. The work is being continued.

I am indebted to the following officers of the N.Z. Department of Scientific and Industrial Research: Messrs. L. Corkill, L. W. Gorman and P. Sears of the Grasslands Division, for provision of the experimental areas and plants; to Mr. J. G. Fraser of the same Division, for chemical analyses; and to Mr. A. C. Glenday of the Applied Mathematics Laboratory, for statistical treatment of data. The work is being financed with the aid of a grant from the Department of Scientific and Industrial Research.

## Action of Insulin on the Frog (*Rana temporaria*)

Earlier investigations of the action of insulin on cold-blooded vertebrates have shown that, although large doses usually lead to the appearance of typical convulsions, there is often a long latent period (1–2 days at room temperature) during which there are no visible symptoms[1–3]. In experiments performed in March and May 1952 the action of insulin on the blood-sugar level of the frog was followed, at intervals, from the time of injection to the development of convulsions. The frogs were kept at room temperature (17°–20° C.) and were injected with four units of insulin (Wellcome 40) in the dorsal lymph sac. The sugar content of the blood was determined by a modification of the method described by King[4] for obtaining "true sugar" values, which are 15–20 mgm./100 ml. lower than those previously recorded for the frog[5].

There was no change in the mean blood-sugar level in the first $1\frac{1}{2}$ hr. after insulin ($23 \pm 1 \cdot 81$ mgm./100 ml.), but after 5 hr. it had fallen to a very low value ($3 \pm 0 \cdot 69$ mgm./100 ml.), which was maintained to the end of the experiments when the frogs had shown typical insulin convulsions[1,2]. In one series of experiments (May 1952) parallel estimations of the glycogen content of the liver and gastrocnemius muscles were made (calculated as percentage wet weight of tissue). The mean muscle-glycogen content fell slightly between 5 hr. and 24 hr. after insulin (from $0 \cdot 53 \pm 0 \cdot 06$ to $0 \cdot 32 \pm 0 \cdot 06$ per cent, $P < 0 \cdot 05$), possibly followed by a further decrease associated with the occurrence of convulsions ($0 \cdot 23 \pm 0 \cdot 05$ per cent). The changes in liver-glycogen content in the first 24 hr. were not significant, but after convulsions had occurred there was a marked fall (from $1 \cdot 71 \pm 0 \cdot 13$ to $0 \cdot 36 \pm 0 \cdot 22$ per cent, $P < 0 \cdot 001$).

In the light of the above experimental results the following hypothesis is put forward to account for the delayed appearance of insulin convulsions in the frog. The first action of insulin is a marked depression of glycogenolysis in the liver[4,7], perhaps accompanied by increased uptake of glucose by the tissues, leading to the development of an extremely hypoglycæmic condition. The frog then utilizes its peripheral carbohydrate stores for its energy needs, as suggested by the decrease in muscle glycogen. In general, the carbohydrate reserves of the central nervous system are considerably lower than those of the muscles, and it may be assumed that they would be the first to be exhausted. When this occurs the typical insulin convulsion appears. These convulsions have been observed to be accompanied by marked temporary contraction of the melanophores[5], suggesting the release of adrenaline which presumably also causes mobilization of some of the liver glycogen. This glucose production by the liver is responsible for the rapid recovery of the frog, which then appears quite normal for a few hours. Eventually another convulsion occurs, and the cycle is apparently repeated until the liver reserves are exhausted, when death occurs. Such a hypothesis also accounts for the fact that the time required for the appearance of convulsions depends on the environmental temperature rather than on the dose of insulin[1,2]. It has, in fact, been pointed out that the graph of the rate of action of insulin at various temperatures corresponded very closely to the curve for oxygen consumption[1].

Experiments on fish have shown that there is a correlation between the rate of action of insulin and the activity of the fish[3], and also that in a given species the former varies with temperature[6]. This suggests that the mode of action of insulin in certain fishes may be similar to that proposed for the frog.

## Heat Inactivation of Strawberry Viruses

THE first and most effective measure for the control of virus diseases of strawberries is the provision of healthy planting material. Selection on the basis of virus tests has resulted in a virus-free clone of the Royal Sovereign variety and revived its commercial cultivation; but except for the recently bred variety Auchincruive Climax, no plants of other widely grown varieties have been found without at least a mild crinkle virus.

Experiments on heat therapy of strawberry plants infected with crinkle viruses were started in 1950, using a thermostatically controlled water-bath and a laboratory oven. It was found that although plants would survive only seven hours in water at 35° C., they would survive up to seven days in the oven at 33° C. Graft tests to the sensitive indicator, *Fragaria vesca*, in 1951 and again in 1952, showed that the mild crinkle virus had been inactivated in one plant (var. Perle de Prague) by oven treatment, and that one plant of Huxley's Giant had a reduced virus content.

In 1952, a propagation frame was adapted by the addition of thermostatically controlled heaters and double glazing, which gave temperature regulation within 2° C. In a series of experiments, young plants, growing in 3-in. pots and with all but the youngest leaf removed, were subjected to 37 ± 2° C. for periods ranging from five to twelve days. After a recovery period of about two weeks, the surviving plants were infested with non-infective aphids, *Pentatrichopus fragaefolii* Cock., which were transferred after 24 hr. to test plants (*Fragaria vesca*). Virus was always transmitted from unheated control plants in comparable tests. The heated plants which gave no virus transmission were re-tested with aphids, and those again yielding no virus were grafted to *F. vesca* plants. Apparently complete virus inactivation has occurred in plants of the varieties Early Cambridge, Huxley's Giant and Perle de Prague, and their clonal propagation is proceeding rapidly. The application of heat therapy to other varieties will follow.

Work on technique and on the determination of precise heat inactivation periods for different viruses is still in progress; the results obtained so far which may be useful to other investigators are summarized as follows.

The lowest temperature-time at which inactivation occurred was 33° C. for six days. Although some plants were killed, eight days at 37° C. gave the most reliable results; eleven days was the longest time any plant survived at this temperature.

Three viruses have been inactivated, which are, in the probable order of their sensitivity to heat: (*a*) an undescribed virus which causes severe leaf necrosis on Royal Sovereign and bud proliferation on *F. vesca*; (*b*) the mild crinkle virus (virus 1)[1]; and (*c*) the crinkle virus (virus 3)[2]. The yellow-edge virus (virus 2)[3] was not included in these experiments.

Plants previously thought, on the basis of vector and graft tests, to be infected with single viruses have been shown to contain at least two, one of which is inactivated more rapidly than the other.

Some plants which had given no virus transmission by aphids a few weeks after treatment gave transmissions when tested three months later, presumably owing to 'resurgence' of virus from deep-seated tissues.

Plants in the frame with daylight survived 37° C. for three days longer than did those in the dark oven. Warm water killed strawberry plants more quickly than did air at the same temperature, and plants survived longer incubation when the soil was moistened daily to prevent wilting than when saturated. Well-rooted plants withstood heat treatment better than recently potted plants.

The difference between varieties shown in the proportion of plants surviving heat treatment is thought to be due mainly to different susceptibility to fungal infection (for example, by *Botrytis cinerea*) under these conditions of high humidity and temperature. More plants survived in a sterile medium, 'Vermiculite', than in steam-sterilized soil.

## Cytoplasmic Particles in Bean Root Cells

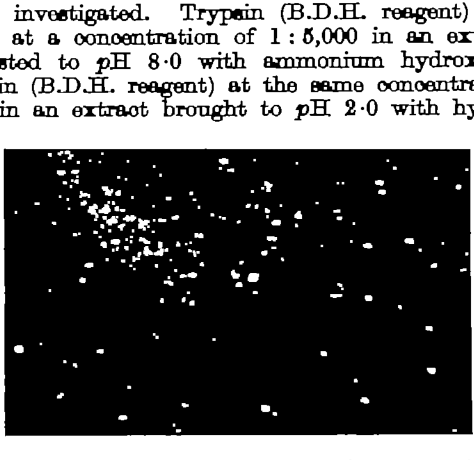
In the course of an investigation of the composition of certain aqueous extracts of tissues from the bean root, the material was examined in an electron microscope. Small spherical granules, slightly smaller in size than the microsomes described by Claude[1], Brachet and Jeener[2], and Stern[3], were detected. The size of the particles varied with the maturity of the tissue from which they were taken.

Bean seeds were germinated and sections cut from roots of standard length using the techniques previously described[4]. Aqueous extracts were prepared from sections cut from the regions 0–2·0; 7·0–9·0; and 13·0–15·0 mm. from the apex of the root. Each zone was cut into five 0·4-mm. fragments. The groups of sections were placed in petrol ether, stored overnight at + 4° C., and then washed, and ground with a glass pestle and mortar. 2·0 ml. of glass-distilled water was added and the resulting suspension centrifuged at approximately 5,500 $g$ for 45 min. Finally, the clear supernatant was diluted 5,000 times with glass-distilled water.

Silver-plated grids with 'Formvar' films were used as carriers in the electron microscope. A drop of fluid was transferred to the grid, and, after drying under reduced pressure in a vacuum desiccator over phosphorus pentoxide, the preparations were gold shadowed and examined in a Phillips electron microscope. Photographs were taken by Mr. G. W. Ripley at a magnification of × 20,000. The particle-size was measured after projecting the electron micrographs on to a screen.

The accompanying photograph shows a typical electron micrograph of particles from the apical zone of the root. Measurements showed average diameters for the particles from the three zones of 0–2·0, 7·0–9·0 and 13·0–15·0 mm., of 37 mμ, 24 mμ and 20 mμ, respectively. Clearly, the particles are largest in the meristematic cells and tend to decrease in size as the cell matures. It was found that a similar change occurred when fragments are excised and cultured on water at 25° C. for 48 hr. During culture the average diameter in tissue from the apical zone decreased from 36 to 28 mμ, and in the 13·0–15·0-mm. zone from 20 to 13 mμ.

Since particles similar to those described above have been found by earlier workers[1–3] to be composed of ribonucleoprotein, the effects of trypsin, pepsin and ribonuclease on the bean root particles were investigated. Trypsin (B.D.H. reagent) was used at a concentration of 1 : 5,000 in an extract adjusted to $p$H 8·0 with ammonium hydroxide; pepsin (B.D.H. reagent) at the same concentration but in an extract brought to $p$H 2·0 with hydrochloric acid; and ribonuclease (purified Armour Laboratories) at 1 : 10,000 in an untreated extract. Aliquots were incubated at 25° C. for 3, 8 and 21 hr. in each case with and without the enzyme. Extracts from the zone 0–2·0 mm. from the tip were used for these experiments.



Electron micrograph of cytoplasmic particles in aqueous extract of region 0–2·0 mm. from apex of bean root. Magnification on print, × 30,000

With the exception of the extract treated with trypsin, particles were present in all preparations even after 21 hr. incubation. With trypsin there was little change during the first 3 hr., but a marked change after 8 hr. At the end of 8 hr. incubation the particles had almost entirely disappeared. A similar effect was observed in the extract treated for 21 hr. with trypsin. These observations suggest that the particles are composed of protein. The result with ribonuclease does not eliminate the possibility that they may also carry ribonucleic acid. If the skeletal framework is protein, removal of ribonucleic acid may not affect the overall size.

It is probable that the particles are structural components of the cytoplasm. Their significance in the metabolism of the cell is not yet known. It may be noted, however, that the change in size accompanies corresponding changes in the rate of increase of protein and in the activities of certain enzyme systems.

Further work on the chemical composition and metabolic activity of the particles is in progress, and a detailed account will be given elsewhere.

We thank Dr. R. D. Preston for facilities for using the electron microscope and Mr. G. W. Ripley for technical assistance.

## Effect of Thyroid Gland on the Cultivation of *Amœba proteus*

A PRELIMINARY study of the effects of thyroid gland tablets on *Amœba proteus*, placed singly or in bulk in hollowed-out glass squares, having been made without any definite results, the whole of the resulting material was used for inoculating culture 12, boiled wheat grains being the pabulum. For many months the $p$H of this culture fluctuated around $p$H 4, and *Euglena* flourished. Bean and pea cotyledons were substituted as pabulum. Small amœbæ, length 10–20 μ, were now present in culture 12. Miguel's fluid was added and the $p$H rose to $p$H 6·2. After a few months had elapsed, adult *A. proteus* appeared, and culture 12 was so flourishing that it was divided up into sub-cultures. These cultures are readily distinguished from our stock cultures even by a biologist quite ignorant of their history by: (1) the larger size of the adult amœbæ in them, (2) the persistence of the adult stage beyond the normal span (the time occupied by the amœbæ to grow from newly hatched to sporulation stage is twelve months); and, therefore, (3) the rarer occurrence of developmental stages in the culture; (4) difficulty in making successful sub-cultures from the original.

Dr. T. G. Rennie having kindly procured thyroid tablets of the same strength as those used above, the experiments are being continued to see if a race of 'giant' *A. proteus* can be secured.

## University Botanical Teaching and Training

THE report of the discussion on botanical teaching held at the British Association meeting this year raises a number of interesting problems[1]. I cannot agree with Dr. Ashby when he suggests that the specific requirements of potential employers, and, in particular, government departments, should determine the scope and content of honours courses. I have heard similar arguments out here in New Zealand where government departments form the major avenue of employment for the abler students. It is surely our duty to see that students have a sound botanical, rather than a vocational botanical, training.

After acquaintance with several types of botanical training, and at the risk of appearing biased, I believe that something along the lines of the Cambridge system, as described by Prof. Briggs, meets several of the points raised and in particular has sufficient flexibility for the future specialists without losing the advantages to be gained from an overall education. The introduction of the half subjects, although regarded with suspicion by many at first, has, I think, been a happy proposal because it permits specialists to have a wider choice of ancillary subjects. I was surprised that no one raised the desirability of altering the present system in British universities where a subject tends to be studied as a unit over a whole year. The Cambridge half-subject system or the American semester system would merit much closer study in relation to the needs of present-day botanical teaching.

It might be of interest to refer to some organizational points at Auckland University College. Although there is no honours degree at the bachelor level, nevertheless the teaching is at the honours level. Certain prerequisites are laid down by the various heads of departments. Thus in botany a student who intends to study the subject for more than one year must do a year of chemistry before proceeding to study additional plant physiology. Any student taking the B.Sc. degree with botany as the major unit must, in addition, do one year in zoology. Those students who stay on to take an M.Sc. have not only a thesis to do but also there are additional lecture courses. These comprise formal courses in economic botany, history of botany and evolution, together with a number of topics selected from various fields of botany and changing from time to time. There are further prerequisites also; for example, a student specializing in genetics must have done a year of mathematics, a student in plant physiology is expected to have done a second or third year in chemistry, while an ecologist must attend a surveying course in the Geography Department. We also make use of specialists in other fields; for example, the professor of organic chemistry and the professor of geography both give some lectures in the course of economic botany.

Finally, the unit system at Auckland has great advantages, though it is not quite so flexible as the Cambridge system. Only one subject is studied over three years and at least one other subject over two years. This provides five units, and as eight are required for the degree the remainder can be taken as one-year courses in three other different subjects, or another subject can be taken to the second-year stage or one to a third-year stage. While this system provides very considerable flexibility, one must admit that it does raise time-table problems, though these can be solved.

---

THE main difficulty in botanical teaching lies in the fact that three or even four years of study are not enough to train a biologist for all the requirements of modern life.

In this Department the first year is devoted to a general survey, necessitated by the completely insufficient knowledge the students bring with them from the schools. Thereafter students may proceed with zoology as second major; but chemistry as second major is becoming increasingly popular. As I consider any specialization in the first three years to be undesirable, I think it would be better if those majoring in botany and zoology could have the opportunity of following biochemical courses in case their interest lies in this field.

In the second year, courses in systematics of lower and higher plants and in physiology are given. In the third year, the main courses are those in taxonomy, anatomy, cytology and plant breeding; but there are also short courses in ecology, and in phytogeography in relation to climatology. Practical ecology is taught during a fortnight's course at Frankenwald, the University's Pasture Research Station.

Students proceeding to the honours course (fourth year) find no prescribed syllabus. Considerable choice of subjects is made according to their special interests. The system is one of individual tuition and serves three purposes: (*a*) extension and broadening of knowledge in some of the fields studied in the first three years, (*b*) self-activity, by learning how to tackle problems and apply different techniques with criticism, (*c*) discovery of abilities. A course of this type stimulates the interest of the student, not only in his own work, but also in that of others.

In conformity with the principle of general biological training in the first three years, which is based upon the undeniable interrelationship of all facets of modern botany, we created a special honours course in 'bio-ecology'. This course is based on botany and zoology as majors and has ancillary subjects like surveying, statistics and geology.

Subjects like ecology and other border-line fields are very suitable to demonstrate the complexity of apparently simple problems.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

## Monday, February 16

Institution of Post Office Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Mr. F. C. Meade: "An Approach to the Economics of P.O. Engineering Training".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Dr. E. C. Willatts and Mrs. M. G. C. Newson: "Pattern of Population Trends in England and Wales".

Society of Chemical Industry, Crop Protection Panel of the Agriculture Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Papers on "Physical Factors in relation to Biological Activity of Insecticides".

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. T. S. Work: "Biosynthesis of Proteins".* (Further Lecture on February 20.)

Society of Chemical Industry, London Section (at the Royal Institution, 21 Albemarle Street, London, W.1), at 6 p.m.—Mr. J. H. Cummins: "The Development of Chemistry in Australia" (Jubilee Memorial Lecture).

Sheffield Metallurgical Association (joint meeting with the Local Section of the Institute of Metals, and the Society of Engineers and Metallurgists, in the University Building, St. George's Square, Sheffield), at 7 p.m.—Mr. W. A. Baker: "The Constitution and Properties of some Titanium-Base Alloys".

## Tuesday, February 17

Society of Chemical Industry, Agriculture Group (in the Chemistry Lecture Theatre, Royal College of Science, South Kensington, London, S.W.7), at 2.30 p.m.—Dr. A. Eden: "Substitute Feeding Stuffs".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. A. J. S. Pippard: "The Behaviour of Engineering Structures". (Further Lectures on February 24 and March 3.)

Physical Society, Low Temperature Group (joint meeting with the Institute of Refrigeration, at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Discussion on "Novel Refrigeration Cycles".*

University of London (in the Electrical Engineering Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. M. V. Wilkes: "The Design of Electronic Digital Computers".* (Further Lectures on February 24, March 3 and 10.)

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. A. H. Yates: "Recent Developments in Gliding".

Royal Society of Medicine, Pathology Section (at 1 Wimpole Street, London, W.1), at 7.45 p.m.—Symposium on "Hæmoglobin Metabolism".

## Wednesday, February 18

Society of Chemical Industry, Corrosion Group (joint meeting with the Newcastle Section of the S.C.I., and the Chemical Engineering Group, in the Stephenson Building, King's College, Newcastle-upon-Tyne), at 2.30 p.m.—Dr. W. H. J. Vernon: "Some Recent Progress in Corrosion Research"; at 6 p.m.—Mr. K. A. Spencer and Dr. H. B. Footner: "Protective Coatings for Buried Pipelines".

Physical Society, Colour Group (at the Institute of Ophthalmology, Judd Street, London, W.C.1), at 3.30 p.m.—Scientific Papers.

Eugenics Society (at Manson House, 26 Portland Place, London, W.1), at 5 p.m.—Prof. T. H. Marshall: "Social Selection in the Welfare State" (Galton Lecture).*

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Scientific Papers.

Physical Society, Acoustics Group (at the Science Museum, Exhibition Road, London, S.W.7), at 5.15 p.m.—Mr. D. H. Follett: Demonstration of some Old Instruments—Musical and Otherwise—from the Acoustics Collection in the Science Museum.

Royal Microscopical Society (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. M. H. F. Wilkins: "The Performance of Spherical-Mirror Reflecting Objectives when used for Ultra-Violet Photomicrography".

University of London School of Pharmacy (in the Chemistry Lecture Theatre, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Sir Henry Dale, O.M., F.R.S.: "The Future of Pharmacy and Pharmacology" (Charter Lecture).*

Institution of Electrical Engineers (at Central Hall, Westminster, London, S.W.1), at 6.30 p.m.—Mr. A. R. Cooper: "Light from the Dark Ages, or the Evolution of Electricity Supply" (Faraday Lecture). (Admission by ticket obtainable from the Institution.)

Royal Institute of Chemistry, London Section (joint meeting with the British Association of Chemists, at the Wellcome Research Institution, 183 Euston Road, London, N.W.1), at 6.30 p.m.—Prof. C. K. Ingold, F.R.S., and others: A Discussion on "Education in Chemistry".*

Institute of Petroleum, Stanlow Branch (joint meeting with the North-Western Section of the Institute of Fuel, at the Grosvenor Hotel, Chester), at 7.30 p.m.—Mr. S. J. Young: "Methane at Point of Ayr Colliery".*

## Thursday, February 19

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 4.45 p.m.—Prof. V. B. Wigglesworth, F.R.S.: "Chemical Aspects of Insect Physiology".* (Further Lectures on February 26, March 5 and 12.)

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. J. S. Sheppard: "Precise Azimuths from Steep Sights"; Mr. R. Daniel: "Diamond Mining Practice in Kimberley, South Africa".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Captain Cyril Diver, and others: "Nature Conservancy".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. G. de Rham: "On some Plane Curves which are defined by certain Functional Equations".

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Mr. V. W. Turner: "Village Structure of the Mwinilunga Lunda".

Society of Chemical Industry, Road and Building Materials Group (at the Building Centre, Store Street, London, W.C.1), at 6 p.m.—Dr. B. H. Knight: "The Stability of Asphalt Mixtures as affected by Aggregate Size".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. M. A. C. Dowling: "The Malaria Eradication Experiment in Mauritius".

University of London (in the Swanley Hall, Wye College, Wye, Ashford), at 8.15 p.m.—Prof. W. Arthur Lewis: "The Economic Development of Under-developed Countries".*

## Friday, February 20

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Capt. R. C. Alabaster: "Navigation and the Operation of Jet Aircraft".

Institution of Mechanical Engineers (joint meeting with the Applied Mechanics Group, at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr. K. H. R. Wright: "An Investigation of Fretting Corrosion".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Dr. D. P. Cuthbertson: "Problems of Quality and Quantity of Protein".*

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Discussion on "Circuit Conventions, with particular reference to Alternating-Current Circuit Vector Diagrams" (to be opened by Mr. J. G. Fleming).

British Institute of Radiology (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 6.30 p.m.—Mr. A. Nemet and Mr. W. B. Cox: "The Contrast Problem in High Kilovoltage Radiography".

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Scientific Papers.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Rt. Hon. Lord Brabazon of Tara: "The Birth of Flight".

## Saturday, February 21

Biochemical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 11 a.m.—Symposium on "Biological Transformations of Starch and Cellulose".
